Chapter 1. DB-Access User's Guide

This publication describes how to use the DB-Access utility to access, modify, and retrieve information from Informix® database servers. The *Informix® DB-Access User's Guide* describes how to use the DB-Access utility to access, modify, and retrieve information from Informix® database servers.

 **Important:** Use DB-Access with the current version of the Informix® database server. If you use DB-Access with a database server from a different version, you might obtain inconsistent results, such as when you use a version that does not support long identifiers with a version that does.

This publication is written for the following users:

- Database users
- Database administrators
- Database-application programmers

This publication assumes that you have the following background:

- A working knowledge of your computer, your operating system, and the utilities that your operating system provides
- Some experience working with relational databases or exposure to database concepts
- Some experience with computer programming

These topics are taken from *Informix® DB-Access User's Guide*.

What's new for DB-Access in HCL Informix, Version 12.10

This publication includes information about new features and changes in existing functionality.

Table 1. What's new in DB-Access for HCL Informix, Version 12.10.xC8

Overview	Reference
	dbaccess command: Start DB-Access on page 8

Getting started with DB-Access

DB-Access provides a menu-driven interface for entering, running, and debugging Structured Query Language (SQL) statements and Stored Procedure Language (SPL) routines. You can also run DB-Access interactively from the command line.

You use SQL and SPL commands to perform data-definition tasks, such as specifying the number and type of data columns in a table, and data-management tasks, such as storing, viewing, and changing table data.

You can use DB-Access for the following aspects of database processing:

- Running ad hoc queries that you run infrequently
- Connecting to one or more databases, transferring data between the database and external text files, and displaying information about a database
- Displaying system catalog tables and the Information Schema of databases
- Practicing the SQL and SPL statements and examples that are provided in the *Informix® Guide to SQL: Tutorial* or the *Informix® Database Design and Implementation Guide*
- Testing applications that you intend to store for use in a production environment
- Creating demonstration databases

Important: DB-Access is not intended as an application-development environment. You cannot branch conditionally or loop through SQL statements when you run them within DB-Access.

The DB-Access utility is included with the Informix® server and with the Informix® Client Software Development Kit.

The OpenAdmin Tool (OAT) for Informix® is an alternative to the DB-Access utility.

Requirements for the Informix® server DB-Access utility

Before you start DB-Access, prepare the Informix® server environment.

Do the following tasks before you start the DB-Access utility that is included with the Informix® server:

- Set environment variables
- If you require globalization, set up the Global Language Support (GLS) locale
- Start the database server

To secure DB-Access connections with Informix®, you can use the Secure Sockets Layer (SSL) protocol.

Related information

[Secure sockets layer protocol on page](#)

Environment variables for DB-Access

As part of the installation and setup process, the system or database administrator sets certain environment variables that enable Informix® products to work within a particular operating-system environment.

You must have `$INFORMIXDIR/bin` in your path if you use DB-Access on a UNIX™ operating system or `%INFORMIXDIR%\bin` in your path if you use DB-Access on a Windows™ operating system. Your operating system uses the path to locate the initialization script and the `dbaccess` executable file.

In a UNIX™ environment, the database server must have the appropriate terminal that is set up from among the terminals that are listed by the **INFORMIXTERM** environment variable.

DB-Access uses the terminal definitions in the `terminfo` directory unless the **INFORMIXTERM** environment variable is set to the `termcap` file. If DB-Access fails to initialize the menus that are based on the **INFORMIXTERM** setting, DB-Access tries to use the other setting. For example, if DB-Access fails to initialize the menus using the `terminfo` directory, DB-Access starts the menus using the `termcap` file.

You can set the following optional environment variables:

DBACCNOIGN

Rolls back an incomplete transaction if you run the LOAD command in menu mode.

DBCENTURY

Sets the appropriate expansion for DATE and DATETIME values that have only a two-digit year, such as 04/15/12.

DBDATE

Specifies the user formats of DATE values.

DBEDIT

Sets the default DB-Access text editor without changing the default text editor that is associated with the operating-system shell.

For more information about how DB-Access uses the text editor that you specify as default, see [A system editor on page 21](#).

DBFLTMASK

Sets the default floating-point values of data types FLOAT, SMALLFLOAT, and DECIMAL within a 14-character buffer.

The effect of this variable is limited to the DB-Access display size for numbers.

DELIMIDENT

Causes the database server to interpret double quoted (") text as identifiers rather than strings.

IFX_LONGID

Determines whether a client application can handle long identifiers.

If you use the **IFX_LONGID** environment variable to support SQL identifiers with up to 128 bytes, some error, warning, or other messages of DB-Access might truncate database object names that include more than 18 bytes in their identifiers. You can avoid this truncation by not declaring names that have more than 18 bytes.

GL_DATETIME

Defines the end-user formats for data values in DATETIME columns. In databases where **GL_DATETIME** has a nondefault setting, you must also set the **USE_DTEENV** environment variable to `1` for user formats to be applied correctly in some load and unload operations.

 **Important:**

The `%F` directive implies no default separator between the SECOND and FRACTION fields of DATETIME values. Defining no separator before the `%F` directive concatenates SECOND and FRACTION values, as in the following example, where **GL_DATETIME** has this setting:

```
%Y-%m-%d %H:%M:%S%F
```

Below is the end-user display for a DATETIME YEAR TO FRACTION(2) value on August 23, 2013, at exactly 53 seconds after 1:15 PM:

```
2013-08-23 13:15:5300
```

Here `5300` represents 53 seconds, concatenated with the FRACTION precision of 2. To display a separator between the integer and fractional parts of the seconds value, your **GL_DATETIME** setting must include a literal separator character immediately before the `%F` formatting directive.

Related information

[Environment variables on page](#)

Requirements for the Informix® Client Software Development Kit DB-Access utility

Before you start DB-Access on a client, set up the client environment.

The DB-Access utility on a client can directly access Informix® databases with which Client SDK has a client/server connection.

Do the following tasks before you start DB-Access utility that is included with Client SDK:

- Set the client/server connectivity information in the `sqlhosts` file.
 - If you renamed the file or moved it from the default location, set the `INFORMIXSQLHOSTS` environment variable to the full path name and file name of the file that contains the connectivity information.
 - You can use the `syncsqlhosts` utility to convert connection information from the Windows™ registry format to the `sqlhosts` file format.
- Set the `sqlhosts` information.
- Set the `INFORMIXDIR` environment variable to the Client SDK installation directory.
- Set the `INFORMIXSERVER` environment variable for a default server name.

Demonstration databases

You can practice using DB-Access with a demonstration database.

If you use Informix® demonstration databases, you can add, delete, or change the provided data and scripts. You can restore the database to its original condition.

You can configure the following demonstration databases:

- The **stores_demo** database illustrates a relational schema with tables about a fictitious wholesale sporting-goods distributor, as well as other tables that are used in examples. Tables containing electricity usage and geographical location data illustrate time series and spatial information. Tables containing electricity usage data illustrate time series information. Many examples in Informix® manuals are based on the **stores_demo** database.
- The **superstores_demo** database illustrates an object-relational schema. The **superstores_demo** database contains examples of extended data types, type and table inheritance, and user-defined routines.

The scripts that you use to install the demonstration databases are in the `$INFORMIXDIR/bin` directory on UNIX™ and in the `%INFORMIXDIR%\bin` directory on Windows™.

Some operating systems require that you have execute permissions to run SQL command files, read permissions to open these files or their contents in DB-Access, or write permissions to save modified or new files. Use the UNIX™ `chmod` command to enable execution of the SQL files that the initialization script installed.

The demonstration scripts are designed for the default locale. If you use a non-default locale, such as **en_us.utf8**, some features, such as the `SET COLLATION` statement, might not function correctly.

[The superstores_demo database on page](#)

Creating a demonstration database

You create demonstration databases by running the `dbaccessdemo` command.

About this task

When you create a demonstration database, the script confirms that you want to copy sample SQL command files.

Command files that the demonstration database includes have a `.sql` extension and contain sample SQL statements that you can use.

To create a demonstration database:

1. Create a directory.

You must have UNIX™ read and execute permissions for each directory in the path name that you create.

2. Change directories to the new directory and run the `dbaccessdemo` or `dbaccessdemo_ud` command.
3. The initialization script displays a series of messages on the screen as the database is created. Press **Y** to copy the command files into the directory that you created.

Result

The demonstration database is created. You are the owner and database administrator (DBA) of that database.

Results

If you want to discard changes that you made to your database or to the command files, rerun the `dbaccessdemo` or `dbaccessdemo_ud` command and press **Y** to replace the existing command files with the original versions.

dbaccessdemo command: Create demonstration databases

Use the `dbaccessdemo` or `dbaccessdemo_ud` command to create the demonstration databases.

Syntax for `stores_demo`

```
dbaccessdemo
-log
dbname
-dbspace dbspace_name
-nots
```

Syntax for `superstores_demo`

```
dbaccessdemo_ud
-log
dbname
-dbspace dbspace_name
```

-log

Requests transaction logging for the demonstration database.

dbname

Substitutes for the default database name. Must follow Identifier naming guidelines.

-dbspace

Requests a particular `dbspace` location for the demonstration database.

dbspace_name

Houses the demonstration database. If you do not specify a `dbspace` name, by default, the data for the database is put in the root `dbspace`. To create a `dbspace`, use the `onspaces` utility.

-nots

Prevents the creation of the time series tables in the **stores_demo** database.

Examples

The following command creates a database that is named **stores_demo**:

```
dbaccessdemo
```

The following example creates an instance of the **stores_demo** database named **demo_db**:

```
dbaccessdemo demo_db
```

The following command initializes the **stores_demo** database and also initiates log transactions:

```
dbaccessdemo -log
```

The following command creates an instance of the **stores_demo** database named **demo_db** in **dbspace_2**:

```
dbaccessdemo demo_db -dbspace dbspace_2
```

The following command creates a database that is named **superstores_demo**:

```
dbaccessdemo_ud
```

[Identifier on page](#)

Start DB-Access

You start DB-Access by running the `dbaccess` command from the command line. You can choose whether to use the DB-Access menu interface or the command-line interface.

You can start and use DB-Access in the following ways:

- Start DB-Access at the main menu.
- Start DB-Access from a specific menu or screen.
- Run a file that contains SQL statements without showing the DB-Access menus.
- Start and run DB-Access interactively at the command line, without the menu interface.

On Windows™, you can set up the DB-Access program icon to run any of the `dbaccess` commands.

If the **TERM**, **TERMCAP**, or **TERMINFO** environment variables on UNIX™ do not enable DB-Access to recognize the type of terminal you use, the main menu does not show. Instead, a message similar to the following text is displayed:

```
Unknown terminal type.
```

If you use a window interface on a UNIX™ terminal, issue the `dbaccess` command from a nonscrolling console window.

If you use a Windows™ terminal to run DB-Access on a UNIX™ database server, the terminal-emulation window must emulate a terminal type that DB-Access can recognize, or the database server shows an unknown terminal-type message in the terminal-emulation window.

Tip: If your operating system cannot find dbaccess, include the full path before the program name, as follows:

```
$INFORMIXDIR/bin/dbaccess
```

Related information

[Environment variables on page](#)

[Requirements for the Informix Client Software Development Kit DB-Access utility on page 4](#)

dbaccess command: Start DB-Access

Use the dbaccess command to start DB-Access. Include options to specify the database, command files, or to go to a specific menu screen.

Syntax

```

dbaccess
-ansi
-X
database
@server
-q
QUERY-LANGUAGE menu options 1
filename table
-t
TABLE menu options 2
table
-d
DATABASE menu options 3
-c
CONNECTION menu options 4
-s
-e -m
database -
filename
-a
5 -version -V -history

```

The dbaccess command without options starts the main menu with no database selected and no options activated. You select submenus from the main menu.

-ansi

Causes DB-Access to generate a warning whenever it encounters Informix® extension to ANSI-compliant syntax. For more information, see [Example: Check for ANSI compliance on page 15](#).

-a

Stops a process directly after the first error is encountered. Stopping a process from continuing after the first error can ensure greater database consistency.

-c

Starts with the CONNECTION menu as the top-level menu.

1. See [QUERY-LANGUAGE menu options on page 12](#).
2. See [TABLE menu options on page 13](#).
3. See [DATABASE menu options on page 11](#).
4. See [CONNECTION menu options on page 11](#).
5. Cannot be combined with any other option.

-d

Starts with the DATABASE menu as the top-level menu.

-e

Echoes each line from a command file designated by *filename*.

-history

Can be abbreviated to *-his*. Displays the previous commands that you ran from the dbaccess command line during the current session. Commands that you ran from the menu interfaces are not shown. Each command is numbered. In the interactive mode without menus, you can rerun previous commands with the following command:

```
run number
```

The *number* is the number of the command to run. For an example, see [Run DB-Access in interactive mode without menus on page 16](#).

-m

Displays all error messages generated by multiple levels of the server that pertain to an SQL statement in command files.

-q

Starts at the query-language menu (SQL-menu) as the top-level menu.

-s

Connects you to the main DB-Access menu and displays information about the current session.

This information includes database server name, database server type, the host computer, server capabilities, and other settings.

-t

Starts at the TABLE menu as the top-level menu.

-V

Displays the version number and serial number for DB-Access without launching the application. You cannot use any other options with *-V*.

-version

Displays the version number and build information for DB-Access, including the GLS library version, without launching the application. You cannot use any other options with *-version*.

-X

Activates the hexadecimal format for LOAD and UNLOAD statements.

database

Name of the database that you want DB-Access to connect to at the startup of your current session. A hyphen (-) indicates that the database is specified in a DATABASE statement in a command file.

filename

Names a command file to load with the SQL menu.

server

Name of the database server.

table

Specifies a table in the database.

If you exit from a submenu or option that you specified from the command line, you will exit directly to the operating-system command line.

CONNECTION menu options

The CONNECTION menu options for the dbaccess command represent short cut keys for the CONNECTION menu.

-cc

Chooses the Connect option on the CONNECTION menu.

-cd

Chooses the Disconnect option on the CONNECTION menu.

DATABASE menu options

The DATABASE menu options for the dbaccess command represent short cut keys for the DATABASE menu.

-dc

Chooses the Create option on the DATABASE menu.

-dcl

Takes you to the LOG option on the CREATE DATABASE menu

-dd

Chooses the Drop option on the DATABASE menu.

-di

Chooses the Info option on the DATABASE menu. With this option, you can add another letter as follows to go to the next menu level and view:

-dib

The dbspaces information for the current database

-din

The NLS information for the current database

-dip

Stored procedures in the current database

If you do not include a database name before any **-di** option, you must choose a current database from the SELECT DATABASE screen.

-dl

Chooses the CClose option on the DATABASE menu.

-ds

Chooses the Select option on the DATABASE menu.

QUERY-LANGUAGE menu options

The QUERY-LANGUAGE menu options for the dbaccess command represent short cut keys for the QUERY-LANGUAGE menu.

-qc

Chooses the Choose option on the SQL menu.

-qd

Chooses the Drop option on the SQL menu.

-qi

Chooses the Info option on the SQL menu. With this option, you can add another letter as shown in the following list (and specify a table) to go to the next menu level and view:

-qic

Columns in the table

-qif

Information about fragmentation strategy for the table

-qig

Information about triggers in the table

-qii

Indexes on the table

-qio

Table constraints

-qip

Access privileges on the table

-qir

Table-level references privilege on the table

-qis

Table status information

If you do not include a table name with the **-qi** option, you must choose one from the INFO FOR TABLE screen.

-qm

Chooses the Modify option on the SQL menu.

-qn

Chooses the New option on the SQL menu.

-qs

Chooses the Save option on the SQL menu.

-qu

Chooses the Use-editor option on the SQL menu.

If you do not include a database name before a **-q** option, you must choose a current database from the SELECT DATABASE screen.

When you select the Modify option on the QUERY-LANGUAGE menu, you must first select a command file to modify from the CHOOSE menu. The MODIFY screen is then displayed and shows the text.

Restriction: You cannot go directly to the Run or Output option on the SQL menu. Trying to do so results in an error message.

TABLE menu options

The TABLE menu options for the dbaccess command represent short cut keys for the TABLE menu.

-ta

Chooses the Alter option on the TABLE menu.

-tc

Chooses the Create option on the TABLE menu.

-td

Chooses the Drop option on the TABLE menu.

-ti

Chooses the Info option on the TABLE menu. With this option, you can add another letter as shown in the following list (and specify a table) to go to the next menu level and view:

-tic

Columns in the table

- tif**
Information about fragmentation strategy for the table
- tig**
Information about triggers in the table
- tii**
Indexes on the table
- tio**
Table constraints
- tip**
Access privileges on the table
- tir**
Table-level references privilege on the table
- tis**
Table status information

If you do not include a table name with the **-ti** option, you must choose one from the INFO FOR TABLE screen.

If you do not include a database name before a **-t** option, you must choose a current database from the SELECT DATABASE screen.

Example: Start DB-Access for a database

This example shows how to start DB-Access and specify a database to which to connect.

Assume that the database server that you have online contains a database named **mystores**. To make the **mystores** database the current database, start DB-Access with the following command:

```
dbaccess mystores
```

You can specify a database on a database server that is not online. For example, either of the following commands selects the **newstores** database on the **xyz** database server:

```
dbaccess newstores@xyz
dbaccess //xyz/newstores
```

When DB-Access starts, the database and database server name that you specify are displayed on the dashed line, as the following figure shows.

Figure 1. The DB-Access main menu with database and database server name

```
DB-Access:  Query-language  Connection  Database  Table  Session  Exit

----- newstores@xyz -----Press CTRL-W for Help ---
```

Example: Run a command file

This example shows how to start DB-Access and run a command file that contains SQL statements.

The following sample command runs the SQL statements in a file named `sel_stock.sql` on the **mystores** database:

```
dbaccess mystores sel_stock
```

The following sample command runs the SQL statements in the `sel_all.sql` file on the database that file specifies:

```
dbaccess - sel_all.sql
```

Some operating systems require that you have execute permissions to run SQL command files, read permissions to open these files or their contents in DB-Access, or write permissions to save modified or new files.

Use the UNIX™ `chmod` command to enable execution of the SQL files that the initialization script installed.

Example: View the Information Schema

This example shows how to start DB-Access and view the Information Schema for the specified database.

The `xpg4_is.sql` file in the `$INFORMIXDIR/etc` directory creates the Information Schema and installs the views for a specified database. The following command creates the Information Schema for database **mystores**:

```
dbaccess mystores $INFORMIXDIR/etc/xpg4_is.sql
```

The Information Schema adds to the database four information-only views that conform to X/Open XPG4 with Informix® extensions. After you run `xpg4_is.sql`, use DB-Access to retrieve information about the tables and columns that you have access to in the specified database.

 **Tip:** Do not install XPG4-compliant views on an ANSI database, because the format of XPG4-compliant views differs considerably from the format of the ANSI-compliant Information Schema views that are defined by the SQL standards committee.

Related information

[Information Schema on page](#)

Example: Check for ANSI compliance

This example shows how to start DB-Access and check whether a database is ANSI-compliant.

To check your SQL statements for compliance with ANSI standards, include the `-ansi` option or set the **DBANSIWARN** environment variable. Use the `-ansi` option with other `dbaccess` options such as `-dc` (to create a database), `-tc` or `-ta` (to create or alter a table), or `-qc filename` (to choose a command file). The following command checks for ANSI compliance while DB-Access creates the database **research**:

```
dbaccess -ansi -dc research
```

You do not need to specify the `-ansi` option on the command line if the **DBANSIWARN** environment variable is set.

DB-Access displays the SQLSTATE value with the warning under the following circumstances:

- You include the `-ansi` option or set the **DBANSIWARN** environment variable.
- You access or create an ANSI database.
- You run DB-Access in command-line mode or specify a `.sql` input file.
- Running an SQL statement generates a warning rather than an error.

Related information

[DECIMAL\(p\) Floating Point on page](#)

[GET DIAGNOSTICS statement on page](#)

[DBANSIWARN environment variable on page](#)

[ANSI-Compliant Databases on page](#)

Example: Show nonprintable characters in hexadecimal

This example starts DB-Access and activates the hexadecimal load and unload format (XLUF) so that the LOAD and UNLOAD SQL statements can format nonprintable ASCII signs in hexadecimal format.

The following command activates the XLUF format for the **mystores** database:

```
dbaccess -X mystores
```

A `.unl` file that the UNLOAD statement produces contains the hexadecimal format changes.

Related information

[The LOAD and UNLOAD statements on page](#)

Run DB-Access in interactive mode without menus

If you do not want to use the menus and do not have a prepared SQL file, use your keyboard or standard input device to enter SQL statements from the command line.

When you start DB-Access without a menu argument and with a hyphen as the final argument, DB-Access processes commands from the standard input device (on UNIX™) or the keyboard (on Windows™). DB-Access reads what you type until you indicate that the input is completed. Then DB-Access processes your input and writes the results to the standard output device (on UNIX™), or the command window (on Windows™).

DB-Access reads and runs SQL statements from the terminal keyboard interactively. While DB-Access runs interactively, the greater than (>) prompt marks the line where you type your next SQL statement.

When you type a semicolon (;) to end a single SQL statement, DB-Access processes that statement. When you press **CTRL-D** to end the interactive session, DB-Access stops running. The following example shows user input and results in an interactive session:

```
dbaccess - -
>database stores_demo;

Database selected.

>select count(*) from systables;

(count(*))

      21

1 row(s) retrieved.

>^D

dbaccess - -
>database stores_demo;

Database selected.

>select count(*) from systables;

(count(*))

      21

1 row(s) retrieved.

>^D
```

Batch command input (UNIX™)

You can use an inline shell script to supply one or more SQL statements. For example, you can use the UNIX™ C, Bourne, or Korn shell with inline standard input files:

```
dbaccess mystores- <<EOT!
select avg(customer_num) from customer
where fname matches '[A-G]*';
EOT!
```

You can use a pipe to supply SQL statements, as in this UNIX™ example:

```
echo 'select count(*) from systables' | dbaccess mystores
```

DB-Access interprets any line that begins with an exclamation mark (!) as a shell command. You can mix shell escape lines with SQL statements and put them in SQL statements, as follows:

```
dbaccess mystores -
>select
!echo hello
>hello
count(*) from systables;
>
```

```
(count(*))
      21
1 row(s) retrieved.
>
```

View and rerun DB-Access commands

You can view and rerun DB-Access commands that you ran from the command line during the current session.

To view the previous commands, run the `dbaccess -history` command. In the following example, the command history shows three previous commands:

```
dbaccess -history - -
1> create database sales_demo;

Database created.

2> create table customer (
2>     customer_code integer,
2>     customer_name char(31),
2>     company_name char(20));

Table created.

3> insert into customer values (102, "Carole Sadler", "Sports Spot");

1 row(s) inserted.

4> history;

1  create database sales_demo
2  create table customer (
    customer_code integer,
    customer_name char(31),
    company_name char(20))
3  insert into customer values (102, "Carole Sadler", "Sports Spot")
```

You can rerun the third command by running the `run 3` command:

```
4> run 3;

1 row(s) inserted.
```

Connect to a database environment in interactive mode

You can use the `CONNECT . . . USER` syntax in SQL statements that you issue in interactive mode. However, DB-Access does not support the `USER` clause of the `CONNECT` statement when you connect to a default database server.

When you include the `USER 'user identifier'` clause in a `CONNECT` statement in interactive mode, DB-Access prompts you to enter a password.

The following two command examples show how to connect to a database server in interactive mode. The first example uses the `CONNECT` statement without specifying a user identifier.

```
dbaccess -nohistory- -
> connect to '@starfish';
Connected.
```

If you include the `USER` clause in a `CONNECT` statement, as the second example shows, DB-Access uses echo suppression to prompt you for a password:

```
> connect to '@starfish' user 'marae';
ENTER PASSWORD:
Connected.
```

Restriction: For security reasons, do not enter the password on the screen where it can be seen. Also, do not include the `USING password` clause in a `CONNECT` statement when you use DB-Access interactively. If you are in interactive mode and attempt to enter a password before the prompt, an error message is displayed.

You can run the `USER` clause of a `CONNECT` statement in a DB-Access file that includes the `USER` clause. The following example uses a command file that contains a `CONNECT` statement with a `USING` clause to connect to a database server:

```
dbaccess - connfile.sql
```

Important: An SQL command file that contains the following statement is protected from access by anyone other than the `user_id` that the `USER` clause identifies:

```
CONNECT TO '@dbserver' USER 'user_id' USING password
```

For UNIX™, the following example uses a shell file to connect to a database server. DB-Access prompts you for a password.

```
dbaccess - - <<\!
connect to '@starfish' user 'marae';
!
ENTER PASSWORD:
```

Here the delimiting quotation marks preserve letter case in the database server name and in the authorization identifier of the user.

The full-screen menu interface

The DB-Access full-screen menu interface guides you through running SQL statements.

The DB-Access user interface combines the following features:

- A hierarchy of menus
- Screens that prompt you for brief responses and choices from selection lists

- Contextual HELP screens
- The interactive Schema Editor that helps you structure tables
- An SQL programmer environment, which includes the following features:
 - The built-in SQL editor where you enter and modify SQL and SPL statements
 - An option to use another editor of your choice
 - The database server syntax checker and runtime debugger
 - Storage, retrieval, and execution of SQL and SPL routines
- A choice of output for database queries and reports

The Query-language option

Use the Query-language option to enter, modify, save, retrieve, and run SQL statements. DB-Access retains the statements, if any, in the editor. These statements are called the *current* statements.

Use the Query-language option to:

- Learn SQL and SPL.
 - For example, use the Query-language option to practice the examples in the *Informix® Guide to SQL: Tutorial*.
- Create and alter table structures as an alternative to the DB-Access Schema Editor.
- Select, display, add, update, and delete data.

The SQL menu has the following options.

Option	Purpose
New	Clears current statements and positions cursor in SQL editor.
Run	Runs current SQL statements. A message is displayed or the data that is retrieved by a query is displayed with the number of rows retrieved.
Modify	Allows you to modify current SQL statements in SQL editor.
Use-editor	Starts a system editor so that you can modify current statements or create new statements. Use-editor is interchangeable with New and Modify.
Output	Redirects Run-option output to a file, printer, or system pipe.
Choose	Lists SQL command files so that you can choose a file to run or modify.
Save	Saves current SQL statements in a file for later use.
Info	Shows table information, such as columns, indexes, privileges, constraints, triggers, status, and fragmentation strategy.
Drop	Deletes a specified SQL command file.
Exit	Returns to main menu.

SQL editor

When you choose the New or Modify option, you see the SQL editor. You can type as many lines of text as you need. You are not limited by the size of the screen, although you might be limited by the memory constraints of your system. If you do not use the Save option to save your typed statements, they are deleted when you select an option that clears the SQL editor (such as New or Choose).

The SQL editor does not display more than 80 characters on a line and does not wrap lines.

- If you choose an existing command file in which the characters in a line extend beyond the 80th column, DB-Access displays a percent sign (%) in the 80th column to indicate an overflow. You cannot see all the characters beyond the percent sign, but the statement runs correctly.
- If you type characters in a new command file so that a line extends beyond the 80th column, DB-Access overwrites all the characters in the 80th column. You cannot see the overflow, and the statement does *not* run correctly.

To make the full text show on the screen, press **Enter** at a logical place in the first 80 characters of each line.

If you must type a quoted character string that exceeds 80 characters, such as an insert into a long CHAR column, use a system editor instead of the SQL editor.

If you want to include comments in the text:

- Use double minus signs for ANSI-compliant databases.
- Preface each comment line with a double minus sign (--) comment indicator. The comment indicator spans the entire line.
- Use braces ({}) for databases that are not ANSI-compliant. Enclose the entire comment indicator between the braces.

A system editor

When you want to enter or modify a long SQL statement or series of statements, you might prefer the flexibility and familiarity of a system editor to the SQL editor. Select the Use-editor option from the SQL menu to use the system editor.

If you have not set the **DBEDIT** environment variable, you must select a text editor to use for the session. If you select Use-editor, DB-Access prompts you to accept or override the default system editor once each session.

The default editor that DB-Access displays depends on the preference that you establish for your operating system:

- Common UNIX™ system editors are **vi** and **ex**.
- If you use a text editor as the system default, you must save the `.sql` files as `text`.

Press **RETURN** to select the default editor you named after the USE-EDITOR prompt. To use a different editor, type the name of that editor and press **RETURN**.

Statements that the Run option supports

After you exit the editor screen, the SQL menu reopens with the Run option highlighted and the statement text is displayed in the bottom of the screen. You can run most SQL statements with the Run option.

To run statements that are not listed, use the SQL menu options New (or Use-editor) and Save to enter and save them, and then run the saved file from the command line.

The following is a list of SQL statements that you can run with the Run option.

- ALLOCATE COLLECTION
- ALLOCATE DESCRIPTOR
- ALLOCATE ROW
- ALTER ACCESS_METHOD
- ALTER FRAGMENT
- ALTER FUNCTION
- ALTER INDEX
- ALTER PROCEDURE
- ALTER ROUTINE
- ALTER SECURITY LABEL COMPONENT
- ALTER SEQUENCE
- ALTER TABLE
- BEGIN WORK
- CLOSE
- CLOSE DATABASE
- COMMIT WORK

- STOP VIOLATIONS TABLE
- TRUNCATE
- UNLOAD
- UNLOCK TABLE
- UPDATE
- UPDATE STATISTICS
- WHENEVER

For information about statements for Optical Subsystem, see the *Informix® Optical Subsystem Guide*.

Redirect query results

The output from a SELECT statement is normally displayed on the screen. You can use the Output option on the SQL menu to route query results to the printer, store them in a system file, or pipe them to a program. The Output option has the same result as the OUTPUT statement of SQL.

The SELECT statement must be on the screen as the current statement. Select the Output option from the SQL menu, which displays the OUTPUT menu.

You have the following output options:

- Send your query results directly to a printer. DB-Access sends the results to your default printer and displays a message on the bottom of the screen that indicates how many rows were retrieved. The query results do not show on the screen. You can set the **DBPRINT** environment variable to specify a default printer.
- Write query results to a new file or append the results to an existing file. If you do not specify a path when DB-Access prompts you for a file name, the file is stored in the directory that you were in when you started DB-Access.

- Send query results to a pipe. Specify a target program, such as **more**, through which to pipe output. DB-Access sends the results to that pipe.

On UNIX™ systems, you must have permission to run the target program.

On Windows™ systems, the cat utility can serve as a target program through which to pipe output.

Save the current SQL statement

You can save SQL statements in a file for later use, such as to run the statements from the command line or retrieve the saved statements with the Choose option on the SQL menu.

To save the current SQL statement or statements in a file, select the Save option on the SQL menu. Enter a name for the command file:

- Use 1 - 10 characters. Start with a letter, then use any combination of letters, numbers, and underscores (_). Press **Enter** to save the file.
- UNIX™: File names are case-sensitive. The file `orders` is not the same as `Orders` or `ORDERS`.

DB-Access appends the extension `.sql` to the file name. For example, if you name your file `cust1`, DB-Access stores the file with the name `cust1.sql`. The CHOOSE screen still lists `cust1`, but the operating system identifies the same file as `cust1.sql` if you list the directory files from the command line.

What happens when errors occur

If you make any syntax or typing mistakes in an SQL statement, DB-Access does not process the statement. Instead, it continues to display the text of the statement with a message that describes the error.

If an execution or runtime error occurs, DB-Access continues to process the statement and returns an error message. For example, if you try to create a table that was already created, the following message is displayed at the bottom of the screen:

```
310: Table (mavis.mystock) already exists in database.
```

If you try to run a statement that contains more than one SQL statement, you might not see an error message immediately. If, for example, the first statement is a SELECT statement that runs correctly and the next statement contains a typing error, the data that the first statement retrieved shows on the screen before the error message is displayed for the second statement.

When DB-Access detects an error, processing stops and the Modify option on the SQL menu is highlighted. Select one of the following methods to correct the statement:

- Press **Enter** to choose Modify, which returns you to the SQL editor.
- Select the Use-editor option to use the default editor of your choice.

The Database option

Use the Database option to work with databases and transactions.

Use the Database option to:

- Create a database or select a database.
 - The database that you work with is called the *current* database.
- Retrieve and display information about a database, such as available dbspaces and the text of routines.
- Delete an existing database or close the current database.
- Commit or rollback transactions.

You can access only databases that are on the current database server. To select a database server as current, you can specify a database server when you start DB-Access, you can use the Connection menu, or you can run a CONNECT statement from the SQL menu. If you do not explicitly select a database server, DB-Access uses the default database server that the **\$INFORMIXSERVER** environment variable specifies as the current database.

If you select or create a database when another database is already open, DB-Access closes that database before it makes your selection the current or new database.

The DATABASE menu displays the following options.

Option	Purpose
Select	Makes a database the current database
Create	Builds a new database and makes that database the current database
Info	Displays information about the current database
Drop	Removes a database from the system. You cannot delete the current database.
cLose	Closes the current database
Exit	Exits the DATABASE menu and returns you to the main menu

List of available databases

When you choose the Select option, the SELECT DATABASE screen opens. The first database in the list of available databases is highlighted, accompanied by the names of database servers.

The list is organized alphabetically by database server and then by database for each database server. You can display a maximum of 512 database names on the SELECT DATABASE screen.

 **Important:** In the SELECT DATABASE screen, the names of databases are limited to 18 characters. If a database name is longer than 18 characters, you see the first 17 characters of the name followed by a '+' sign. Enter a '+' sign to display the complete long name in **vi**. To exit from **vi**, press `ESC ZZ`.

The list of available databases that is displayed depends on two factors:

- The settings of certain environment variables.
 - If you use one database server, DB-Access displays the names of all databases on the current database server and in your **DBPATH** setting.
 - If you use multiple database servers, the **ONCONFIG** environment variable determines the current database server.
- The current connection. For example:
 - If no explicit connection exists, DB-Access displays the databases in the **DBPATH** setting.
 - If a current explicit connection exists, all databases in the **DBPATH** setting that pertain to the current database server are displayed.

Close a database

To close the current database, use the **cLose** option from the DATABASE menu.

If you begin a transaction but do not commit it or roll it back, and then you try to close a database with transactions, the TRANSACTION menu opens. The TRANSACTION menu ensures that you either commit or roll back an active transaction before you close the current database.

 **Important:** Select an option carefully. You might commit transactions that you do not want if you select Commit, and you do lose any new transactions if you select Rollback.

The TRANSACTION menu also opens whenever you attempt to open a new database or try to leave the DB-Access menu system without first terminating a transaction.

 **Important:** If you begin a transaction in an ANSI-compliant database but do not issue a COMMIT statement or ROLLBACK statement, then try to close the database using a non-menu mode, DB-Access commits the transaction for you. If you do not want to commit the transaction, issue both a ROLLBACK statement and a CLOSE DATABASE statement from the command line.

The Table option

Use the Table option to work with tables.

Use the Table option to perform any of the following table management tasks without SQL programming:

- Create a new table
- Define fragmentation strategy for a new or existing table
- Alter, delete, or display information about an existing table

Use the TABLE menu options as the following table shows.

Option	Purpose
Create	Enables you to define the structure of a new table. The CREATE TABLE menu provides data type options for built-in data types. To define a column with one of the extended data types, such as smart large objects, user-defined (opaque) data types, or a collection data type, use the SQL menu to enter and run a CREATE TABLE statement. DB-Access can construct only a nonclustered, ascending B-tree column index. If you want hash or hybrid fragmentation, use the SQL menu to enter and run the CREATE TABLE or ALTER TABLE statement.
Alter	<p>Enables you to alter the structure of an existing table, including columns, fragmentation, and constraints. You must have the Alter privilege to successfully alter a table.</p> <p> Note: If you use the UI to build the SQL statements to Alter a table without the Alter privilege, the table will be locked and the operation will fail. Further, the lock will be held until you exit the alter menu.</p> <p>To use the LOAD statement to insert data into a table, you must have both Insert and Select privileges for the table.</p>
Info	Displays information about the structure of a table
Drop	Deletes a table from the database
Move	Moves a table from the current database to another database.
Exit	Returns to the DB-Access main menu

Both the CREATE TABLE and ALTER TABLE menus have the same options, which are described in the following table.

Option	Purpose
Add	Displays the Schema Editor, from which you can add a new column to the table
Modify	Displays the columns that you defined with the Add option so that you can modify the column structure before building the table
Drop	Drops an existing column from the table
Screen	Displays the next screen of column definitions in the Schema Editor
Table_options	Enables you to display and select storage spaces for a new table. Displays choices from which to set a fragmentation strategy for a new table. Enables you

Option	Purpose
	to set extent sizes and lock mode for a new table. Adds or deletes rowids for an existing fragmented table.
Constraints	Enables you to define primary-key, foreign-key, check, and unique constraints, and to set default column values
Exit	Builds, rebuilds, or discards the schema and structure that you specified with the other options, and then returns to the TABLE menu

Important: You must use the **SPACEBAR** to move between menu options, because the arrow keys control cursor movement in the Schema Editor.

Display table information

Use the Info option on the TABLE menu to display information about the structure of a table.

Note the following items:

- If you are not the table owner, the table name is prefixed by the owner name, as in **june.clients**.
- If the list of tables does not fit on one screen, the last entry is an ellipsis (...). Use the arrow keys to highlight the ellipsis, and the next page of table names are displayed.
- If globalization is enabled, the list of table names is sorted according to the database collation rules defined when the database was created. Thus, different users using different collating sequences for DB-Access see the table names in the database listed in the same order.

To request information about tables on a different database server, use the format *database@server:table* or *database@server.owner.table* at the prompt. The following example requests information about the **customer** table that **dba** created in the **accounts** database on the database server **topend**:

```
INFO FOR TABLE >> accounts@topend:dba.customer
```

The INFO menu has the following options.

Option	Purpose
Columns	Lists data type by column name and indicates which columns can contain a null value
Indexes	Describes each index that is defined for a specified table
Privileges	Lists the users who have Select, Update, Insert, Delete, Index, or Alter privileges for the specified table
References	Lists the users who have the table-level References privilege for the specified table and the names of the columns they can reference

Option	Purpose
Status	Lists the table name, owner, row size, number of rows and columns, and creation date of the current table
cOnstraints	Displays the referential, primary, unique, and check constraints, and the default values for the columns in the specified table
triGgers	Displays header and body information for a specified trigger
Table	Redisplays the INFO FOR TABLE menu so that you can select a different table for examination
Fragments	Lists fragmented dbspaces assigned to the table and, for expression-based fragmentation, displays the expression that is assigned to each dbspace
Exit	Returns to the TABLE menu

 **Tip:** From the CREATE TABLE menu, use Table-options to view extent and lock mode information, or issue a SELECT statement to list the table description in the **systables** system catalog table.

The Connection and Session options

Use the Connection option if you want to connect to a specific database server and database or explicitly disconnect from the current database environment. Use the Session option to display information about the current DB-Access session.

For the globalization considerations that apply to establishing a connection between a client application, such as DB-Access, and a database, see the *Informix® GLS User's Guide*. The database server examines the client locale information passed by the client, verifies the database locale, and determines the server-processing locale for transferring data between the client and the database.

You can use the Secure Sockets Layer (SSL) protocol, a communication protocol that ensures privacy and integrity of data that is transmitted over the network, for DB-Access connections with HCL Informix®. For information about the SSL protocol, see [Secure sockets layer protocol on page](#).

On Windows™, if you specify a user identifier but no domain name for a connection to a machine that expects both a domain name and a user name (`domain\user`), DB-Access checks only the local machine and the primary domain for the user account. If you explicitly specify a domain name, that domain is used to search for the user account. The attempted connection fails with error -951 if no matching `domain\user` account is found on the local machine.

The CONNECTION menu displays the following options.

Option	Purpose
Connect	Connects to a database environment. To access a specific database, you must have permission.

Option	Purpose
Disconnect	Disconnects from the current database environment
Exit	Returns to the DB-Access main menu

When you use the Connect option, the SELECT DATABASE screen alphabetically lists all available databases on the specified database server. The database list on the SELECT DATABASE screen depends on the current connection. For example:

- If no current connection exists or the current connection is an implicit default connection, all the databases that are listed in the **DBPATH** environment variable setting are displayed.
- If a current explicit connection exists, all the databases in the **DBPATH** that pertain to the current server are displayed.

Implicit closures

DB-Access closes any open connections or databases when you connect to a new environment.

DB-Access closes any open connections or databases in the following situations:

- When you connect to a new database environment without explicitly disconnecting from the current one, DB-Access performs an implicit disconnect and the database closes.
- When you connect to a *database@server* and then close the database, the database server remains connected.
- When you connect to a database server, open a database, and then close the database, the database server remains connected.
- If you open a database and then try to connect to a database server, DB-Access performs an implicit disconnect and closes the database.

Only one connection is allowed. You must disconnect from the database server associated with the open database or close the database before you can connect to another database server.

If DB-Access must close a database that still has outstanding transactions, it prompts you to commit or roll back those transactions.

Appendixes

How to read online help for SQL statements

Specific conventions are used to represent the syntax of SQL statements in DB-Access online help screens.

You can request online help for SQL statements in either of the following ways:

- Highlight the New, Modify, or Use-editor options on the SQL menu and press **CTRL-W**.
- Press **CTRL-W** while you are on the NEW or MODIFY screens of the SQL menu.

The form of the syntax diagrams that shows when you request online Help for SQL statements in DB-Access is different from the syntax diagrams in the *Informix® Guide to SQL: Syntax*.

The conventions and rules governing SQL statement syntax in DB-Access online help screens are described in the following list.

ABC

Any term in an SQL statement that is displayed in uppercase letters is a keyword. Type keywords exactly, disregarding case, as shown in the following example:

```
CREATE SYNONYM synonym-name
```

This syntax indicates you must type the keywords CREATE SYNONYM or create synonym without adding or deleting spaces or letters.

abc

Substitute a value for any term that is displayed in lowercase letters. In the previous example, substitute a value for synonym-name.

()

Type any parentheses as shown. They are part of the syntax of an SQL statement and are not special symbols.

[]

Do not type brackets as part of a statement. They surround any part of a statement that is optional. For example:

```
CREATE [TEMP] TABLE
```

This syntax indicates that you can type either CREATE TABLE or CREATE TEMP TABLE.

|

The vertical bar indicates a choice among several options. For example:

```
[VANILLA | CHOCOLATE [MINT] | STRAWBERRY]
```

This syntax indicates that you can enter either VANILLA, CHOCOLATE, or STRAWBERRY and that, if you enter CHOCOLATE, you can also enter MINT.

{}

When you must choose only one of several options, the options are enclosed in braces and are separated by vertical bars. For example:

```
{GUAVA | MANGO | PASSIONFRUIT}
```

This syntax indicates that you must enter either GUAVA, MANGO, or PASSIONFRUIT, but you cannot enter more than one choice.

...

An ellipsis indicates that you can enter an indefinite number of additional items, such as the one immediately preceding the ellipsis. For example:

```
old-column-name  
...
```

This syntax indicates that you can enter a series of existing column names after the first one.

The *Informix® Guide to SQL: Syntax* contains more detailed syntax diagrams and instructions for interpreting the diagram format that is used in the publication.
