| Element                 | Description   | Restrictions   | Syntax                                     |
|-------------------------|---|--|--|
| <i>field_delimiter</i>  | Character to separate fields. Default is pipe ( ) character | If you do not set the <b>RECORDEND</b> environment variable, the default value for <i>record_delimiter</i> is the newline character (CTRL-J).<br><br>If you use a non-printing character as a delimiter, encode it as the octal representation of the ASCII character. For example, '\006' can represent CTRL-F. | <a href="#">Quoted String on page 1424</a> |
| <i>record_delimiter</i> | Character to separate records                               |  | <a href="#">Quoted String on page 1424</a> |
| <i>table</i>            | Name declared here of a table to receive the query results  | Must be unique among names of tables, views, synonyms, and sequence objects that you own in the current database   | <a href="#">Identifier on page 1456</a>    |

The INTO EXTERNAL clause combines the functionality of the CREATE EXTERNAL TABLE . . . SAMEAS and INSERT INTO . . . SELECT statements.

The INTO EXTERNAL clause overwrites any previously existing rows in the external table. Use the Table Options clause of the INTO EXTERNAL clause to specify the format of the unloaded data in the external table.

434. Use this path no more than once

435. See [DATAFILES Clause on page 216](#)

In the `SELECT ... INTO EXTERNAL` statement, you can specify all table options that are discussed in the `CREATE EXTERNAL TABLE` statement except the fixed-format option.

You can use the `INTO EXTERNAL` clause when the format type of the created data file is either delimited text (if you use the `DELIMITED` keyword) or text in Informix® internal data format (if you use the `INFORMIX` keyword). You cannot use it for a fixed-format unload.

You use the following keywords to unload data. If you want to specify additional table options in the external-table description for reloading the table later, see [Table options on page 218](#).

#### **DELIMITER**

Specifies the character that separates fields in a delimited text file

#### **ESCAPE**

Directs the database server to recognize ASCII special characters embedded as separators between fields in ASCII-text-based data files Inserts the default escape character immediately before any instances of the *field\_delimiter* separator that `DELIMITER` specifies, where that character is a literal value in the data, rather than a separator. Whether you include or omit the `ESCAPE` keyword, this functionality is enabled by default, or you can specify the `ESCAPE ON` keywords to make it clearer to human readers of your SQL code that this feature is enabled. To prevent literal *field\_delimiter* separator characters in the data from being escaped, you must specify the `ESCAPE OFF` keywords.

By default, the escape character that the `ESCAPE` keyword inserts before literal *field\_delimiter* characters is the backslash ( `\` ) character. But if the `DEFAULTESCCHAR` configuration parameter is set to a single-character value, that character replaces backslash ( `\` ) for delimiter characters used as literals when `ESCAPE OR` `ESCAPE ON` is specified.

#### **Important:**

The default setting for `ESCAPE` is `OFF` in Informix® releases earlier than version 12.10.

#### **FORMAT**

Specifies the format of the data in the data files

#### **RECORDEND**

Specifies the character that separates records in a delimited text file

For more information about external tables, see the [CREATE EXTERNAL TABLE Statement on page 213](#).

## **SET AUTOFREE statement**

Use the `SET AUTOFREE` statement to instruct the database server to enable or disable a memory-management feature that can free the memory allocated for a cursor automatically, as soon as the cursor is closed.

**Syntax****SET AUTOFREE****ENABLED****DISABLED****FOR***cursor\_id cursor\_id\_var*

| Element              | Description  | Restrictions  | Syntax   |
|----------------------|--|---|--|
| <i>cursor_id</i>     | Name of a cursor for which Autofree is to be reset     | Must already be declared within the program                   | <a href="#">Identifier on page 1456</a>            |
| <i>cursor_id_var</i> | Host variable that holds the value of <i>cursor_id</i> | Must store a <i>cursor_id</i> already declared in the program | Must conform to language-specific rules for names. |

**Usage**

This statement is an extension to the ANSI/ISO standard for SQL. You can use this statement only with Informix® ESQL/C.

When the Autofree feature is enabled for a cursor, and the cursor is subsequently closed, you do not need to explicitly use the FREE statement to release the memory that the database server allocated for the cursor. If you issue SET AUTOFREE but specify no option, the default is ENABLED.

The SET AUTOFREE statement that enables the Autofree feature must appear before the OPEN statement that opens a cursor. The SET AUTOFREE statement does not affect the memory allocated to a cursor that is already open. After a cursor is Autofree enabled, you cannot open that cursor a second time.

**Related reference**[CLOSE statement on page 179](#)[DECLARE statement on page 467](#)[FETCH statement on page 561](#)[FREE statement on page 574](#)[OPEN statement on page 677](#)[PREPARE statement on page 687](#)**Globally Affecting Cursors with SET AUTOFREE**

If you include no FOR *cursor\_id* or FOR *cursor\_id\_var* clause, then the scope of SET AUTOFREE is all subsequently-declared cursors in the program (or more precisely, all cursors declared before a subsequent SET AUTOFREE statement with no FOR clause globally resets the Autofree feature). This example enables the Autofree feature for all subsequent cursors in the program:

```
EXEC SQL set autofree;
```

The next example disables the Autofree feature for all subsequent cursors:

```
EXEC SQL set autofree disabled;
```

## Using the FOR Clause to Specify a Specific Cursor

If you specify `FOR cursor_id` or `FOR cursor_id_var`, then `SET AUTOFREE` affects only the cursor that you specify after the `FOR` keyword.

This option allows you to override a global setting for all cursors. For example, if you issue a `SET AUTOFREE ENABLED` statement for all cursors in a program, you can issue a subsequent `SET AUTOFREE DISABLED FOR` statement to disable the Autofree feature for a specific cursor.

In the following example, the first statement enables the Autofree feature for all cursors, while the second statement disables the Autofree feature for the cursor named `x1`:

```
EXEC SQL set autofree enabled;
EXEC SQL set autofree disabled for x1;
```

Here the `x1` cursor must have been declared but not yet opened.

## Associated and Detached Statements

When a cursor is automatically freed, its associated prepared statement (or associated statement) is also freed.

The term *associated statement* has a special meaning in the context of the Autofree feature. A cursor is associated with a prepared statement if it is the first cursor that you declare with the prepared statement, or if it is the first cursor that you declare with the statement after the statement is detached.

The term *detached statement* has a special meaning in the context of the Autofree feature. A prepared statement is detached if you do not declare a cursor with the statement, or if the cursor with which the statement is associated was freed.

If the Autofree feature is enabled for a cursor that has an associated prepared statement, and that cursor is closed, the database server frees the memory allocated to the prepared statement as well as the memory allocated for the cursor.

Suppose that you enable the Autofree feature for the following cursor:

```
/*Cursor associated with a prepared statement */
EXEC SQL prepare sel_stmt 'select * from customer';
EXEC SQL declare sel_curs2 cursor for sel_stmt;
```

When the database server closes the `sel_curs2` cursor, it automatically performs the equivalent of the following `FREE` statements:

```
FREE sel_curs2;
FREE sel_stmt;
```

Because memory for the `sel_stmt` statement is freed automatically, you cannot declare a new cursor on it unless you prepare the statement again.

## Closing Cursors Implicitly

A potential problem exists with cursors that have the Autofree feature enabled. In a database that is not ANSI-compliant, if you do not close a cursor explicitly and then open it again, the cursor is closed implicitly. This implicit closing of the cursor

triggers the Autofree feature. The second time the cursor is opened, the database server generates an error message (`cursor not found`) because the cursor is already freed.

## SET COLLATION statement

Use the SET COLLATION statement to specify a new collating order for the session, superseding the collation implied by the DB\_LOCALE environment variable setting. SET NO COLLATION restores the default collation.

### Syntax

#### SET

**COLLATION***locale*

**NO COLLATION**

| Element       | Description  | Restrictions   | Syntax                                     |
|---------------|--|--|--|
| <i>locale</i> | Name of a locale whose collating order is to be used in this session | Must be the name of a locale that the database server can access | <a href="#">Quoted String on page 1424</a> |

### Usage

The SET COLLATION statement is an extension to the ANSI/ISO standard for SQL. You can use this statement with Informix® ESQL/C.

As the *Informix® GLS User's Guide* explains, the database server uses locale files to specify the character set, the collating order, and other conventions of some natural language to display and manipulate character strings and other data values. The collating order of the database locale is the sequential order in which the database server sorts character strings.

If you set no value for DB\_LOCALE, the default locale, based on United States English, is **en\_us.8859-1** for UNIX™, or Code Page 1252 for Windows™ systems. Otherwise, the database server uses the DB\_LOCALE setting as its locale. The SET COLLATION statement overrides the collating order of DB\_LOCALE at runtime for all database servers previously accessed in the same session.

The new collating order remains in effect for the rest of the session, or until you issue another SET COLLATION statement. Other sessions are not affected, but database objects that you created with a non-default collation use whatever collating order was in effect at their time of their creation.

By default, the collating order is the code-set order, but some locales also support a locale-specific order. In most contexts, only NCHAR and NVARCHAR data values can be sorted according to a locale-specific collating order.

## Specifying a Collating Order with SET COLLATION

SET COLLATION replaces the current collating order for NCHAR and NVARCHAR values with that of the specified *locale* for all database servers previously accessed in the current session.

For example, this statement specifies the collating order for the **GB18030-2000** code set of the Chinese language:

```
EXEC SQL set collation "zh_cn.gb18030-2000";
```

If the next operation of a database server in this session sorted NCHAR or NVARCHAR values, the result would follow the Chinese collating order that the SET COLLATION statement specified.

Suppose that in the same session, the following SET NO COLLATION statement restores the **DB\_LOCALE** setting for the collating order:

```
EXEC SQL set no collation;
```

After SET NO COLLATION executes, subsequent collation in the same session is based on the **DB\_LOCALE** setting. Any database objects that you created using the Chinese collating order, however, such as check constraints, indexes, prepared objects, triggers, or UDRs, will continue to apply Chinese collation rules to NCHAR and NVARCHAR data types.

### Collation in an NLSCASE INSENSITIVE database

Suppose that you use the following SET COLLATION statement to replace the current collating order with that of the **de\_de.8859-1** locale for the German language:

```
SET COLLATION "de_de.8859-1";
```

By default, this locale supports case differences between uppercase and lowercase alphabetic characters. For example, two CHAR or NVARCHAR strings of the same letters and in the same order, but with differences in case, such as 'Zug' and 'ZUG', are treated in LIKE or MATCHES expressions or sorted in ORDER BY clauses as distinct data values.

In a database created with the `NLSCASE INSENSITIVE` keywords, however, collating operations on NCHAR and NVARCHAR data disregard case differences, so that the database server treats case variants among strings composed of same sequence letters as duplicates. The resulting collated list orders these case-insensitive duplicates in their order of retrieval, so a collated list with case variants of the string `alpha` might appear in any order, such as this order, which disregards variations in case:

```
aLpha
ALpha
aLpha
ALPHA
ALpha
```

For more information, see [Duplicate rows in NLSCASE INSENSITIVE databases on page 779](#) and [NCHAR and NVARCHAR expressions in case-insensitive databases on page 1174](#).

## Restrictions on SET COLLATION

Although SET COLLATION enables you to change the collating order of the database server dynamically within a session, you should be aware of several limitations on the scope of what the SET COLLATION statement can accomplish.

- Only collation performed by the database server is affected. Client processes that sort data are not affected by SET COLLATION.
- Only the current session is affected. Other sessions are not affected directly by your SET COLLATION statements, but the database server will use their creation-time collating order to set any database objects that you create after SET COLLATION has run successfully.

- Changing the collating order does not change the code set. The database server always uses the code set specified by **DB\_LOCALE**.
- Only NCHAR and NVARCHAR values are sorted in locale-specific order.

### Processing characters from dissimilar code sets

Because SET COLLATION changes only the collating order, rather than the current locale or code set, you generally cannot use this statement to insert character data from different locales into the same database. You must instead use a locale that supports Unicode if the database needs to store characters from two or more languages that require inherently different code sets or code pages. For Informix® ESQL/C applications and for other client applications that use the HCL Informix® GLS library, databases with locales that support UTF-8 character encoding can store characters that correspond to code points from dissimilar character sets of more than one natural language, but only if all of the following conditions are satisfied:

- The **GL\_USEGLU** environment variable was set to `1` when the database server instance was started.
- The **DB\_LOCALE** environment variable was set to a valid Unicode locale when the database was created.
- The **CLIENT\_LOCALE** environment variable is set to valid Unicode locale that the **DB\_LOCALE** setting of the database server supports.

For HCL Informix® to use the International Components for Unicode (ICU) 4.8.1 libraries to support versions of Unicode up to 6.0, the **GL\_USEGLU** environment variable must be set to a value of `1` (one) in the server environment before the server is started. This setting initializes conversion routines that enable Unicode collation and SQL operations in databases that use **UTF-8** character encoding, including the Chinese **GB18030-2000** code set. This conversion applies only to databases that were created with `GL_USEGLU=1` already set.

**Attention:** The **GL\_USEGLU** environment variable has no effect, however, on JDBC client applications, including those of the HCL Informix® JSON compatibility wire protocol listener. To support JDBC applications correctly in Unicode locales, there is no requirement that **GL\_USEGLU** be set to `1` in the client or in the server environments.

## Collation Performed by Database Objects

Although the database reverts to the **DB\_LOCALE** collating order after the session ends (or after you execute SET NO COLLATION), objects that you create using a non-default collation persist in the database. You can create, for example, multiple indexes on the same set of columns, called *multilingual indexes*, using different collating orders that SET COLLATION specifies.

Only one clustered index, however, can exist on a given set of columns.

Only one unique constraint or primary key can exist on a given set of columns, but you can create multiple unique indexes on the same set of columns, if each index has a different collation order.

The query optimizer ignores indexes that apply any collation other than the current session collation to NCHAR or NVARCHAR columns when calculating the cost of a query.

The collating order of an attached index must be the same as that of its table, and this must be the default collating order specified by **DB\_LOCALE**.

The ALTER INDEX statement cannot change the collation of an index. Any previous SET COLLATION statement is ignored when ALTER INDEX executes.

When you compare values from CHAR columns with NCHAR columns, Informix® casts the CHAR value to NCHAR, and then applies the current collation. Similarly, before comparing VARCHAR and NVARCHAR values, Informix® first casts the VARCHAR values to NVARCHAR.

When synonyms are created for remote tables or views, the participating databases must have the same collating order. Existing synonyms, however, can be used in other databases that support SET COLLATION and the collating order of the synonym, regardless of the **DB\_LOCALE** setting.

Check constraints, cursors, prepared objects, triggers, and SPL routines that sort NCHAR or NVARCHAR values use the collation that was in effect at the time of their creation, if this is different from the **DB\_LOCALE** setting.

The effect on performance is sensitive to how many different collations are used when creating database objects that sort in a localized order.

## SET CONNECTION statement

Use the SET CONNECTION statement to reestablish a connection between an application and a database environment and to make the connection current. You can also use this statement with the DORMANT option to put the current connection in a dormant state. Use this statement with Informix® ESQL/C.

### Syntax

#### SET CONNECTION

*'connection '*

<sup>436</sup>*connection\_var*

<sup>436</sup>

Database Environment<sup>437</sup>

#### DEFAULT

<sup>436</sup> **DORMANT**

<sup>436</sup> **CURRENT DORMANT**

| Element               | Description  | Restrictions                    | Syntax                                     |
|-----------------------|--|---------------------------------|--|
| <i>connection</i>     | Name of the initial connection that the CONNECT statement made | The database must already exist | <a href="#">Quoted String on page 1424</a> |
| <i>connection_var</i> | Host variable that contains the value of <i>connection</i>     | Must be a character data type   | Language specific                          |

436. Informix® extension

437. See [Database Environment on page 187](#)

## Usage

You can use SET CONNECTION to make a dormant connection the current connection or to make the current connection dormant.

SET CONNECTION is not valid as a prepared statement.

---

[CONNECT statement on page 185](#)

[DATABASE statement on page 461](#)

## Making a dormant connection as the current connection

If you use the SET CONNECTION statement without the DORMANT option, *connection* must represent a dormant connection. A *dormant connection* is a connection that is established but is not current.

The SET CONNECTION statement, with no DORMANT option, makes the specified dormant connection the current one. The connection that the application specifies must be dormant. The connection that is current when the statement executes becomes dormant.

The SET CONNECTION statement in the following example makes connection `con1` the current connection and makes `con2` a dormant connection:

```
CONNECT TO 'stores_demo' AS 'con1';
...
CONNECT TO 'demo' AS 'con2';
...
SET CONNECTION 'con1';
```

A dormant connection has a *connection context* associated with it. When an application makes a dormant connection current, it reestablishes that connection to a database environment and restores its connection context. (For more information on connection context, see the [CONNECT statement on page 185](#) statement on page [CONNECT statement on page 185](#).) Reestablishing a connection is comparable to establishing the initial connection, except that it typically avoids authenticating the permissions for the user again, and it avoids reallocating resources associated with the initial connection. For example, the application does not need to reprepare any statements that have previously been prepared in the connection, nor does it need to redeclare any cursors.

## Making a current connection as the dormant connection

In the SET CONNECTION *connection* DORMANT statement, *connection* must represent the current connection. The SET CONNECTION statement with the DORMANT option makes the specified current connection a dormant connection.

For example, the following SET CONNECTION statement makes connection `con1` dormant:

```
SET CONNECTION 'con1' DORMANT;
```

The SET CONNECTION statement with the DORMANT option generates an error if you specify a connection that is already dormant. For example, if connection `con1` is current and connection `con2` is dormant, the following SET CONNECTION statement returns an error message:

```
SET CONNECTION 'con2' DORMANT;
```

The following SET CONNECTION statement executes successfully:

```
SET CONNECTION 'con1' DORMANT;
```

## Dormant Connections in a Single-Threaded Environment

In a single-threaded Informix® ESQL/C application (one that does not use threads), the DORMANT option makes the current connection dormant. Using this option makes single-threaded Informix® ESQL/C applications upwardly compatible with thread-safe Informix® ESQL/C applications. A single-threaded environment, however, can have only one active connection while the program executes.

## Dormant Connections in a Thread-Safe Environment

In a thread-safe Informix® ESQL/C application, the DORMANT option makes an active connection dormant. Another thread can now use the connection by issuing the SET CONNECTION statement without the DORMANT option. A thread-safe environment can have many threads (concurrent pieces of work performing particular tasks) in one Informix® ESQL/C application, and each thread can have one active connection.

An active connection is associated with a particular thread. Two threads cannot share the same active connection. Once a thread makes an active connection dormant, that connection is available to other threads. A dormant connection is still established but is not currently associated with any thread. For example, if the connection named `con1` is active in the thread named `thread_1`, the thread named `thread_2` cannot make connection `con1` its active connection until `thread_1` has made connection `con1` dormant.

The following code fragment from a thread-safe Informix® ESQL/C program shows how a particular thread within a thread-safe application makes a connection active, performs work on a table through this connection, and then makes the connection dormant so that other threads can use the connection:

```
thread_2()
{ /* Make con2 an active connection */
  EXEC SQL connect to 'db2' as 'con2';
  /*Do insert on table t2 in db2*/
  EXEC SQL insert into table t2 values(10);
  /* make con2 available to other threads */
  EXEC SQL set connection 'con2' dormant;
}
```

If a connection to a database environment was initiated using the CONNECT . . . WITH CONCURRENT TRANSACTION statement, any thread that subsequently connects to that database environment can use an ongoing transaction. In addition, if an open cursor is associated with such a connection, the cursor remains open when the connection is made dormant.

Threads within a thread-safe Informix® ESQL/C application can use the same cursor by making the associated connection current, even though only one thread can use the connection at any given time.

## Identifying the Connection

If the application did not specify a connection name in the initial `CONNECT` statement, you must use a database environment (such as a database name or a database pathname) as the connection name. For example, the following `SET CONNECTION` statement uses a database environment for the connection name because the `CONNECT` statement does not use a connection name. For information about quoted strings that specify a database environment, see [Database Environment on page 187](#).

```
CONNECT TO 'stores_demo';  
...  
CONNECT TO 'demo';  
...  
SET CONNECTION 'stores_demo';
```

If a connection to a database server was assigned a connection name, however, you must use the connection name to reconnect to the database server. An error is returned if you use a database environment rather than the connection name when a connection name exists.

## DEFAULT Option

The `DEFAULT` option specifies the default connection for a `SET CONNECTION` statement. The default connection is one of the following connections:

- An explicit default connection (a connection established with the `CONNECT TO DEFAULT` statement)
- An implicit default connection (any connection established with the `DATABASE` or `CREATE DATABASE` statements)

Use `SET CONNECTION` without a `DORMANT` option to reestablish the default connection, or with that option to make the default connection dormant.

For more information, see [The DEFAULT Connection Specification on page 191](#) and [The Implicit Connection with DATABASE Statements on page 191](#).

## CURRENT Keyword

Use the `CURRENT` keyword with the `DORMANT` option of the `SET CONNECTION` statement as a shorthand form of identifying the current connection. The `CURRENT` keyword replaces the current connection name. If the current connection is `con1`, the following two statements are equivalent:

```
SET CONNECTION 'con1' DORMANT;  
  
SET CONNECTION CURRENT DORMANT;
```

## When a Transaction is Active

Without the DORMANT keyword, the SET CONNECTION statement implicitly puts the current connection in the dormant state.

When you issue a SET CONNECTION statement with the DORMANT keyword, the SET CONNECTION statement explicitly puts the current connection in the dormant state. In both cases, the statement can fail if a connection that becomes dormant has an uncommitted transaction. If the connection that becomes dormant has an uncommitted transaction, the following conditions apply:

- If the connection was established using the WITH CONCURRENT TRANSACTION clause of the CONNECT statement, SET CONNECTION succeeds and puts the connection in a dormant state.
- If the connection was not established by the WITH CONCURRENT TRANSACTION clause of the CONNECT statement, SET CONNECTION fails and cannot set the connection to a dormant state, and the transaction in the current connection continues to be active. The statement generates an error and the application must decide whether to commit or roll back the active transaction.

## SET CONSTRAINTS statement

Use the SET CONSTRAINTS statements to change how some or all of the existing constraints on a table are processed.

### Syntax

Only the CREATE TABLE, CREATE TEMP TABLE and ALTER TABLE ADD CONSTRAINT statements of SQL can create new constraints. The SET CONSTRAINTS statement supports the following syntax for modifying how the database server enforces (or ignores) one or more existing constraints on a single table:

**SET CONSTRAINTS***, constraint***ALL****IMMEDIATE DEFERRED**

438

*, constraint***FOR***'owner' .**table*

Constraint Mode

Constraint Mode

**DISABLED****ENABLED****FILTERING****WITHOUT ERROR WITH ERROR**

439

440 **NOVALIDATE**

| Element           | Description  | Restrictions  | Syntax                                  |
|-------------------|--|---|---|
| <i>constraint</i> | Constraint whose mode is to be reset                           | Must exist, and must all be defined on the same table | <a href="#">Identifier on page 1456</a> |
| <i>owner</i>      | Owner of <i>table</i>  | Must own table  | <a href="#">Owner name on page 1488</a> |
| <i>table</i>      | Table whose constraint mode is to be reset for all constraints | Must exist in the database                            | <a href="#">Identifier on page 1456</a> |

**Usage**

Constraint-mode keyword options of the SET CONSTRAINTS statements include these:

- Whether constraints are checked at the statement level (`IMMEDIATE`) or at the transaction level (`DEFERRED`)
- Whether to enable (`ENABLED`) or disable (`DISABLED`) constraints
- Whether the filtering mode of constraints on tables with violations tables should be `FILTERING WITH ERROR` or `FILTERING WITHOUT ERROR`
- Whether to enable referential constraints without verifying (`NOVALIDATE`) that the foreign-key value in every row matches a primary-key value in the referenced table.
- Whether to enable check constraints without verifying (`NOVALIDATE`) that the value in every row satisfies the specified conditions.

438. Informix® extension. Constraint must be on a table in the current database.

439. See [Filtering Modes on page 881](#)

440. Valid for FOREIGN KEY or CHECK constraints only

The `SET CONSTRAINTS` keywords can begin the SET Transaction Mode statement, which is described in [SET Transaction Mode statement on page 1007](#).

The `SET CONSTRAINTS` keywords can also begin a special case of the SET Database Object Mode statement, which is an extension to the ANSI/ISO standard for SQL. Besides constraints, the SET Database Object Mode statement can also enable or disable a trigger or index, or change the filtering mode of a unique index. For the complete syntax and semantics of that statement, see [SET Database Object Mode statement on page 871](#).

For information on using the SET CONSTRAINTS statement to enable or disable system-defined indexes that are implicitly created by PRIMARY KEY and FOREIGN KEY constraint definitions, see the topic [SET INDEXES statement on page 973](#).

## Persistence of Constraint Modes

Any changes that you make to the mode of a constraint persist until that constraint mode setting is modified again, or until that constraint or its table are dropped.

The NOVALIDATE modes, however, are exceptions, because these mode do not persist beyond the SET CONSTRAINTS statement (or beyond the ALTER TABLE ADD CONSTRAINT statement) that specified the NOVALIDATE mode.

For example, for foreign-key constraints, when the DDL statement that specifies a NOVALIDATE mode completes, the constraint mode reverts to whichever mode the **sysobjstate** system catalog table recorded for that foreign-key constraint among these three possible modes:

- `ENABLED NOVALIDATE` becomes `ENABLED`
- `FILTERING WITH ERROR NOVALIDATE` becomes `FILTERING WITH ERROR`
- `FILTERING WITHOUT ERROR NOVALIDATE` becomes `FILTERING WITHOUT ERROR`.

In all subsequent DML operations on the table, such as DELETE, INSERT, MERGE, or UPDATE statements of SQL, the database server enforces the enabled foreign-key constraint at a time determined by its `IMMEDIATE` or `DEFERRED` setting, but ignoring any previous `NOVALIDATE` mode.

## Restrictions on Secondary Servers

In cluster environments, the SET CONSTRAINTS ENABLED and SET CONSTRAINTS DISABLED statements are not supported on updatable secondary servers. (More generally, session-level index, trigger, and constraint modes that the SET Database Object Mode statement specifies are not redirected for UPDATE operations on table objects in databases of secondary servers.)

---

[SET Transaction Mode statement on page 1007](#)

[SET Database Object Mode statement on page 871](#)

[SET INDEXES statement on page 973](#)

## SET Database Object Mode statement

Use the SET Database Object Mode statement to change the filtering mode of constraints and of unique indexes, or to enable or disable constraints, indexes, and triggers, or to bypass referential-integrity checking of constraints while this statement is resetting the constraint mode.

This statement is an extension to the ANSI/ISO standard for SQL. To specify whether constraints are checked at the statement level or at the transaction level, see [SET Transaction Mode statement on page 1007](#).

### Syntax

#### SET

Object-List Format<sup>441</sup>

Table Format<sup>442</sup>

### Usage

In the context of this statement, *database object* has the restricted meaning of an *index*, a *trigger*, or a *constraint*, rather than the more general meaning of this term that the description of the [Database Object Name on page 1450](#) segment defines in [Other syntax segments on page 1433](#).

The scope of the SET Database Object Mode statement is restricted to constraints, indexes, or triggers in the local database to which the session is currently connected. After you change the mode of an object, the new mode is in effect for all sessions of that database, and persists until another SET Database Object Mode statement changes it again, or until the object is dropped from the database.

#### Important:

The NOVALIDATE modes to which this statement can reset foreign-key constraints are exceptions to the general statement above, as the following section of this topic explains.

### Object modes for triggers, indexes and constraints

Only two object modes are available for triggers and for indexes that allow duplicate values:

- Enabled (specified by the `ENABLED` keyword)
- Disabled (specified by the `DISABLED` keyword)

For constraints and for unique indexes, you can also specify two additional modes:

- filtering without integrity-violation errors (by the `FILTERING WITHOUT ERROR` keywords)
- filtering with integrity-violation errors (by the `FILTERING WITH ERROR` keywords)

For foreign-key and check constraints, you can also specify three additional modes:

441. See [Object-List Format on page 874](#)

442. See [Table Format on page 875](#)

- enabled, but without checking for integrity-violation errors (by the `ENABLED NOVALIDATE` keywords)
- filtering with integrity-violation errors, but without checking for integrity-violation errors (by the `FILTERING WITH ERROR NOVALIDATE` keywords)
- filtering without integrity-violation errors, but without checking for integrity-violation errors (by the `FILTERING WITHOUT ERROR NOVALIDATE` keywords).

The constraint modes with the `NOVALIDATE` keyword only persist while the `SET Database Object Mode` statement is running, after which the constraint mode reverts to the corresponding enabled or filtering mode, and with enforcement of referential integrity or check conditions during subsequent DML operations. But for large tables that are thought to be free of referential or check constraint violations, these modes that bypass validation of the foreign-key or check constraint can significantly reduce the time required to migrate or to import large data sets.

At any given time, an object must be in exactly one of these modes. These modes, which are sometimes called *object states*, are described in the section [Definitions of Database Object Modes on page 880](#).

The `sysobjstate` system catalog table lists all of the constraint, index, and trigger objects in the database, and the current mode of each object. Because the `NOVALIDATE` modes persist only during the `SET CONSTRAINTS` statement or `ALTER TABLE ADD CONSTRAINT` statement that specified that mode, the `sysobjstate` table ignores `NOVALIDATE` modes, which suppress violation-checking only within those DDL statements. For information on the `sysobjstate` table, see the *Informix® Guide to SQL: Reference*.

In cluster environments, the `SET Database Object Mode` statement is not supported on updatable secondary servers. (More generally, any session-level index, trigger, or constraint modes that the statement specifies are not redirected for `UPDATE` operations on table objects in databases of secondary servers.)

## Privileges Required for Changing Database Object Modes

To change the mode of a constraint, index, or trigger, you must have the necessary access privileges. You must meet at least one of these requirements:

- You must have the DBA privilege on the database.
- You must be the owner of the table on which the database object is defined and you must also have the Resource privilege on the database.
- You must have the Alter privilege on the table on which the database object is defined and you must also have the Resource privilege on the database.

## Object-List Format

Use the object-list format to change the mode for one or more constraint, index, or trigger.

Object-List Format

### CONSTRAINTS

, *constraint*

Modes for Constraints and Unique Indexes <sup>443</sup>

### INDEXES

, *index*

Modes for Constraints and Unique Indexes <sup>443</sup>

Modes for Triggers and Duplicate Indexes <sup>444</sup>

### TRIGGERS

, *trigger*

Modes for Triggers and Duplicate Indexes <sup>444</sup>

| Element           | Description                                  | Restrictions  | Syntax                                  |
|-------------------|--|---|---|
| <i>constraint</i> | Name of a constraint whose mode is to be set | Must be a local constraint, and all constraints in the list must be defined on the same table   | <a href="#">Identifier on page 1456</a> |
| <i>index</i>      | Name of an index whose mode is to be set     | Must be a local index, and all indexes in the list must be defined on the same table            | <a href="#">Identifier on page 1456</a> |
| <i>trigger</i>    | Name of a trigger whose mode is to be set    | Must be a local trigger, and all triggers in the list must be defined on the same table or view | <a href="#">Identifier on page 1456</a> |

For example, to change the mode of the unique index **unq\_ssn** on the **cust\_subset** table to filtering, enter the following statement:

```
SET INDEXES unq_ssn FILTERING;
```

You can also use the object-list format to change the mode for a list of constraints, indexes, or triggers that are defined on the same table. Assume that four triggers are defined on the **cust\_subset** table: **insert\_trig**, **update\_trig**, **delete\_trig**, and **execute\_trig**. Also assume that all four triggers are enabled. To disable all triggers except **execute\_trig**, enter this statement:

```
SET TRIGGERS insert_trig, update_trig, delete_trig DISABLED;
```

443. See [Modes for constraints and unique indexes on page 876](#)

444. See [Modes for Triggers and Duplicate Indexes on page 879](#)

If **my\_trig** is a disabled INSTEAD OF trigger on a view, the following statement enables that trigger:

```
SET TRIGGERS my_trig ENABLED;
```

In cluster environments, the SET TRIGGERS statement is not supported on updatable secondary servers. More generally, session-level index, trigger, and constraint modes that the SET Database Object Mode statement specifies are not redirected for UPDATE operations on table objects in databases of secondary servers.

## Table Format

Use the table format to change the mode of all database objects of a specified type that have been defined on the same table or view.

Table Format

**, CONSTRAINTS INDEXES TRIGGERS**

**FOR**

*'owner'* .

*table\_object*

Modes for Constraints and Unique Indexes<sup>445</sup>

Modes for Triggers and Duplicate Indexes<sup>446</sup>

| Element             | Description                                | Restrictions  | Syntax                                  |
|---------------------|--|---|---|
| <i>owner</i>        | Owner of <i>table</i>                      | Must own <i>table</i>   | <a href="#">Owner name on page 1488</a> |
| <i>table_object</i> | Table or view on which objects are defined | Must be a local table or view. Objects defined on a temporary table cannot be set to disabled or filtering modes. | <a href="#">Identifier on page 1456</a> |

This example disables all constraints defined on the **cust\_subset** table:

```
SET CONSTRAINTS FOR cust_subset DISABLED;
```

In table format, you can change the modes of more than one database object type with a single statement. For example, this enables all constraints, indexes, and triggers that are defined on the **cust\_subset** table:

```
SET CONSTRAINTS, INDEXES, TRIGGERS FOR cust_subset ENABLED;
```

In Informix® 10.00 and in earlier versions, you cannot use the SET TRIGGERS option of the SET Database Object Mode statement to disable an inherited trigger selectively within a table hierarchy. In this release, however, disabling a trigger on a table within a hierarchy has no effect on inherited triggers. For example, the following statement disables all triggers on the specified *subtable*, but the statement has no effect on triggers on table objects that are above or below *subtable* within a table hierarchy:

```
SET TRIGGERS FOR subtable DISABLED;
```

445. See [Modes for constraints and unique indexes on page 876](#)

446. See [Modes for Triggers and Duplicate Indexes on page 879](#)

In cluster environments, however, the SET TRIGGERS, SET INDEXES, and SET CONSTRAINTS statements are not supported on updatable secondary servers. Session-level index, trigger, and constraint modes that the SET Database Object Mode statement specifies are not redirected for UPDATE operations on table objects in databases of secondary server

## Modes for constraints and unique indexes

You can specify enabled or disabled mode for a constraint or for a unique index. For tables that the START VIOLATIONS TABLE statement has associated with a violations table and a diagnostics table, you can also use the FILTERING keyword to specify an ERROR mode for processing rows that do not comply with constraints or with unique index requirements.

When you change the mode of a foreign-key constraint to ENABLED or to FILTERING, you can optionally include the NOVALIDATE keyword. This suspends referential-integrity checking for rows that violate the constraint during execution of the SET CONSTRAINTS statement.

This is the syntax for changing the database object mode of constraints or of unique indexes in SET CONSTRAINTS or SET INDEXES statements:

Modes for constraints and unique indexes

**DISABLED**

**ENABLED**

**FILTERING**

**WITHOUT ERROR WITH ERROR**

447

448 **NOVALIDATE**

### Usage

If you specify no mode in the ALTER TABLE or CREATE TABLE statement that creates a constraint, the constraint is enabled by default.

Similarly, if you specify no mode in the CREATE INDEX statement that creates an index, the index is enabled by default.

There is no default mode, however, for database objects in SET Database Object Mode statements. If you specify no mode in the SET CONSTRAINTS or the SET INDEXES options of SET Database Object Mode statements, the statement fails with error -201, and the constraint mode or index mode is unchanged.

The WITHOUT ERROR and WITH ERROR filtering options support DML operations in which the database server tests whether new or modified rows violate constraints or unique indexes on the target table. How the database server processes noncompliant rows in filtering mode also depends on these factors:

- Whether a violations table and a diagnostics table are associated with the table on which the constraint or the unique index is defined.
- Whether input to the associated violations and diagnostics tables is currently enabled or disabled.

447. See [Filtering Modes on page 881](#)

448. Valid for FOREIGN KEY and CHECK constraints only

For more information, see the topics [START VIOLATIONS TABLE statement on page 1011](#) and [STOP VIOLATIONS TABLE statement on page 1024](#).

### Examples of changing constraint modes and unique index modes

The following statement disables the constraint `u100_1`, so that it is still registered in the system catalog, but has no effect:

```
SET CONSTRAINTS u100_1 DISABLED;
```

If `u100_1` is an enabled unique index, rather than a constraint, then the following statement has a similar effect:

```
SET INDEXES u100_1 DISABLED;
```

The following statement enables the referential constraint `u100_1` without validating the foreign-key relationships for each row:

```
SET CONSTRAINTS u100_2 ENABLED NOVALIDATE;
```

#### Warning:

You can specify the new mode of a foreign key constraint as `ENABLED NOVALIDATE`, or as `FILTERING WITH ERROR NOVALIDATE` or `FILTERING WITHOUT ERROR NOVALIDATE`. This can improve performance in load operations, for example, if the data set is known to have a corresponding primary key for every row that is in scope of the foreign key constraint. It is the responsibility of the user, however, to avoid corruption of the database in subsequent DML operations. If you are not sure that the data rows are compliant,

- you should disable the foreign-key constraint,
- load the data into the new database,
- and then enable the foreign-key constrain after its table has been successfully loaded, so that the database server can validate the referential integrity of the data.

The database server automatically drops the `NOVALIDATE` attribute when the `SET CONSTRAINTS` statement completes execution. The following statement enables the same foreign-key constraint and restores automatic validation of the constraint:

```
SET CONSTRAINTS u100_2 ENABLE;
```

When you use the `FILTERING WITHOUT ERROR` keywords to define a filtering mode, subsequent violations of that constraint, or uniqueness violations of that index, do not cause `INSERT`, `DELETE`, `MERGE`, or `UPDATE` operations to fail if some rows violate the constraint or the unique index. In this filtering mode, the DML statement succeeds, but the database server enforces the constraint or the unique index requirement by writing the noncompliant rows to the violations table.

The following statement instructs the database server to write any rows that violate the `r104_11` constraint to the violations table, provided that a violations table is associated with the target table.

```
SET CONSTRAINTS r104_11 FILTERING WITHOUT ERROR;
```

For more information about filtering modes, see the topic [Filtering Modes on page 881](#).

The following statement disables all constraints defined on the `orders` table:

```
SET CONSTRAINTS FOR orders DISABLED;
```

Subsequent DML operations on that table ignore rows that violate constraints on the `orders` table, creating no entries in its violations or diagnostics tables, if those tables exist. If any unique indexes exist on the `orders` table, however, rows that violate uniqueness requirements are processed according to the current modes of the indexes, as listed in the `sysobjstate` system catalog table.

## Enabling foreign-key constraints when an index exists on the referenced table

By default, the database server automatically validates referential constraints when their mode is changed to `ENABLED`. You might be able to save time when the `SET CONSTRAINTS` statement enables a foreign-key constraint, if the referenced table already has a unique index or a primary-key constraint on the column (or on the set of columns) corresponding to the key of the foreign-key constraint.

The database server makes a cost-based decision on how to validate the enabled foreign-key constraint. The index-key algorithm might be faster in many contexts, because it validates the constraint by scanning only the index values, rather than by scanning all the rows in the table.

The database server can consider using the index-key algorithm to validate the foreign-key constraint that it enables, but only if all of the following conditions are satisfied when the `SET CONSTRAINTS ENABLED` statement resets the constraint mode:

- The `SET CONSTRAINTS` statement is enabling only one foreign-key constraint.

If this is the case, the database server needs to check individual values for only the column on which the foreign-key constraint is being enabled. Validating two foreign-key constraints at the same time would require two indices to be used on the same scan, which is not supported.

- The same statement is not enabling a `CHECK` constraint.

If the `SET CONSTRAINTS` statement is enabling more than one constraint, validating `CHECK` constraints requires that every row be checked, rather than individual values. In that case, the index-key algorithm cannot be used for validating the foreign-key constraint.

- The foreign-key columns do not include user-defined data types (UDTs) or built-in opaque data types.

To make the fast index-key algorithm as efficient as possible, it eliminates all the inefficiencies of executing routines associated with user-defined or built-in opaque data types, such as the BOOLEAN and LVARCHAR built-in opaque types.

- The new mode of the foreign-key constraint is not DISABLED.

If it is disabled, then no constraint-checking algorithm is needed, because no checking for referential integrity violations occurs.

- The table is not associated with an active violation table.

Violations tables require that at the time of checking, every row that does not satisfy the new constraint must be inserted into the violation table. Scanning every row for violations prevents the database server from using the faster index-key algorithm that skips duplicate rows.

Except in the case of one or more violating rows, the SET CONSTRAINTS statement can enable and validate a foreign-key constraint when some of these requirements are not satisfied, but the database server will not consider using the index-key algorithm to validate the foreign-key constraint. The additional validation costs for scanning the entire table are generally proportional to the size of the table. These costs can be substantial for very large tables.

When you enable a self-referencing foreign-key constraint, whose REFERENCING clause specifies the same table on which the constraint is defined, the database server can consider an index-key algorithm for validating referential-integrity, if all the conditions listed above are satisfied.

---

[Creating foreign-key constraints when an index exists on the referenced table on page 124](#)

## Modes for Triggers and Duplicate Indexes

You can specify ENABLED or DISABLED as the only object modes for triggers on tables, and for triggers on views, and for indexes that allow duplicate values.

You can specify the modes for triggers or duplicate indexes.

Modes for Triggers and Duplicate Indexes

### **ENABLED DISABLED**

If you specify no mode for an index or for a trigger when you create it or in a subsequent SET Database Object Mode statement, the object is enabled by default.

### **Example of changing the mode of an index**

The following example of the SET INDEXES statement disables the unique **acc\_num\_ix** index, which was created in ENABLED mode by default:

```
CREATE TABLE accounts (
  acc_num INTEGER DEFAULT 1,
  acc_type CHAR(1) DEFAULT 'A',
  acc_descr CHAR(20) DEFAULT 'New Account',
  acc_bal MONEY(9,2)
```

```
acc_id CHAR(32) DEFAULT CURRENT_USER);

CREATE DISTINCT INDEX acc_num_ix ON accounts (accr_num);

SET INDEXES acc_num_ix DISABLED;
```

Here the SET INDEXES statement used the Object-list format to specify the index by name. Because no other index is defined on the **accounts** table, the following SET INDEXES statement that uses the Table format has the same effect:

```
SET INDEXES FOR accounts DISABLED;
```

### Example of changing mode of a trigger

The following example enables a **backup\_accts** trigger that was created in DISABLED mode:

```
SET TRIGGERS backup_accts ENABLED;
```

## Definitions of Database Object Modes

You can use database object modes to control the effects of INSERT, DELETE, and UPDATE statements. Your choice of mode affects the tables whose data you are manipulating, the behavior of the database objects defined on those tables, and the behavior of the data manipulation statements themselves.

### Enabled Mode

Database objects in the enabled mode behave as constraints, indexes, or triggers during DML operations on the table.

If you specify no database object mode when constraints, indexes, or triggers are created, they are enabled by default. The data definition statements CREATE TABLE, ALTER TABLE, CREATE INDEX, and CREATE TRIGGER all create database objects in enabled mode, unless you explicitly specify a different mode.

Which nondefault object modes are available at creation-time depends on the type of object:

- When a trigger or a non-unique index is created, the only keyword alternative to the enabled mode is `DISABLED`.
- When a constraint or a unique index is created, alternatives to the default or explicit `ENABLED` keyword include `DISABLED`, `FILTERING WITH ERROR`, and `FILTERING WITHOUT ERROR`. (But if you only specify `FILTERING`, then `FILTERING WITHOUT ERROR` is the default error mode for `FILTERING` objects.)
- While the ALTER TABLE ADD CONSTRAINT statement is creating a foreign-key or check constraint, however, any of these three modes can instead be specified as additional alternatives to the enabled mode:
  - `ENABLED NOVALIDATE`
  - `FILTERING WITH ERROR NOVALIDATE`
  - `FILTERING WITHOUT ERROR NOVALIDATE`.

When the SET Database Object Mode statement changes the mode of an existing constraint, index, or trigger, however, there no default mode. If you specify no object mode, the SET Database Object Mode statement fails with error -201. If you want to reset the mode of a constraint, index, or trigger to enabled from some other mode, you must explicitly specify the `ENABLED` keyword.

When a database object is successfully enabled, the database server registers that object state in the **sysobjstate** table of the system catalog, and takes that database object into consideration when its table is the target of a subsequent INSERT, DELETE, MERGE, or UPDATE statement (or for Select triggers, a SELECT statement). Thus, an enabled constraint is enforced, an enabled index is updated, and an enabled trigger on a table is executed when the trigger event takes place.

For example, after you set foreign-key constraints and unique indexes to enabled mode, when an INSERT, DELETE, MERGE, or UPDATE operation attempts to violate the referential integrity of the table, the data manipulation operation fails, no rows in the table are changed, and the database server returns an error message.

### ENABLED NOVALIDATE mode for foreign-key or check constraints

While the SET Database Object Mode statement is changing the mode of a foreign-key or check constraint to ENABLED, the database server validates the constraint by examining every row in the constrained table to verify the constraint conditions. This validation can require significant time and resources. You can instead bypass the search for violating rows during the SET Database Object mode operation by including the **NOVALIDATE** keyword to change the constraint mode to ENABLED NOVALIDATE. For large tables, specifying **ENABLED NOVALIDATE** can substantially reduce the time required to enable the constraint.

After the SET CONSTRAINTS option to the SET Database Object Mode statement successfully enables a foreign-key or check constraint, the constraint mode is registered as enabled (E) in the **sysobjstate** system catalog table. The **NOVALIDATE** keyword, that had prevented checking for referential-integrity or check condition violations while the SET CONSTRAINTS statement was running, is not encoded anywhere in the system catalog, and has no further effect on the object mode or the behavior of the constraint.

Until it is dropped or disabled, that constraint is enforced during subsequent DML operations on its table, in order to maintain the referential integrity of the database.

## Disabled Mode

When a database object is disabled, the database server ignores it during the execution of an INSERT, DELETE, MERGE, SELECT, or UPDATE statement. A disabled constraint is not enforced, a disabled index is not updated, and a disabled trigger is not executed when the trigger event takes place.

When you disable constraints and unique indexes, any data manipulation statement that violates the restriction of the constraint or unique index succeeds (that is, the target row is changed), and the database server does not return an error message.

You can use the disabled mode to add a new constraint or new unique index to an existing table, even if some rows in the table do not satisfy the new integrity specification. Disabling can also be efficient in LOAD operations.

For information on adding a constraint, see [Adding a Constraint That Existing Rows Violate on page 153](#) in the ALTER TABLE statement. For information on adding a unique index, see [Adding a Unique Index When Duplicate Values Exist in the Column on page 278](#) in the CREATE INDEX statement.

## Filtering Modes

A constraint or unique index in a filtering mode can insert into an associated violations table any rows that fail to comply with the constraint or index during DML operation. This mode also supports WITH ERROR and WITHOUT ERROR options for processing referential-integrity violations from INSERT, DELETE, MERGE, and UPDATE statements.

When a constraint or unique index is in FILTERING WITH ERROR mode, the database server returns a referential-integrity violation error message after the INSERT, DELETE, MERGE, or UPDATE statement results in one or more rows that are not in compliance with the unique index or with the constraint.

By default, the `FILTERING` keyword with no error option specifies the FILTERING WITHOUT ERROR object mode.

### Effects of FILTERING mode in DML operations

When a constraint or unique index is in FILTERING WITHOUT ERROR mode, the INSERT, DELETE, MERGE, or UPDATE statement succeeds, but the database server enforces the constraint or the unique-index requirement by writing any failed rows to the violations table associated with the target table. Diagnostic information about the constraint violation or unique-index violation is written to the diagnostics table associated with the target table.

In data manipulation operations, filtering mode has the following specific effects on INSERT, UPDATE, and DELETE statements:

- A constraint violation during an INSERT statement causes the database server to make a copy of the nonconforming record and write it to the violations table. The database server does not write the nonconforming record to the target table.  
If the INSERT statement is not a singleton INSERT, the rest of the insert operation proceeds with the next record.
- A constraint violation or unique-index violation during an UPDATE statement causes the database server to make a copy of the existing record that was to be updated and write it to the violations table. The database server also makes a copy of the new record and writes it to the violations table, but the actual record is not updated in the target table. If the UPDATE statement is not a singleton update, the rest of the update operation proceeds with the next record.
- A constraint violation or unique-index violation during a DELETE statement causes the database server to make a copy of the record that was to be deleted and write it to the violations table. The database server does not delete the actual record in the target table. If the DELETE statement is not a singleton delete, the rest of the delete operation proceeds with the next record.
- In MERGE statements, the component INSERT, DELETE, or UPDATE operations are processed as respectively described above.

In all of these cases, the database server sends diagnostic information about each constraint violation or unique-index violation to the diagnostics table associated with the target table.

For information on the structure of the records that the database server writes to the violations and diagnostics tables, see [Structure of the violations table on page 1014](#) and [Structure of the diagnostics table on page 1020](#).

## FILTERING NOVALIDATE modes

While the SET Database Object Mode statement is changing the mode of a foreign-key or check constraint to FILTERING WITHOUT ERROR or to FILTERING WITH ERROR, the database server validates the constraint by examining every row in the constrained table. For large tables, this validation can require significant time and resources.

You can instead bypass the search for violating rows during the SET Database Object mode operation by including the `NOVALIDATE` keyword to change the constraint mode to FILTERING WITHOUT ERROR NOVALIDATE or to FILTERING WITH ERROR NOVALIDATE, as in these examples for foreign-key constraints:

```
SET CONSTRAINTS (refcon_1, refcon_2) FILTERING WITH ERROR;
SET CONSTRAINTS (refcon_3, refcon_4) FILTERING WITHOUT ERROR;
```

For constraints on large tables that need to be relocated, specifying `NOVALIDATE` for ENABLED or FILTERING modes can substantially reduce the time required to change the mode of the constraint to a filtering mode.

After the SET Database Object Mode statement successfully enables a constraint in a NOVALIDATE filtering mode, the constraint is registered in FILTERING WITHOUT ERROR mode (**F**) or in FILTERING WITH ERROR mode (**G**) in the `sysobjstate` system catalog table. Because the `NOVALIDATE` keyword has no encoding in the system catalog, it has no subsequent effect on the behavior of the database server. The database server enforces the foreign-key constraint during subsequent DML operations as the SET CONSTRAINTS statement specified, with or without integrity violation errors, to maintain the referential integrity of the database.

### Important:

When the ALTER TABLE ADD CONSTRAINT statement defines an ENABLED referential constraint in NOVALIDATE mode on a table that contains data, the database server can achieve the same efficiencies of bypassing constraint validation that are described above for the SET CONSTRAINTS statement. For more information about the `NOVALIDATE` option in ALTER TABLE operations that define new referential constraints, see [Creating foreign-key constraints in NOVALIDATE modes on page 128](#).

## Starting and Stopping the Violations and Diagnostics Tables

### About this task

You must use the START VIOLATIONS TABLE statement to start the violations and diagnostics tables for the target table on which the database objects are defined, either before you set any database objects that are defined on the table to the filtering mode, or after you set database objects to filtering, but before any users issue INSERT, DELETE, or UPDATE statements.

If you want to stop the database server from filtering bad records to the violations table and sending diagnostic information about each bad record to the diagnostics table, you must issue a STOP VIOLATIONS TABLE statement.

For further information on these statements, see [START VIOLATIONS TABLE statement on page 1011](#) and [STOP VIOLATIONS TABLE statement on page 1024](#).

## Error Options for Filtering Mode

When you set the mode of a constraint or unique index to filtering, you can specify one of two error options. These error options control whether the database server displays an integrity-violation error message when it encounters bad records during execution of data manipulation statements:

- The `WITH ERROR` option instructs the database server to return a referential integrity-violation error message after executing an `INSERT`, `DELETE`, or `UPDATE` statement in which one or more of the target rows causes a constraint violation or a unique-index violation.
- The `WITHOUT ERROR` option is the default. This option prevents the database server from issuing a referential integrity-violation error message to the user after an `INSERT`, `DELETE`, or `UPDATE` statement causes a constraint violation or a unique-index violation.

## Effect of Filtering Mode on the Database

The net effect of the filtering mode is that the contents of the target table always satisfy all constraints on the table and any unique-index requirements on the table.

In addition, the database server does not lose any data values that violate a constraint or unique-index requirement, because non-conforming records are sent to the violations table, and diagnostic information about those records is sent to the diagnostics table.

Furthermore, when filtering mode is in effect, insert, delete, and update operations on the target table do not fail when the database server encounters bad records. These operations succeed in adding all the good records to the target table. Thus, filtering mode is appropriate for large-scale batch updates of tables. The user can fix records that violate constraints and unique-index requirements after the fact. The user does not need to fix the bad records before the batch update to avoid losing the bad records during the batch update.

## SET DATASKIP statement

Use the `SET DATASKIP` statement to control whether the database server skips a dbspace that is unavailable during the processing of a transaction.

This statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

**SET DATASKIP**

**ON**

*, dbspace*

**OFF DEFAULT**

| Element        | Description                 | Restrictions                    | Syntax                                  |
|----------------|-----------------------------|---------------------------------|---|
| <i>dbspace</i> | Name of the skipped dbspace | Must exist at time of execution | <a href="#">Identifier on page 1456</a> |

## Usage

SET DATASKIP allows you to reset at runtime the Dataskip feature, which controls whether the database server skips a dbspace that is unavailable (for example, due to a media failure) in the course of processing a transaction.

In Informix® ESQL/C, the warning flag `sqlca.sqlwarn.sqlwarn6` is set to `w` if a dbspace is skipped. See also the *Informix® ESQL/C Programmer's Manual*.

In Informix®, this statement applies only to tables that are fragmented across dbspaces or partitions. It does not apply to blobspaces nor to sbspaces.

Specifying SET DATASKIP ON without including a *dbspace* instructs the database server to skip any dbspaces in the fragmentation list that are unavailable. You can use the `onstat -d` or `-D` options to determine whether a dbspace is down.

When you specify SET DATASKIP ON *dbspace*, you are instructing the database server to skip the specified *dbspace* if it is unavailable.

If you specify SET DATASKIP OFF, the Dataskip feature is disabled. If you specify SET DATASKIP DEFAULT, the database server uses the setting that is specified in the DATASKIP configuration parameter in ONCONFIG file.

## Examples

The following skips `dbsp1` for the current session:

```
SET DATASKIP ON dbsp1;
```

The following sets the value of **DATASKIP** to the value specified in `onconfig`:

```
SET DATASKIP DEFAULT;
```

The following switches **DATASKIP** off so that all dbspaces are used.

```
SET DATASKIP OFF;
```

## Circumstances When a Dbspace Cannot Be Skipped

The database server cannot skip a dbspace under certain conditions. The following list outlines those conditions:

- Referential constraint checking

When you want to delete a parent row, the child rows must also be available for deletion, and must exist in an available fragment.

When you want to insert a new child row, the parent row must be found in the available fragments.

- Updates

When you perform an update that moves a record from one fragment to another, both fragments must be available.

- Inserts

When you try to insert records in a expression-based fragmentation strategy and the dbspace is unavailable, an error is returned.

When you try to insert records in a round-robin fragment-based strategy, and a dbspace is down, the database server inserts the rows into any available dbspace.

When no dbspace is available, an error is returned.

- Indexing

When you perform updates that affect the index, such as when you insert or delete rows, or update an indexed column, the index must be available.

When you try to create an index, the dbspace you want to use must be available.

- Serial keys

The first fragment is used to store the current serial-key value internally. This is not visible to you except when the first fragment becomes unavailable and a new serial key value is required, which can happen during INSERT statements.

## SET DEBUG FILE statement

Use the SET DEBUG FILE statement to identify the file that is to receive the runtime trace output of an SPL routine.

This statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

#### SET DEBUG FILE TO

*'filename' filename\_var expression*

#### WITH APPEND

| Element             | Description  | Restrictions   | Syntax                                      |
|---------------------|--|--|---|
| <i>expression</i>   | Expression that returns a filename                                   | Must be a valid filename                                     | <a href="#">Expression on page 1193</a>     |
| <i>filename</i>     | Pathname of the file that contains the output of the TRACE statement | See <a href="#">Using the WITH APPEND Option on page 886</a> | <a href="#">Quoted String on page 1424.</a> |
| <i>filename_var</i> | Host variable storing <i>filename</i> string                         | Must be a character type                                     | Language specific                           |

### Usage

This statement specifies the file to which the database server writes the output from the TRACE statement in the SPL routine. Each time the TRACE statement is executed, the trace information is added to this output file.

---

#### Related reference

[TRACE on page 1134](#)

## Using the WITH APPEND Option

The output file that you specify in the SET DEBUG FILE statement can be a new file or existing file. If you specify an existing file, its current contents are deleted when you issue the SET DEBUG FILE TO statement. The first execution of a TRACE statement sends trace output to the beginning of the file.

If you include the WITH APPEND option, the current contents of the file are preserved when you issue the SET DEBUG FILE statement. The first execution of a TRACE statement adds the new trace output to the end of the file.

If you specify a new file in the SET DEBUG FILE TO statement, it makes no difference whether you include the WITH APPEND option. The first execution of a TRACE statement sends trace output to the beginning of the new file whether you include or omit the WITH APPEND option.

## Closing the Output File

### About this task

To close the file that the SET DEBUG FILE TO statement opened, issue another SET DEBUG FILE TO statement with another filename. You can then read or edit the contents of the first file.

## Redirecting Trace Output

You can use the SET DEBUG FILE TO statement outside an SPL routine to direct the trace output of the SPL routine to a file. You can also use this statement within an SPL routine to redirect its own output.

## Location of the Output File

If you execute the SET DEBUG FILE statement with a simple filename on a local database, the output file is located in your current directory. If your current database is on a remote database server, the output file is located in your home directory on the remote database server. If you provide a full pathname for the debug file, the file is placed in the directory that you specify on the remote database server. If you do not have write permissions in the directory, you receive an error.

The following example sends the output of the SET DEBUG FILE TO statement to a file called **debug.out**:

```
SET DEBUG FILE TO 'debug' || '.out';
```

## SET DEFERRED\_PREPARE statement

Use the SET DEFERRED\_PREPARE statement to control whether a client process postpones sending a PREPARE statement to the database server until the OPEN or EXECUTE statement is sent.

Only Informix® supports this statement, which is an extension to the ANSI/ISO standard for SQL. You can use this statement only with Informix® ESQL/C.

### Syntax

**SET DEFERRED\_PREPARE**

**ENABLED**

**DISABLED**

## Usage

By default, the SET DEFERRED\_PREPARE statement causes the application program to delay sending the PREPARE statement to the database server until the OPEN or EXECUTE statement is executed. In effect, the PREPARE statement is bundled with the other statement so that one round-trip of messages, instead of two, is sent between the client and the server. This Deferred-Prepare feature can affect the following series of Dynamic SQL statement:

- PREPARE, DECLARE, OPEN statement blocks that operate with the FETCH or PUT statements
- PREPARE followed by the EXECUTE or EXECUTE IMMEDIATE statement

You can specify ENABLED or DISABLED options for SET DEFERRED\_PREPARE.

If you specify no option, the default is ENABLED. The following example enables the Deferred-Prepare feature by default:

```
EXEC SQL set deferred_prepare;
```

The ENABLED option enables the Deferred-Prepare feature within the application. The following example explicitly specifies the ENABLED option:

```
EXEC SQL set deferred_prepare enabled;
```

After an application issues SET DEFERRED\_PREPARE ENABLED, the Deferred-Prepare feature is enabled for subsequent PREPARE statements in the application. The application then exhibits the following behavior:

- The sequence PREPARE, DECLARE, OPEN sends the PREPARE statement to the database server with the OPEN statement. If the prepared statement has syntax errors, the database server does not return error messages to the application until the application declares a cursor for the prepared statement and opens the cursor.
- The sequence PREPARE, EXECUTE sends the PREPARE statement to the database server with the EXECUTE statement. If a prepared statement contains syntax errors, the database server does not return error messages to the application until the application attempts to execute the prepared statement.

If Deferred-Prepare is enabled in a PREPARE, DECLARE, OPEN statement block that contains a DESCRIBE statement, the DESCRIBE statement must follow the OPEN statement rather than the PREPARE statement. If the DESCRIBE follows PREPARE, the DESCRIBE statement results in an error.

Use the DISABLED option to disable the Deferred-Prepare feature within the application. The following example specifies the DISABLED option:

```
EXEC SQL set deferred_prepare disabled;
```

If you specify the DISABLED option, the application sends each PREPARE statement to the database server when the PREPARE statement is executed.

[DESCRIBE statement on page 495](#)

[EXECUTE statement on page 541](#)

[OPEN statement on page 677](#)

[PREPARE statement on page 687](#)

[FETCH statement on page 561](#)

## Example of SET DEFERRED\_PREPARE

The following code fragment shows a SET DEFERRED\_PREPARE statement with a PREPARE, EXECUTE statement block. In this case, the database server executes the PREPARE and EXECUTE statements all at once:

```
EXEC SQL BEGIN DECLARE SECTION;
    int a;
EXEC SQL END DECLARE SECTION;
EXEC SQL allocate descriptor 'desc';
EXEC SQL create database test;
EXEC SQL create table x (a int);

/* Enable Deferred-Prepare feature */
EXEC SQL set deferred_prepare enabled;
/* Prepare an INSERT statement */
EXEC SQL prepare ins_stmt from 'insert into x values(?)';
a = 2;
EXEC SQL EXECUTE ins_stmt using :a;
if (SQLCODE)
    printf("EXECUTE : SQLCODE is %d\n", SQLCODE);
```

## Using Deferred-Prepare with OPTOFC

You can use the Deferred-Prepare and Open-Fetch-Close Optimization (OPTOFC) features in combination. The OPTOFC feature delays sending the OPEN message to the database server until the FETCH message is sent. The following situations occur if you enable the Deferred-Prepare and OPTOFC features at the same time:

- If the text of a prepared statement contains syntax errors, the error messages are not returned to the application until the first FETCH statement is executed.
- A DESCRIBE statement cannot be executed until after the FETCH statement.
- You must issue an ALLOCATE DESCRIPTOR statement before a DESCRIBE or GET DESCRIPTOR statement can be executed.

The database server performs an internal execution of a SET DESCRIPTOR statement which sets the TYPE, LENGTH, DATA, and other fields in the system descriptor area. You can specify a GET DESCRIPTOR statement after the FETCH statement to see the data that is returned.

## SET DESCRIPTOR statement

Use the SET DESCRIPTOR statement to set values in a system-descriptor area (SDA).

Use this statement with Informix® ESQL/C.

**Syntax****SET DESCRIPTOR**

```
descriptor_var 'descriptor '
```

**COUNT=**

```
total_items_var total_items
```

**VALUE**

```
item_num_var item_num
```

```
, Item Descriptor449
```

| Element                | Description   | Restrictions  | Syntax                                      |
|------------------------|---|---|---|
| <i>descriptor</i>      | String that identifies the SDA to which values are assigned                       | System-descriptor area (SDA) must be previously allocated                         | <a href="#">Quoted String on page 1424</a>  |
| <i>descriptor_var</i>  | Host variable that stores <i>descriptor</i>                                       | Same restrictions as <i>descriptor</i>  | Language specific                           |
| <i>item_num</i>        | Unsigned integer that specifies ordinal position of an item descriptor in the SDA | 0 < <i>item_num</i> (number of item descriptors specified when SDA was allocated) | <a href="#">Literal Number on page 1419</a> |
| <i>item_num_var</i>    | Host variable that stores <i>item_num</i>   | Same restrictions as <i>item_num</i>  | Language specific                           |
| <i>total_items</i>     | Unsigned integer that specifies how many items the SDA describes                  | Same restrictions as <i>item_num</i>  | <a href="#">Literal Number on page 1419</a> |
| <i>total_items_var</i> | Host variable that stores <i>total_items</i>                                      | Same restrictions as <i>total_items</i>   | Language specific                           |

**Usage**

The SET DESCRIPTOR statement can be used after you have described SELECT, EXECUTE FUNCTION, EXECUTE PROCEDURE, ALLOCATE DESCRIPTOR, or INSERT statements with the DESCRIBE ... USING SQL DESCRIPTOR statement.

SET DESCRIPTOR can assign values to a system-descriptor area in these cases:

- To set the **COUNT** field of a system-descriptor area to match the number of items for which you are providing descriptions in the system-descriptor area
- To set the item descriptor for each value for which you are providing descriptions in the system-descriptor area
- To modify the contents of an item-descriptor field

If an error occurs during the assignment to any identified system-descriptor fields, the contents of all identified fields are set to 0 or NULL, depending on the data type of the variable.

## Using the COUNT Clause

Use the COUNT clause to set the number of items that are to be used in the system-descriptor area. If you allocate a system-descriptor area with more items than you are using, you need to set the **COUNT** field to the number of items that you are actually using. The following example shows a fragment of the Informix® ESQL/C program:

```
EXEC SQL BEGIN DECLARE SECTION;
    int count;

EXEC SQL END DECLARE SECTION;

EXEC SQL allocate descriptor 'desc_100'; /*allocates for 100 items*/
    count = 2;
EXEC SQL set descriptor 'desc_100' count = :count;
```

## Using the VALUE Clause

Use the VALUE clause to assign values from host variables into fields of a system-descriptor area. You can assign values for items for which you are providing a description (such as parameters in a WHERE clause), or you can modify values for items after you use a DESCRIBE statement to fill the fields for an UPDATE or INSERT statement.

## Item Descriptor

Use the Item Descriptor portion of the SET DESCRIPTOR statement to set value for an individual field in a system-descriptor area.

Item Descriptor

452. See [Literal INTERVAL on page 1418](#)

453. See [Quoted String on page 1424](#)

## Setting the TYPE or ITYPE Field

Use these integer values to set the value of **TYPE** or **ITYPE** for each item.

| SQL Data Type | Integer Value | X-Open<br>Integer Value | SQL Data Type | Integer Value | X-Open<br>Integer Value |
|---------------|---------------|-------------------------|---------------|---------------|-------------------------|
| CHAR          | 0             | 1                       | MONEY         | 8             | -                       |
| SMALLINT      | 1             | 4                       | DATETIME      | 10            | -                       |
| INTEGER       | 2             | 5                       | BYTE          | 11            | -                       |
| FLOAT         | 3             | 6                       | TEXT          | 12            | -                       |
| SMALLFLOAT    | 4             | -                       | VARCHAR       | 13            | -                       |
| DECIMAL       | 5             | 3                       | INTERVAL      | 14            | -                       |
| SERIAL        | 6             | -                       | NCHAR         | 15            | -                       |
| DATE          | 7             | -                       | NVARCHAR      | 16            | -                       |

The following table lists integer values that represent additional data types available with Informix®.

| SQL Data Type               | Integer Value | SQL Data Type               | Integer Value |
|-----------------------------|---------------|-----------------------------|---------------|
| INT8                        | 17            | Fixed-length OPAQUE type    | 41            |
| SERIAL8                     | 18            | LVARCHAR (client-side only) | 43            |
| SET                         | 19            | BOOLEAN                     | 45            |
| MULTISET                    | 20            | BIGINT                      | 52            |
| LIST                        | 21            | BIGSERIAL                   | 53            |
| ROW (unnamed)               | 22            | IDSSECURITYLABEL            | 2061          |
| COLLECTION                  | 23            | ROW (named)                 | 4118          |
| Variable-length OPAQUE type | 40            |                             |               |

The same **TYPE** constants can also appear in the **syscolumns.coltype** column in the system catalog; see *Informix® Guide to SQL: Reference*.

For code that is easier to maintain, use the predefined constants for these SQL data types instead of their actual integer values. These constants are defined in the **\$INFORMIX/incl/public/sqltypes.h** header file. You cannot, however, use the actual constant name in the SET DESCRIPTOR statement. Instead, assign the constant to an integer host variable and specify the host variable in the SET DESCRIPTOR statement file.

The following example shows how you can set the **TYPE** field in Informix® ESQL/C:

```
main()
{
```

```
EXEC SQL BEGIN DECLARE SECTION;
    int itemno, type;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL allocate descriptor 'desc1' with max 5;
...
type = SQLINT; itemno = 3;
EXEC SQL set descriptor 'desc1' value :itemno type = :type;
}
```

This information is identical for **ITYPE**. Use **ITYPE** when you create a dynamic program that does not comply with the X/Open standard.

## Compiling Without the -xopen Option

If you compile without the **-xopen** option, the normal Informix® SQL code is assigned for **TYPE**. You must be careful not to mix normal and X/Open modes, because errors can result. For example, if a data type is not defined under X/Open mode, but is defined under normal mode, executing a SET DESCRIPTOR statement can result in an error.

## Setting the TYPE Field in X/Open Programs

In X/Open mode, you must use the X/Open set of integer codes for the data type in the **TYPE** field.

If you use the **ILENGTH**, **IDATA**, or **ITYPE** fields in a SET DESCRIPTOR statement, a warning message appears. The warning indicates that these fields are not standard X/Open fields for a system-descriptor area.

For code that is easier to maintain, use the predefined constants for these X/Open SQL data types instead of their actual integer value. These constants are defined in the **\$INFORMIX/incl/public/sqlxtype.h** header file.

## Using DECIMAL or MONEY Data Types

If you set the **TYPE** field for a DECIMAL or MONEY data type, and you want to use a scale or precision other than the default values, set the **SCALE** and **PRECISION** fields. You do not need to set the **LENGTH** field for a DECIMAL or MONEY item; the **LENGTH** field is set accordingly from the **SCALE** and **PRECISION** fields.

## Using DATETIME or INTERVAL Data Types

If you set the **TYPE** field for a DATETIME or INTERVAL value, the **DATA** field can be a DATETIME or INTERVAL literal or a character string. If you use a character string, the **LENGTH** field must be the encoded qualifier value.

To determine the encoded qualifiers for a DATETIME or INTERVAL character string, use the **datetime** and **interval** macros in the **datetime.h** header file.

If you set **DATA** to a host variable of DATETIME or INTERVAL, you do not need to set **LENGTH** explicitly to the encoded qualifier integer.

## Setting the DATA or IDATA Field

When you set the **DATA** or **IDATA** field, use the appropriate type of data (character string for CHAR or VARCHAR, integer for INTEGER, and so on).

If any value other than **DATA** is set, the value of **DATA** is undefined. You cannot set the **DATA** or **IDATA** field for an item without setting **TYPE** for that item. If you set the **TYPE** field for an item to a character type, you must also set the **LENGTH** field. If you do not set the **LENGTH** field for a character item, you receive an error.

## Setting the LENGTH or ILENGTH Field

If your **DATA** or **IDATA** field contains a character string, you must specify a value for **LENGTH**. If you specify `LENGTH=0`, **LENGTH** is automatically set to the maximum length of the string. The **DATA** or **IDATA** field can contain a literal character string of up to 368-bytes, or a character string derived from a character variable of a CHAR or VARCHAR data type. This provides a method to determine dynamically the length of a string in the **DATA** or **IDATA** field.

If a DESCRIBE statement precedes a SET DESCRIPTOR statement, **LENGTH** is automatically set to the maximum length of the character field that is specified in your table.

This information is identical for **ILENGTH**. Use **ILENGTH** when you create a dynamic program that does not comply with the X/Open standard.

## Setting the INDICATOR Field

If you want to put a NULL value into the system-descriptor area, set the **INDICATOR** field to `-1` and do not set the **DATA** field.

If you set the **INDICATOR** field to `0` to indicate that the data is not NULL, you must set the **DATA** field.

## Setting Opaque-Type Fields

The following item-descriptor fields provide information about a column that has an opaque type as its data type:

- The **EXTYPEID** field stores the extended identifier for the opaque type. This integer value must correspond to a value in the **extended\_id** column of the **sysxdtypes** system catalog table.
- The **EXTYPENAME** field stores the name of the opaque type. This character value must correspond to a value in the **name** column of the row with the matching **extended\_id** value in the **sysxdtypes** system catalog table.
- The **EXTYPELENGTH** field stores the length of the opaque-type name. This integer value is the length, in bytes, of the string in the **EXTYPENAME** field.
- The **EXTYPEOWNERNAME** field stores the name of the opaque-type owner. This character value must correspond to a value in the **owner** column of the row with the matching **extended\_id** value in the **sysxdtypes** system catalog table.
- The **EXTYPEOWNERLENGTH** field stores the length of the value in the **EXTYPEOWNERNAME** field. This integer value is the length, in bytes, of the string in the **EXTYPEOWNERNAME** field.

For more information on the **sysxdtypes** system catalog table, see the *Informix® Guide to SQL: Reference*.

## Setting Distinct-Type Fields

The following item-descriptor fields provide information about a column that has a distinct type as its data type:

- The **SOURCEID** field stores the extended identifier for the source data type.

Set this field if the source type of the distinct type is an opaque data type. This integer value must correspond to a value in the **source** column for the row of the **sysxdtypes** system catalog table whose **extended\_id** value matches that of the distinct type you are setting.

- The **SOURCTYPE** field stores the data type constant for the source data type.

This value is the data type constant for the built-in data type that is the source type for the distinct type. The codes for the **SOURCTYPE** field are the same as those for the **TYPE** field (page [Setting the TYPE or ITYPE Field on page 892](#)). This integer value must correspond to the value in the **type** column for the row of the **sysxdtypes** system catalog table whose **extended\_id** value matches that of the distinct type you are setting.

For more information on the **sysxdtypes** system catalog table, see the *Informix® Guide to SQL: Reference*.

## Modifying Values Set by the DESCRIBE Statement

You can use a DESCRIBE statement to modify the contents of a system-descriptor area after it is set.

After you use DESCRIBE on a SELECT or an INSERT statement, you must check to determine whether the **TYPE** field is set to either **11** or **12** to indicate a TEXT or BYTE data type. If **TYPE** contains an **11** or a **12**, you must use the SET DESCRIPTOR statement to reset **TYPE** to **116**, which indicates FILE type.

## SET ENCRYPTION PASSWORD statement

Use the SET ENCRYPTION PASSWORD statement to define or reset a *session password* for the encryption and decryption of character, BLOB, or CLOB values.

Only Informix® supports this statement, which is an extension to the ANSI/ISO standard for SQL. You can use this statement with ESQL/C.

### Syntax

**SET ENCRYPTION PASSWORD**'*password*'

**WITH HINT**'*hint*'

| Element         | Description   | Restrictions   | Syntax                                  |
|-----------------|---|--|---|
| <i>hint</i>     | String that <b>GETHINT</b> returns from an encrypted argument | (0 byte) <i>hint</i> (32 bytes). Do not include the <i>password</i> in the <i>hint</i> . | <a href="#">Expression on page 1193</a> |
| <i>password</i> | Password (or a multi-word phrase) for data encryption         | (6 bytes) <i>password</i> (120 bytes). Do not specify your login password.               | <a href="#">Expression on page 1193</a> |

## Usage

The SET ENCRYPTION PASSWORD statement declares a password to support data confidentiality through built-in functions that use the Triple-DES or AES algorithms for encryption and decryption. These functions enable the database to store sensitive data in an encrypted format that prevents anyone who cannot provide the secret password from viewing, copying, or modifying encrypted data.

The password is not stored as plain text in the database and is not accessible to the DBA. This security feature is independent of the Trusted Facility feature.

**Important:** By default, communication between client systems and Informix® is in plain text. Unless the database is accessible only by a secure network, the DBA must enable the encryption communication support module (ENCCSM) to provide data encryption between the database server and any client system. Otherwise, an attacker might read the password and use it to access encrypted data.

If the network is not secure, all of the database servers in a distributed query need ENCCSM enabled, so that the password is not transmitted as plain text. For information about how to enable a communication support module (CSM), see your *Informix® Administrator's Guide*.

**Note:** Support for Communication Support Module (CSM) is removed starting Informix Server 14.10.xC9 . You should use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) instead.

Operations on encrypted data tend to be slower than corresponding operations on plain text data, but use of this feature has no effect on unencrypted data.

The SET ENCRYPTION PASSWORD statements can be prepared, and EXECUTE IMMEDIATE can process a prepared SET ENCRYPTION PASSWORD statement.

## Storage Requirements for Encryption

Use the **ENCRYPT\_AES** or **ENCRYPT\_TDES** built-in functions to encrypt data. Encrypted values of character data types are stored in BASE64 format (also called Radix-64). For character data, this requires significantly more storage than the corresponding unencrypted data. Omitting the *hint* can reduce encryption overhead by more than 50 bytes for each encrypted value. It is the responsibility of the user to make sufficient storage space available for encrypted values.

The following table lists the data types that can be encrypted, and built-in functions that you can use to encrypt and decrypt values of those data types:

| Original Data Type | Encrypted Data Type | BASE64 Format | Decryption Function   |
|--------------------|---------------------|---------------|-----------------------|
| CHAR               | CHAR                | Yes           | <b>DECRYPT_CHAR</b>   |
| NCHAR              | NCHAR               | Yes           | <b>DECRYPT_CHAR</b>   |
| VARCHAR            | VARCHAR             | Yes           | <b>DECRYPT_CHAR</b>   |
| NVARCHAR           | NVARCHAR            | Yes           | <b>DECRYPT_CHAR</b>   |
| LVARCHAR           | LVARCHAR            | Yes           | <b>DECRYPT_CHAR</b>   |
| BLOB               | BLOB                | No            | <b>DECRYPT_BINARY</b> |
| CLOB               | BLOB                | No            | <b>DECRYPT_CHAR</b>   |

You cannot encrypt a column of the `IDSSECURITYLABEL` data type.

If the encrypted `VARCHAR` (or `NVARCHAR`) value is longer than the 255 byte maximum size for those data types, the encryption function returns a `CHAR` (or `NCHAR`) value of sufficient size to store the encrypted value.

**DECRYPT\_BINARY** and **DECRYPT\_CHAR** both return the same value from encrypted `CHAR`, `NCHAR`, `VARCHAR`, `NVARCHAR`, or `LVARCHAR` values. No built-in encryption or decryption functions support `BYTE` or `TEXT` data types, but you can use `BLOB` data types to encrypt very large strings.

**Warning:** If the declared size of a database column in which you intend to store encrypted data is smaller than the encrypted data length, truncation occurs when you insert the encrypted data into the column. The truncated data cannot subsequently be decrypted, because the data length indicated in the header of the encrypted string does not match what the column stores. To avoid truncation, make sure that any column storing encrypted strings has sufficient length. (See the cross-reference in the next paragraph for details of how to calculate encrypted string lengths.)

Besides the unencrypted data length, the storage required for encrypted data depends on the encoding format, on whether you specify a *hint*, and on the block size of the encryption function. For a formula to estimate the encrypted size, see "Calculating storage requirements for encrypted data" on page [Calculating storage requirements for encrypted data on page 1285](#).

## Specifying a Session Password and Hint

The required *password* specification can be quoted strings or other character expression that evaluates to a string whose length is at least 6 bytes but no more than 128 bytes. The optional *hint* can specify a string no longer than 32 bytes.

The password or *hint* can be a single word or several words. The *hint* should be a word or phrase that helps you to remember the *password*, but does not include the *password*. You can subsequently execute the built-in **GETHINT** function (with an encrypted value as its argument) to return the plain text of *hint*.

The following ESQL/C program fragment defines a routine that includes the `SET ENCRYPTION PASSWORD` statement and executes DML statements:

```

process_ssn( )
{
EXEC SQL BEGIN DECLARE SECTION;
char password[128];
char myhint[33];
char myid[16], myssn[16];
EXEC SQL END DECLARE SECTION;
. . .
EXEC SQL SET ENCRYPTION PASSWORD :password WITH HINT :myhint;
...
EXEC SQL INSERT INTO tab1 VALUES (:abcd', ENCRYPT_AES("111-22-3333"));
EXEC SQL SELECT Pid, DECRYPT(ssn, :password) INTO :myid, :myssn;
...
EXEC SQL SELECT GETHINT(ssn) INTO :myhint, WHERE id = :myid;
}

```

## Levels of Encryption

You can use SET ENCRYPTION PASSWORD with encryption and decryption functions to support these granularities of encryption in the database.

- **Column-Level Encryption:** All values in a given column of a database table are encrypted using the same password, the same encryption algorithm, and the same encryption mode. (In this case, you can save disk space by storing the *hint* outside the encrypted column, rather than repeating it in every row.)
- **Cell-Level Encryption:** Values of a given column in different rows of the same database table are encrypted using different passwords, or different encryption algorithms, or different encryption modes. This technique is sometimes necessary to protect personal data. (*Row-column level encryption* and *set-column level encryption* are both synonyms for cell-level encryption.)

Cell-level encryption can cause substantial maintenance costs. If you implement this level of encryption, your application is responsible for determining which rows contain encrypted data and for using the correct code to handle the data. The built-in decryption functions of Informix® fail with error -26005 if they are applied to unencrypted data. The simplest way to avoid this error is to use column-level encryption rather than cell-level encryption.

If you do not use encryption functions, people might enter unencrypted data into columns that are meant to contain encrypted data. To ensure that data entered into a field is always encrypted, use views and INSTEAD OF triggers.

## Protecting Passwords

Passwords and hints that you declare with SET ENCRYPTION PASSWORD are not stored as plain text in any table of the system catalog, which also maintains no record of which columns or tables contain encrypted data.

To prevent other users from accessing the plain text of encrypted data or of a password, however, you must avoid actions that might compromise the secrecy of a password:

- Do not create a functional index using a decryption function. (This would store plain-text data in the database, defeating the purpose of encryption.)
- On a network that is not secure, always work with encrypted data, or use session encryption, because the SQL communication between client and server sends passwords, hints, and the data to be encrypted as plain text.
- Do not store passwords in a trigger or in a UDR that exposes the password to the public.
- Do not set the session password prior to creating any view, trigger, procedure, or UDR. Set the session password only when you use the object. Otherwise, the password might be visible in the schema to other users, and queries executed by other users might return unencrypted data. The following example shows a procedure that includes an encrypted password:

```
-- reset session encryption password
set encryption password null;

-- create procedure without password
create procedure p1 ();
  insert into tab2 select (decrypt_char (col1))
  from tab1;
end procedure;

-- set session encryption password
set encryption password ("PASSWD2");

-- insert data
insert into tab1 values (encrypt_aes ('WXY'));

-- call procedure
```

Output from the SET EXPLAIN statement always displays the *password* and *hint* parameters as `xxxxxx`, rather than displaying actual *password* or *hint* values.

## SET ENVIRONMENT statement

Use the SET ENVIRONMENT statement to specify settings for session environment variables that can affect how queries are executed in the same routine, or other operations in the current user session. For some options, the session variable overrides default behavior that is set by a configuration parameter or by an environment variable of the client or of the database server.

This statement is an extension to the ISO/ANSI standard for the SQL language.

| Element        | Description   | Restrictions   | Syntax                                     |
|----------------|---|--|--|
| <i>char</i>    | A single character to set as the default escape character in <code>LIKE</code> or <code>MATCHES</code> operands in the session  | Must be a single-byte character  | <a href="#">Quoted String on page 1424</a> |
| <i>grid</i>    | Name of default existing grid for subsequent queries with no explicit GRID clause   | Must exist, and be defined by the <code>cdr</code> define grid command   | <a href="#">Quoted String on page 1424</a> |
| <i>integer</i> | See <a href="#">Options supporting ranges of integer values on page 904</a> for the semantics and ranges of <i>integer</i> settings among session environment options | Must be valid for the specified session environment option               | <a href="#">Quoted String on page 1424</a> |
| <i>region</i>  | Default region within an existing grid for subsequent queries with no explicit GRID clause  | Must exist, and be defined by the <code>cdr</code> define region command | <a href="#">Quoted String on page 1424</a> |

## Usage

The SET ENVIRONMENT statement can set session environment variables that affect queries or resource use during the current session. Many of its options can override the explicit or default value of an environment variable or of a configuration parameter.

For example, the following statement enables external directives during the current session:

```
SET ENVIRONMENT EXTDIRECTIVES "1";
```

This instructs the query optimizer to consider external optimizer directives in the **sysdirectives** system catalog table, if any are registered there, when choosing query execution plans. The database server complies, even if this conflicts with settings of the **EXT\_DIRECTIVES** configuration parameter and **IFX\_EXTDIRECTIVES** environment variable that disable external directives. If several mechanisms can define database server behavior that a session environment variable can also control, the SET ENVIRONMENT setting generally takes precedence over the following settings during the current session:

- conflicting system default values,
- conflicting explicit or default settings of configuration parameters,
- conflicting explicit or default settings of client or server environment variables.

## The scope of session environment variables

As the term *session environment variable* implies, most options influence the server only during the same session that issues the SET ENVIRONMENT statement. When that session terminates, permanent database objects that it created or modified persist, but other sessions follow the system default behavior, unless they issue their own SET ENVIRONMENT statements. (But options set by a **sysdbopen** routine are restored in future sessions, if the same **sysdbopen** routine runs.)

For some options, however, a setting persists only while the routine that set it is running, rather than until the session ends. For example,

```
SET ENVIRONMENT OPTCOMPIND '2';
```

instructs the query optimizer to use cost as the basis for subsequent join plans during the session, rather than favoring nested-loop joins. The setting takes effect even if this behavior conflicts with the current `0` or `1` setting of the **OPTCOMPIND** configuration parameter, or of the environment variable with the same name. Concurrent sessions are not affected by SET ENVIRONMENT OPTCOMPIND statements in UDRs of another session. See also the [OPTCOMPIND session environment option on page 942](#).

SQL syntax in some DDL or DML statements can override a session environment variable setting for some database objects, as in this example, where **unseen** is a fragmented table:

```
SET ENVIRONMENT AUTO_STAT_MODE OFF;
UPDATE STATISTICS HIGH FOR TABLE unseen AUTO;
```

The SET ENVIRONMENT statement instructs the server to ignore `STATCHANGE` criteria for recalculating only stale distribution statistics, so that by default, statistics must be recalculated for all fragments. The `AUTO` keyword, however, instructs the server to disregard the `OFF` setting of `AUTO_STAT_MODE`. This has higher precedence than SET ENVIRONMENT, placing the UPDATE STATISTICS statement outside the scope of the session environment variable. Statistics for fragment of the **unseen** table will be recalculated selectively, without recalculating any fragments with HIGH mode statistics that are not stale. See also [AUTO\\_STAT\\_MODE session environment option on page 912](#) and [STATCHANGE session environment option on page 952](#).

Similarly, this SET ENVIRONMENT statement makes automatic location and implicit fragmentation the default storage option for tables created in the session:

```
SET ENVIRONMENT AUTOLOCATE "2";
SELECT sname FROM state WHERE LENGTH(sname) < 7
INTO RAW reSuIt IN dbSp07; --IN clause blocks AUTOLOCATE
```

The IN clause prevents automatic location for the two fragments that the AUTOLOCATE setting of `"2"` implies. Rather than storing result table fragments in dbspaces automatically chosen by the database server, this query creates a nonfragmented **reSuIt** table in the **dbSp07** dbspace. This explicit Storage Options syntax excludes this SELECT example from the scope of the AUTOLOCATE setting, which can take effect only for new tables that are created during the session with syntax satisfying the automatic location requirements. For more information, see [AUTOLOCATE session environment option on page 906](#).

### Effects of SET ENVIRONMENT options on concurrent sessions

For some session environment variables, however, SET ENVIRONMENT statements in one session can affect the server behavior in concurrent sessions. For example, suppose a nonadministrative user needs to limit how many ROW locks are available to a session by setting the `IFX_SESSION_LIMIT_LOCKS` option below the explicit or default **SESSION\_LIMIT\_LOCKS** configuration parameter value. A statement like this can accomplish that goal:

```
SET ENVIRONMENT IFX_SESSION_LIMIT_LOCKS "1700";
```

Until the session ends, users in other sessions who do not hold administrative privileges can hold no more than 1700 locks. The `IFX_SESSION_LIMIT_LOCKS` setting has no effect on administrators like user **informix** or DBSA users. See also [IFX\\_SESSION\\_LIMIT\\_LOCKS session environment option on page 931](#).

The `FORCE_DDL_EXEC` session environment option also can affect concurrent transactions, but in an asymmetrical way. The effects of enabling this option can force out transactions in concurrent sessions that hold locks on tables that the enabling session references in ALTER FRAGMENT ON TABLE statements. For more information, see [FORCE\\_DDL\\_EXEC session environment option on page 921](#).

## Options supporting ranges of integer values

The following SET ENVIRONMENT session environment variables can be set to values with delimited *integer* settings. This table identifies those options, their ranges, and effects of their *integer* settings.

**Table 13. Effects of session environment options that accept *integer* values**

| Environment option                            | Integer range                           | Effect   |
|---|---|--|
| <b>AUTOLOCATE</b>                             | '1' <i>integer</i> '32'                 | Enables automatic storage location of tables, and allocates that number of initial round-robin fragments. A setting of '0' disables this storage automation.   |
| <b>AUTO_READAHEAD</b>                         | '4' <i>integer</i> '4096'               | For the optional second parameter, a value in the range '4'-'4096' specifies how many pages to include in automatic read-ahead requests. If omitted, the default is '128'.   |
| <b>BOUND_IMPL_PDQ</b> and <b>IMPLICIT_PDQ</b> | '1' <i>integer</i> '100'                | To use explicit <b>PDQPRIORITY</b> environment variable settings as the upper bound (and optional lower bound) of memory granted to a query, set the <b>BOUND_IMPL_PDQ</b> option. The database server scales its <b>PDQPRIORITY</b> estimate by the specified <b>IMPLICIT_PDQ</b> value.  |
| <b>FORCE_DDL_EXEC</b>                         | '2' <i>integer</i>                      | Limits the number of seconds to allow the server to force out transactions that are open or hold a lock on the target table of an ALTER FRAGMENT ON TABLE statement, until the server obtains a lock and exclusive access on the table. If any of those transactions persist beyond the specified time limit, the server stops attempting to force out the transactions. |
| <b>IFX_SESSION_LIMIT_LOCKS</b>                | '500' <i>integer</i>                    | The maximum number of locks for users who are not administrators. This limit cannot exceed the <b>SESSION_LIMIT_LOCKS</b> configuration parameter value. If this parameter is not set, the default value of 2147483647 is the upper limit for <i>integer</i> .   |
| <b>INFORMIXCONTIME</b>                        | <b>SESSION_LIMIT_LOCKS</b><br>'integer' | Limits for how many seconds the CONNECT statement attempts to establish a connection to a database server. A setting of '0' defaults to the <b>INFORMIXCONTIME</b> configuration parameter value.  |
| <b>INFORMIXCONRETRY</b>                       | '1' <i>integer</i>                      | Sets the maximum number of additional connection attempts by the CONNECT statement after the first connection failure. A connection attempt can end sooner than the specified value, if the <b>INFORMIXCONTIME</b> value is exceeded.  |

**Table 13. Effects of session environment options that accept *integer* values**

(continued)

| Environment option   | Integer range             | Effect  |
|----------------------|---------------------------|---|
| <b>OPTCOMPIND</b>    | '0', '1', or '2'          | <p>Prioritizes available execution plans for join queries:</p> <ul style="list-style-type: none"> <li>• <b>AUTO_READAHEAD</b> favors nested-loop joins</li> <li>• '1' bases the decision on the isolation level</li> <li>• '2' favors the lowest cost.</li> </ul> |
| <b>QUERY_TIMEOUT</b> | '0' ≤ 'integer' ≤ '10000' | <p>Sets the maximum clock time, in seconds, that a query may run before it is internally interrupted. This timeout does not affect DML or DDL statements, or administration commands. A setting of '0' effectively disables the timeout.</p>                      |
| <b>STATCHANGE</b>    | '1' 'integer' '100'       | <p>Sets a percentage of rows that were modified since distribution statistics were calculated. The server uses this as a data-change threshold for UPDATE STATISTICS operations in automatic mode on tables or fragments.</p>                                     |

In addition to the session environment variables that accept as their setting a cardinal number in the integer ranges 1 listed here, the following session environment variables support as their setting the values '1' and '0', encoding these Boolean semantics:

'1'

Enables the database server behavior associated with the session environment variable

'0'

Disables the database server behavior associated with the session environment variable.

These are the SET ENVIRONMENT options that accept '1' or '0' as their setting:

- **AUTO\_READAHEAD,**
- **EXTDIRECTIVES,**
- **FORCE\_DDL\_EXEC,**
- **IFX\_AUTO\_REPREPARE,**
- **IFX\_BATCHEDREAD\_INDEX,**
- **IFX\_BATCHEDREAD\_TABLE,**
- **NOVALIDATE,**
- **USTLOW\_SAMPLE.**

### The OFF, ON, and DEFAULT keyword options

The following keywords have similar effects for several session environment options:

- `OFF` disables the specified option
- `ON` enables the option
- `DEFAULT` sets the option to its default value.

The arguments that follow the option name depend on the syntax of the option. The option name and its `ON`, `OFF`, and `DEFAULT` keywords do not require quotation mark delimiters, and are not case-sensitive. All other arguments must be enclosed between single ( `'` ) or double ( `"` ) quotation marks. If a quoted string is a valid argument for a session environment option, the argument is not case-sensitive. The `SET ENVIRONMENT` statement syntax diagram is simplified, by showing only single ( `'` ) quotation mark around syntax tokens for which double ( `"` ) quotation marks are also valid as delimiters. As in all SQL operations, both delimiters of a string value (or of an empty string) must be identical.

If you specify an unsupported session environment option name, error `-19840` is returned. If you specify an unsupported *integer* or digit value as the setting for a valid environment option, an option-specific error is returned (for example, error `-19843`, `Invalid IFX_AUTO_REPREPARE value specified`).

## AUTOLOCATE session environment option

Use the `AUTOLOCATE` environment option of the `SET ENVIRONMENT` statement to enable or disable the automatic location of databases, indexes, and permanent tables.

Setting this session environment option to an integer value greater than `'0'` but less than `'33'` also enables round-robin fragmentation as the default distributed storage for new tables created during the current session, using the `AUTOLOCATE` setting as the initially allocated number of fragments.

The `SET ENVIRONMENT AUTOLOCATE` statement of SQL supports the following syntax:

`AUTOLOCATE` environment option

**SET ENVIRONMENT AUTOLOCATE**

`'0'`

`'integer'`

| Element              | Description   | Restrictions                                   | Syntax                                     |
|----------------------|---|--|--|
| <code>integer</code> | Nonnegative integer that defines how many round-robin fragments to allocate initially | Must be in the range 1 <code>integer</code> 32 | <a href="#">Quoted String on page 1424</a> |

## Usage

The AUTOLOCATE session environment option can have the following values:

```
'0' or "0"
```

Disables automatic location and implicit fragmentation during the current session.

```
'integer' or "integer" where 1 integer 32
```

Enables automatic location and round-robin fragmentation. The *integer* value defines how many round-robin fragments to initially allocate to each permanent table created in the current session.

The current setting of the AUTOLOCATE option overrides the value of the **AUTOLOCATE** configuration parameter during the current session.

### Effect of automatic location on the CREATE DATABASE statement

The setting of the AUTOLOCATE session environment option affects CREATE DATABASE statements that include no IN clause list of dbspaces.

Suppose that automatic location is disabled, because the **AUTOLOCATE** configuration parameter is set to 0. You can issue the following statement to enable automatic location and implicit fragmentation in the current session:

```
SET ENVIRONMENT AUTOLOCATE '2';
```

The new AUTOLOCATE session environment setting of '2' has the following effect during the session on how the database server processes subsequent CREATE DATABASE statements in which the IN clause is omitted, such as the following example:

```
CREATE DATABASE IF NOT EXISTS stores_new
WITH LOG NLSCASE SENSITIVE;
```

- The **stores\_new** database will not be created in the **root** dbspace, if a noncritical dbspace is available.
- Dbspaces with the smallest page size will be favored over those with larger pages.
- Dbspaces with the most free space will be favored.
- Dbspaces with extendable chunks will be favored.

If the **AUTOLOCATE** configuration parameter has a valid setting greater than 0, the above criteria for automatically choosing a dbspace are already in effect.

The enabled AUTOLOCATE session environment setting has no effect, however, on the following CREATE DATABASE statement, because the dbspaces specified in the IN clause overrides automatic selection of dbspaces by the database server for the **stores\_newer** database:

```
CREATE DATABASE IF NOT EXISTS stores_newer IN dbsp04, dbsp05
WITH LOG NLSCASE SENSITIVE;
```

Databases like **stores\_newer** that are created without automatic location can store tables and indexes whose storage location and fragmentation are based on the AUTOLOCATE session environment setting. For example, any permanent table or index that is created in the **stores\_newer** database during a session with the AUTOLOCATE session environment option enabled can use implicit round-robin fragmentation for fragments in the **dbsp04** and **dbsp05** dbspaces, if the table or index is created without the Storage Options clause.

### Effect on CREATE TABLE statements

The same `SET ENVIRONMENT AUTOLOCATE '2'` example has the following effect during the session on CREATE TABLE statements that omit the FIRST EXTENT and Storage Options clauses:

- The database server implicitly uses round-robin distributed storage for each permanent table that is created without a Storage Options clause, allocating two fragments, as specified by the AUTOLOCATE session environment setting.
- The dbspaces that store those fragments will be chosen automatically, based on the same criteria identified above for the CREATE DATABASE statement.

### Effect on CREATE INDEX statements

The same `SET ENVIRONMENT AUTOLOCATE '2'` example has the following effect during the session on CREATE INDEX statements when the Storage Options clause is omitted:

- The database creates a nonfragmented index by default in a dbspace chosen by the server, based on the above criteria. The same index will also store index-key information about rows in any additional table fragments that the database creates automatically, if the storage capacity limit or the maximum number of rows is exceeded for both of the initially allocated table fragments.
- You cannot apply the `IN TABLE` storage option of the CREATE INDEX statement to indexes on tables that are implicitly fragmented by the SET ENVIRONMENT AUTOLOCATE session environment option.

### Effect on permanent result tables of SELECT statements

The `SET ENVIRONMENT AUTOLOCATE '2'` example also applies automatic storage and implicit fragmentation to SELECT statements that use the `INTO STANDARD` or `INTO RAW` keywords, with no Storage Options clause, to store the result of a query in a new permanent table, as in the following query:

```
SELECT col1::INT fcol1, col2
FROM tab1 INTO STANDARD MyResultTab;
```

Because the AUTOLOCATE session environment setting is `'2'`, the database server automatically allocates two fragments for the **MyResultTab** permanent table that the SELECT statement created.

The AUTOLOCATE setting has no effect, however, on result tables created with the `INTO TEMP` or `INTO EXTERNAL` keyword options, or on result tables created with a Storage Options clause.

### Effect on other DML operations that insert rows

During the same session, the `SET ENVIRONMENT AUTOLOCATE '2'` example has the following effects on INSERT, LOAD, and MERGE statements that insert new rows into a table that was created with implicit fragmentation. When rows are inserted, the fragment with the fewest rows is favored until all fragments contain the same number of rows. But if the DML operation attempts to insert more rows than can fit in the existing fragments, or attempts to insert rows beyond the maximum number of rows that a fragment can contain, the database server takes the following actions:

- It creates a new round-robin fragment of the same page size as the original fragments, allocating this in a dbspace that has enough free pages. As in the case of CREATE DATABASE, if noncritical dbspaces are available, the database server does not choose critical dbspaces.
- After the new fragment is automatically attached to the table, the database server resumes inserting rows for the current INSERT, LOAD, or MERGE operation.

Any other *integer* setting for AUTOLOCATE within the range from "1" to "32" has the effects described above, but for *integer* initially allocated fragments. For example, the following statement instructs the database server to initially allocate 9 round-robin fragments to each new permanent table that uses automatic location and implicit fragmentation:

```
SET ENVIRONMENT AUTOLOCATE '9';
```

The next example enables automatic location and allocates a single initial fragment.

```
SET ENVIRONMENT AUTOLOCATE '1';
```

The fragment is initially empty, but if rows are inserted into the table, all are inserted into that fragment, because no other exists. Tables created in the session with implicit fragmentation can be referenced by the ALTER FRAGMENT statement, despite their superficial resemblance to nonfragmented tables. When no additional rows can be inserted into the original fragment, the database server automatically attaches a new round-robin fragment to the table.

See also the *IBM® Informix® Administrator's Reference* for information about how to run admin() and task() SQL administration API commands with one of the autolocate database arguments to manage the list of dbspaces that can store table fragments created with automatic location enabled by the AUTOLOCATE environment option or by the **AUTOLOCATE** configuration parameter.

### Disabling automatic location and implicit fragmentation

To disable automatic location and default round-robin fragmentation for the current session, run the following statement:

```
SET ENVIRONMENT AUTOLOCATE '0';
```

This setting only affects databases, indexes, and permanent tables that are created by subsequent DDL operations in the current session. Other sessions follow the behavior that corresponds to the **AUTOLOCATE** configuration parameter setting, or to SET ENVIRONMENT AUTOLOCATE statements issued in those sessions.

When automatic location is not in effect, the database server replaces the behavior described above with the following legacy behavior of Informix releases earlier than 12.10.xC3:

- Databases are created by default in the **root** dbspace, or in the dbspace that the IN clause of the CREATE DATABASE statement specifies,
- Tables are created without implicit fragmentation, and stored according to the default or explicit Storage Options clauses of the CREATE TABLE, ALTER TABLE, and ALTER FRAGMENT statements.
- New round-robin fragments are not created automatically when all existing fragments of the table are at their limit for storage size or for the number of rows in a fragment.

## AUTO\_READAHEAD session environment option

Use the AUTO\_READAHEAD environment option to change the automatic read-ahead mode, the batch size, the threshold, or to disable automatic read-ahead operations for the current session.

The AUTO\_READAHEAD session environment option has this syntax:

```
|--SET ENVIRONMENT AUTO_READAHEAD -'--+0+---+-----+---+-----+---+' |
                                     +1+  ',pages'  ',threshold'
                                     '2'
```

| Element          | Description   | Restrictions   | Syntax                                      |
|------------------|---|--|---|
| <i>pages</i>     | Number of data pages to read ahead                          | Must be an integer in the range <code>4 pages 4096</code>    | <a href="#">Literal Number on page 1419</a> |
| <i>threshold</i> | Percentage of unprocessed pages that will trigger next read | Must be an integer in the range <code>1 threshold 100</code> | <a href="#">Literal Number on page 1419</a> |

### Usage

The SET ENVIRONMENT AUTO\_READAHEAD statement of SQL accepts up to three values as its automatic read-ahead setting:

- A required *mode* setting, encoded as a digit in the range `0 mode 2`
- An optional *pages* setting, encoded as an integer in the range `4 pages 4096`.
- An optional *threshold* setting, encoded as an integer in the range `1 threshold 100`.

### Setting the mode to aggressive, standard, or disabled

You can change the automatic read-ahead mode for the current session by specifying one of the following values as the first AUTO\_READAHEAD parameter:

**0**

Disable automatic read-ahead requests.

**1**

Enable automatic read-ahead requests in the standard mode. The server will automatically process read-ahead requests only when a query waits on I/O.

**2**

Enable automatic read-ahead requests in the aggressive mode. The server will automatically process read-ahead requests at the start of the query, and continuously through the duration of the query.

The value that you specify for the *mode* overrides the setting of the **AUTO\_READAHEAD** configuration parameter for the session.

This is the descending order of precedence (highest to lowest) among methods for setting automatic read-ahead:

- The SET ENVIRONMENT AUTO\_READAHEAD statement (for a session)
- The **AUTO\_READAHEAD** configuration parameter value of 1 or 2.
- If **AUTO\_READAHEAD** has no setting in the **onconfig** file, but the **AUTO\_TUNE** configuration parameter is set to 1, the server performs automatic read-ahead on 128 data pages, equivalent to the default *pages* value in the standard mode.

### Setting the number of pages to read ahead

Besides setting the automatic read-ahead mode, you can also optionally specify a *pages* value as the second AUTO\_READAHEAD parameter:

#### **pages**

Specifies the batch size in pages (as an integer in the range 4 *pages* 4096) read by the database server when it receives an automatic read-ahead request.

Use a comma (,) as the separator between the values of read-ahead *mode* and read-ahead *pages*.

The specified *pages* value overrides the explicit or default batch size setting of the **AUTO\_READAHEAD** configuration parameter for the current session.

If the SET ENVIRONMENT AUTO\_READAHEAD statement includes no second parameter, the batch size value defaults to the explicit **AUTO\_READAHEAD** configuration parameter setting, or to 128 pages, if that configuration parameter is not set.

### Setting the threshold

Besides setting the automatic read-ahead mode and the batch size, you can also optionally specify a *threshold* value as the third AUTO\_READAHEAD parameter:

#### **threshold**

Specifies the percentage (as an integer in the range  $1 \leq \textit{threshold} \leq 100$ ) of the current batch that will remain unprocessed when the next batch of pages is requested.

Use a comma (,) as the separator between the values of read-ahead *pages* and read-ahead *threshold*.

The specified *threshold* value overrides the explicit or default threshold setting of the **AUTO\_READAHEAD** configuration parameter for the current session.

If the SET ENVIRONMENT AUTO\_READAHEAD statement includes no third parameter, the threshold value defaults to the explicit **AUTO\_READAHEAD** configuration parameter setting, or to 50, if that configuration parameter is not set.

### Examples of setting AUTO\_READAHEAD

Note that the value in the statement must be quoted, either with single or double quotes.

This statement disables automatic read-ahead operations during the current session:

```
SET ENVIRONMENT AUTO_READAHEAD '0';
```

After a session completes the work in which you wanted automatic read-ahead disabled, the following statement restores automatic read-ahead in standard mode for subsequent operations that scan tables:

```
SET ENVIRONMENT AUTO_READAHEAD '1';
```

If a larger `AUTO_READAHEAD` *page* setting seems more efficient, the next example maintains the standard mode, but instructs the server to increase the batch size to 1024 for subsequent read-ahead requests:

```
SET ENVIRONMENT AUTO_READAHEAD '1,1024';
```

If a different *threshold* setting seems more efficient, the next example instructs the server to trigger the next read-ahead request when 30% of the current batch remains unprocessed. Since our batch size is 1000 in this case, the next batch will be requested when the reader has 300 pages to process:

```
SET ENVIRONMENT AUTO_READAHEAD '1,1000,30';
```

Generally, the standard mode (`AUTO_READAHEAD = 1`) is appropriate in typical production environments, even for cached environments, but the `SET ENVIRONMENT AUTO_READAHEAD` statement enables you to take action in contexts where the efficiency of specific scans might benefit from modifying the read-ahead behavior.

The following example enables automatic read-ahead in aggressive mode, but accepts the default number of read-ahead pages and the threshold:

```
SET ENVIRONMENT AUTO_READAHEAD '2';
```

Use aggressive read-ahead operations only in situations in which you tested both settings and know that aggressive read-ahead operations are more effective. Do not use aggressive read-ahead operations if you are not sure that they are more effective.

For scans that might turn read-ahead operations off and on because the scan encounters pockets of cached data, aggressive mode read-ahead operations do not turn off read-ahead operations.

---

## AUTO\_STAT\_MODE session environment option

Use the `AUTO_STAT_MODE` environment option to enable or disable an automatic mode for `UPDATE STATISTICS` operations on column distribution statistics during the current session. In automatic mode, the user can define a minimum data change threshold as a property of the table. The database server refreshes statistics on the table, its indexes, and on table and index fragments selectively, only if the data has changed in a percentage of rows beyond that threshold since the distribution statistics were last calculated.

The `AUTO_STAT_MODE` session environment option has this syntax:

`AUTO_STAT_MODE` environment option

```
SET ENVIRONMENT AUTO_STAT_MODE
```

```
ON OFF
```

### Usage

Distribution statistics are used by the query optimizer to identify efficient execution plans for DML operations. Because calculating statistics for a large table is a resource-intensive operation, however, recalculating distributions that have not substantially changed from their current values in the system catalog degrades the performance of the database server, compared to a more efficient allocation of system resources.

The value that the `SET ENVIRONMENT AUTO_STAT_MODE` statement specifies can enable or disable the automatic identification and recalculation of stale column distribution statistics:

**ON**

Automatic `UPDATE STATISTICS` mode is enabled, and only stale statistics are automatically recalculated.

**OFF**

Automatic mode is disabled and `UPDATE STATISTICS` operations recalculate both stale and current statistics.

Automatic mode has no effect on routine statistics, or on `UPDATE STATISTICS` statements that include the `FORCE` keyword.

When automatic `UPDATE STATISTICS` mode is enabled, the `UPDATE STATISTICS` statement selectively refreshes only the table, column, and index data distribution statistics that it identifies as stale or missing. The user can specify the minimum change threshold as a table attribute when the table is created or altered. The value of this attribute overrides the explicit or default setting of the **STATCHANGE** configuration parameter.

The `SET ENVIRONMENT STATCHANGE` statement similarly overrides the **STATCHANGE** configuration parameter setting for the current session. If no `STATCHANGE` threshold is explicitly set, the system default threshold (of at least 10 percent of the rows changed since statistics were last calculated) defines stale data distributions when the automatic `UPDATE STATISTICS` mode is enabled.

When automatic mode is disabled, the database server does not consider any user-defined or default threshold for stale statistics when the `UPDATE STATISTICS` statement recalculates distribution statistic. In nonautomatic mode (or when you include the `FORCE` keyword in the `UPDATE STATISTICS` statement), the database server drops and recalculates the statistics for all of the specified tables and indexes, without reference to any previously calculated data distributions.

The automatic mode for `UPDATE STATISTICS` requires all of the fragments of a table to maintain the distribution of a column at the same resolution. This implies that consecutive `UPDATE STATISTICS` operations with a resolution different from what was used for creating the current column distribution in the system catalog forces a refresh of all column distributions for all fragments. If no resolution is specified, the database server uses the one that is stored with the distribution, rather than the default resolution of 2.5.

Only permanent tables are affected by automatic mode. The `AUTO_STAT_MODE` setting has no effect on temporary tables.

### The `AUTO_STAT_MODE` and **STATCHANGE** configuration parameters

The **AUTO\_STAT\_MODE** configuration parameter can specify a '1' or '0' global value for the automatic mode for `UPDATE STATISTICS` operations for all sessions of the database server, respectively encoding the enabled or disabled modes that this session environment option encodes as `ON` and `OFF`. You can use the `SET ENVIRONMENT AUTO_STAT_MODE` statement of SQL, however, to override the **AUTO\_STAT\_MODE** configuration parameter setting for the current session.

The **STATCHANGE** configuration parameter can specify a positive integer as a global percentage of the change threshold to define stale data distributions. When the automatic mode for `UPDATE STATISTICS` is enabled by the **AUTO\_STAT\_MODE** configuration parameter, this setting takes effect as the default change threshold for any table whose `STATCHANGE` table attribute is specified as `AUTO`, or that is `AUTO` by default. You can use the `SET ENVIRONMENT STATCHANGE` statement of SQL, however, to override the **STATCHANGE** configuration parameter setting for the current session.

### Examples of `SET ENVIRONMENT AUTO_STAT_MODE`

The following statement enables automatic mode for the current session:

```
SET ENVIRONMENT AUTO_STAT_MODE ON;
```

This overrides the setting of the **AUTO\_STAT\_MODE** configuration parameter, if it is 0, for the remainder of the current session, or until you reset the AUTO\_STAT\_MODE session environment variable.

If you are satisfied the behavior of UPDATE STATISTICS operations on distribution statistics without automatic mode, you can disable automatic mode for the session, as in this example:

```
SET ENVIRONMENT AUTO_STAT_MODE OFF;
```

### Statement-level granularity for setting automatic mode

For individual UPDATE STATISTICS FOR TABLE statements, appending the **AUTO** keyword can override the disabled AUTO\_STAT\_MODE status in contexts where automatic mode is appropriate, as in this example:

```
SET ENVIRONMENT AUTO_STAT_MODE OFF;
UPDATE STATISTICS MEDIUM FOR SPECIFIC TABLE orders AUTO;
```

Here the distribution statistics for the **orders** table will be refreshed (or for its fragments, if it has distributed storage with fragment-level STATCHANGE behavior) only for system catalog statistics of the **orders** table that qualify as stale. The scope of the **AUTO** keyword is restricted to the statement that includes it, rather than persisting. In contrast, the AUTO\_STAT\_MODE session environment variable remains disabled until the mode is reset or until the session ends.

Conversely, when automatic mode is enabled, you can temporarily disable it by including the **FORCE** keyword in individual UPDATE STATISTICS statements, so that the STATCHANGE status is disregarded and all table or fragment distribution statistics are refreshed while the statement is running, as in the next example:

```
SET ENVIRONMENT AUTO_STAT_MODE ON;
UPDATE STATISTICS MEDIUM FOR TABLE FORCE;
```

Because no table is specified, the scope of UPDATE STATISTICS in this example is every table in the database, but automatic mode remains in effect for any subsequent UPDATE STATISTICS operations that omit the **FORCE** keyword in the same session.

For more information about the **AUTO** keyword of UPDATE STATISTICS, and about its logical inverse, the **FORCE** keyword, see [Using the FORCE and AUTO keywords on page 1060](#).

For more information about the **AUTO\_STAT\_MODE** and **STATCHANGE** configuration parameters, see your *Informix® Administrator's Reference*.

For more information about the STATCHANGE table attribute, see the topics [Statistics options of the ALTER TABLE statement on page 163](#), [Statistics options of the CREATE TABLE statement on page 395](#), and [Performance considerations of UPDATE STATISTICS statements on page 1072](#).

### BOUND\_IMPL\_PDQ session environment option

You can set the BOUND\_IMPL\_PDQ session environment option to limit PDQ resource allocation. If the IMPLICIT\_PDQ session environment option is set to **ON** or to a positive integer value no greater than 100, you can use the BOUND\_IMPL\_PDQ environment option to specify that the allocated memory should be bounded by the current explicit **PDQPRIORITY** value or by a range.

The `IMPLICIT_PDQ` and the `BOUND_IMPL_PDQ` session environment options are available only on systems that support **PDQPRIORITY**. If `IMPLICIT_PDQ` is set to `OFF`, then the `BOUND_IMPL_PDQ` setting is ignored, and the server does not override the current **PDQPRIORITY** setting.

The `BOUND_IMPL_PDQ` session environment option has this syntax:

`BOUND_IMPL_PDQ` environment option

**SET ENVIRONMENT BOUND\_IMPL\_PDQ**

**OFF ON 'integer'**

| Element        | Description  | Restrictions  | Syntax                                     |
|----------------|--|---|--|
| <i>integer</i> | Nonnegative integer limiting the memory available to a query in the session as this percentage of the <b>PDQPRIORITY</b> value | Must be in the range <code>0 &lt; integer &lt; 101</code> | <a href="#">Quoted String on page 1424</a> |

## Usage

The `BOUND_IMPL_PDQ` environment option can be set to the following values, but its effects depend on the `IMPLICIT_PDQ` session environment option being enabled:

### OFF

No upper bound on implicit **PDQPRIORITY** calculation.

### ON

The server uses the explicitly specified **PDQPRIORITY** setting as the upper bound for calculating the implicit **PDQPRIORITY**.

### 'integer' or "integer"

The explicit **PDQPRIORITY** value is scaled by this percentage in the current session.

For example, you might execute the following statement to force the database server to use explicit **PDQPRIORITY** values as guidelines in allocating memory if the `IMPLICIT_PDQ` environment option is enabled for the current session:

```
SET ENVIRONMENT BOUND_IMPL_PDQ ON;
```

If you instead specify a positive integer in the range from 1 to 100, the explicit **PDQPRIORITY** value is scaled by that setting during the current session. The specified integer must be delimited by quotation marks, as in the following example, which specifies 75% of available PDQ memory as the upper bound:

```
SET ENVIRONMENT BOUND_IMPL_PDQ "75";
```

By default, `BOUND_IMPL_PDQ` is not enabled. When the `BOUND_IMPL_PDQ` session environment option is set to `ON` for the current session, you require the database server to use the explicit **PDQPRIORITY** setting as the upper bound for memory that can be allocated to a query. If you set both `IMPLICIT_PDQ` and `BOUND_IMPL_PDQ`, then the explicit **PDQPRIORITY** value determines the upper limit of memory that can be allocated to a query. If **PDQPRIORITY** is specified as a range, the database server grants memory within the range specified.

The following example disables `BOUND_IMPL_PDQ` in the current session, so that the server is not restricted in the proportion of the **PDQPRIORITY** setting that it can allocate to a query:

```
SET ENVIRONMENT BOUND_IMPL_PDQ OFF;
```

See also the *Informix® Performance Guide* discussion of parallel database query (PDQ).

## CLUSTER\_TXN\_SCOPE session environment option

When a client session in a high-availability cluster server issues a commit, the server blocks the current session until the committed transaction is applied in that session, or applied on a secondary server, or applied across the cluster, depending on the setting of the `CLUSTER_TXN_SCOPE` session environment option of the `SET ENVIRONMENT` statement.

The `CLUSTER_TXN_SCOPE` session environment option has this syntax:

`CLUSTER_TXN_SCOPE` session environment option

```
SET ENVIRONMENT CLUSTER_TXN_SCOPE '
```

```
CLUSTER SERVER SESSION DEFAULT
```

```
'
```

### Usage

In a cluster environment, this statement can apply a different transaction scope that overrides the setting of the `CLUSTER_TXN_SCOPE` configuration parameter for the current user session. It can also restore the effects of that `onconfig` file setting, after a `SET ENVIRONMENT` statement in the same session overrode the configuration parameter setting.

To use this transaction coordination feature, specify one of the following options, delimited by single ( `'` ) or double ( `"` ) quotation marks, immediately after the `SET ENVIRONMENT CLUSTER_TXN_SCOPE` keywords. The syntax diagram is simplified by omitting the `"` delimiters.

#### 'SESSION'

When a client session issues a commit, the database server blocks the session until the effects of the transaction commit are returned to that session. After control is returned to the session, other sessions at the same database server instance or on other database servers in the same cluster might be unaware of the transaction commit and of the effects of the transaction.

#### 'SERVER'

The database server reads the most recently committed version of the data if it encounters an exclusive lock while attempting to read a row in the Dirty Read or Read Uncommitted isolation level. This is the default behavior, unless the `CLUSTER_TXN_SCOPE` configuration parameter has a nondefault setting for your database server instance.

#### 'CLUSTER'

When a client session issues a commit, the database server blocks the session until the transaction is applied at all database servers in the high-availability cluster, excluding RS secondary servers that have the `DELAY_APPLY` or `STOP_APPLY` configuration parameters enabled. Other sessions at any database server in the high-availability cluster, excluding RS secondary servers that are using `DELAY_APPLY` or `DELAY_APPLY`, are aware of the transaction commit and the transaction's effects.

**'DEFAULT'**

The cluster transaction scope reverts to the **CLUSTER\_TXN\_SCOPE** configuration parameter setting in the `onconfig` file of the database server instance, if that parameter is set.

The **CLUSTER\_TXN\_SCOPE** setting affects sessions on read-only secondary servers and on updatable secondary servers. Transactions do not need to be applied on the RS secondary servers before client applications can receive commits.

**Examples of setting CLUSTER\_TXN\_SCOPE**

This statement sets the cluster as the scope of transaction coordination during the session:

```
SET ENVIRONMENT CLUSTER_TXN_SCOPE 'CLUSTER';
```

This setting minimizes the risk of transaction coordination failure, but it can increase the time required for the session to receive the transaction commit. For the session with this setting, after the primary server sends logical log buffers to the HDR secondary server, it returns control to the session, but the session does not receive a commit until the transaction is applied on all of the servers in the cluster.

The next example specifies the local database server as the scope of transaction coordination:

```
SET ENVIRONMENT CLUSTER_TXN_SCOPE 'SERVER';
```

The `'SERVER'` setting can reduce the risk of transaction coordination failure when different sessions on the same server are concurrently processing data in the same tables.

This example allows processing to resume after a transaction commit is returned to the current session:

```
SET ENVIRONMENT CLUSTER_TXN_SCOPE 'SESSION';
```

This setting might be appropriate if the session is accessing database objects that are unlikely to be referenced by concurrent sessions of the same server, or of other servers in the same cluster.

The following statement makes the value for the current setting match the **CLUSTER\_TXN\_SCOPE** configuration parameter setting of the local server instance:

```
SET ENVIRONMENT CLUSTER_TXN_SCOPE "DEFAULT";
```

If the **CLUSTER\_TXN\_SCOPE** configuration parameter setting for the server is `CLUSTER` or `SERVER`, then `"DEFAULT"` might have been a more appropriate **CLUSTER\_TXN\_SCOPE** session environment setting than the previous `"SESSION"` example, if transactions in concurrent sessions produce unexpected results.

**DEFAULTESCCHAR session environment option**

You can use the **DEFAULTESCCHAR** session environment option of the **SET ENVIRONMENT** statement to override the current default escape character within character-string operands of **LIKE** or **MATCHES** expressions during the current session.

**DEFAULTESCCHAR** environment option

**DEFAULTESCCHAR**

*'char'* **'NONE'**

| Element     | Description  | Restrictions  | Syntax  |
|-------------|--|---|---|
| <i>char</i> | A single character to set as the default escape character in LIKE or MATCHES expressions that include no ESCAPE clause | Must be a single-byte character, and must be delimited between single ( ' ) or double ( " ) quotation marks | <a href="#">Literal Number on page 1419</a><br><a href="#">asQuoted String on page 1424</a> |

## Usage

The DEFAULTESCCHAR session environment option can be set to one of the following values:

### 'char' or "char"

A single-byte ASCII character, delimited by single ( ' ) or double ( " ) quotation marks, that designates the default escape character for this session in LIKE or MATCHES expressions that include no ESCAPE clause.

### 'NONE' or "NONE"

A case-insensitive quoted string, indicating that in this session there is no default escape character for LIKE or MATCHES expressions that include no ESCAPE clause.

This is the descending order of precedence, from highest to lowest, among the methods for specifying an escape character for LIKE or MATCHES expressions:

- The character following the `ESCAPE` keyword of the LIKE or MATCHES expression
- The character following the `DEFAULTESCCHAR` keyword in the SET ENVIRONMENT statement (for the current session only)
- The character setting of the `DEFAULTESCCHAR` configuration parameter
- The system default backslash ( \ ) character.

## Setting a default escape character for the current session

An *escape character* instructs the SQL parser to interpret as a literal character (rather than as having special significance for the next character) any characters that can be wildcard characters. For example, default wildcards are

- % and \_ for operands of the LIKE operator,
- or \* and ^ for operands of the MATCHES operator.

In a LIKE or MATCHES expression, the escape character must immediately precede the character whose special significance is to be ignored.

For LIKE or MATCHES expressions in subsequent DML statements in the same session, the *escape character* value defined by the SET ENVIRONMENT DEFAULTESCCHAR statement overrides the setting of the `DEFAULTESCCHAR` configuration parameter. SET ENVIRONMENT DEFAULTESCCHAR statements in the current session, however, have no effect on how the database server evaluates LIKE or MATCHES expressions in other sessions, which can use the system default escape character in the `onconfig` file for LIKE or MATCHES expressions that include no ESCAPE clause, or can use a different setting of the DEFAULTESCCHAR option, if data records that those sessions process require a different escape character.

For example, in subsequent LIKE and MATCHES expressions in the same session that include no ESCAPE clause, the following statement makes '#' the default escape character:

```
SET ENVIRONMENT DEFAULTESCCHAR '#';
```

In the following WHERE clause with a LIKE expression, the previous SET ENVIRONMENT statement causes the SQL parser to interpret the three backslash ( \ ) symbols as literal characters in the file path, rather than as escape characters:

```
SELECT pathname FROM OldFiles2014
WHERE pathname LIKE 'C:#\user#\argos#\collars';
```

### Setting the DEFAULTESCCHAR to 'NONE'

To treat as a literal character the system default escape character ( \ ), and the default escape character set by the **DEFAULTESCCHAR** configuration parameter, and any session default escape character previously set by SET ENVIRONMENT DEFAULTESCCHAR in the current session, you can specify 'NONE' as the setting of the DEFAULTESCCHAR option:

```
SET ENVIRONMENT DEFAULTESCCHAR 'NONE';
```

When the 'NONE' setting is in effect, the database server has the following behavior when evaluating LIKE or MATCHES expressions during the session:

- In character-string operands of LIKE or MATCHES expressions, any escape character that an SQL statement uses to mark a wildcard symbol as a literal character must be defined in the ESCAPE clause of the same LIKE or MATCHES expression.
- LIKE or MATCHES expressions that include no ESCAPE clause must prefix wildcard characters that are used as literals with the default escape characters of the LIKE or MATCHES operators, or with the backslash ( \ ) character.
- In LIKE or MATCHES expressions, any other escape character that the **DEFAULTESCCHAR** configuration parameter defines in the ONCONFIG file is treated as a literal character, rather than as an escape character.

Only LIKE or MATCHES expressions that include no ESCAPE clause are affected by the DEFAULTESCCHAR session environment setting. For more information about escape characters in LIKE or MATCHES expressions, see the topics [ESCAPE with LIKE on page 1157](#) and [ESCAPE with MATCHES on page 1157](#).

## EXTDIRECTIVES session environment option

You can use the EXTDIRECTIVES environment option of the SET ENVIRONMENT statement to enable or disable external optimizer directives during the current session.

The EXTDIRECTIVES session environment option has this syntax:

```
EXTDIRECTIVES environment option
```

**EXTDIRECTIVES**

**OFF '0' ON '1'**

**DEFAULT**

## Usage

The setting that you specify for `EXTDIRECTIVES` session environment option can override the settings of both the `IFX_EXTDIRECTIVES` environment variable and of the `EXT_DIRECTIVES` configuration parameter in the `ONCONFIG` file for enabling or disabling external optimizer directives in the current session. Other user sessions are not affected.

To set the `EXTDIRECTIVES` session environment variable, specify one of these values:

### '1' OR ON

Enables external optimizer directives. During the current session, this setting overrides whatever values are set in the client-side `IFX_EXTDIRECTIVES` environment variable or in the `EXT_DIRECTIVES` configuration parameter.

### '0' OR OFF

Disables external optimizer directives. During the current session, this setting overrides whatever values are set in the client-side `IFX_EXTDIRECTIVES` environment variable or in the `EXT_DIRECTIVES` configuration parameter.

### DEFAULT

Enables during the current session a default value that depends on the settings of the client-side `IFX_EXTDIRECTIVES` environment variable, if that is set, and on the `EXT_DIRECTIVES` configuration parameter, if that is set, as described immediately below in this topic.

## The DEFAULT setting

If you or the `sysdbopen` routine used the `SET ENVIRONMENT EXTDIRECTIVES` statement earlier in the same session to enable or to disable external optimizer directives, the `SET ENVIRONMENT EXTDIRECTIVES DEFAULT` statement restores the external optimizer directives behavior of the database server to its default state.

After the `DEFAULT` setting takes effect for the session, whether the query execution optimizer is influenced by external directives depends on the settings of the `EXT_DIRECTIVES` configuration parameter and of the client-side `IFX_EXTDIRECTIVES` environment variable.

- When the `EXTDIRECTIVES` option of the `SET ENVIRONMENT` statement is set to `DEFAULT`, and `EXT_DIRECTIVES` and `IFX_EXTDIRECTIVES` are both enabled, then external optimizer directives are enabled during the current session.
- When `EXTDIRECTIVES` is set to `DEFAULT`, and `EXT_DIRECTIVES` and `IFX_EXTDIRECTIVES` are both disabled, then external optimizer directives are disabled during the current session.
- If `EXTDIRECTIVES` is set to `DEFAULT`, but `EXT_DIRECTIVES` and `IFX_EXTDIRECTIVES` have conflicting settings, so that one of them is set to enabled, but the other is set to disabled, then the database server behaves according to these rules:
  - if `EXT_DIRECTIVES` is set to `0` (or if it has no setting), then by default, external directives are disabled, even if `IFX_EXTDIRECTIVES` is enabled.
  - if `EXT_DIRECTIVES` is set to `1`, external directives are disabled if `IFX_EXTDIRECTIVES` is set to disabled.
  - if `EXT_DIRECTIVES` is set to `1`, external directives are enabled if `IFX_EXTDIRECTIVES` is set to enabled.
  - if `EXT_DIRECTIVES` is set to `2`, then external directives are enabled, regardless of the `IFX_EXTDIRECTIVES` setting.

If no SET ENVIRONMENT EXTDIRECTIVES statement was previously issued in the current session, it is generally not necessary to run the SET ENVIRONMENT EXTDIRECTIVES DEFAULT statement. Unless the **EXT\_DIRECTIVES** configuration parameter has been reset since the session began, the database server is already in its default state for processing external optimizer directives.

### Examples of enabling or disabling external directives

The following statement enables external directives in subsequent queries executed in the current session:

```
SET ENVIRONMENT EXTDIRECTIVES "1";
```

The following statement has the same effect:

```
SET ENVIRONMENT EXTDIRECTIVES ON;
```

In both cases, the database server ignores the **EXT\_DIRECTIVES** and **IFX\_EXTDIRECTIVES** settings, but those settings might affect queries in other concurrent sessions,

Both of the following statements disable external directives in subsequent queries in the current session:

```
SET ENVIRONMENT EXTDIRECTIVES OFF;
```

```
SET ENVIRONMENT EXTDIRECTIVES "0";
```

The following statement allows processing of external directives in subsequent queries of the current session to be determined by the **EXT\_DIRECTIVES** and **IFX\_EXTDIRECTIVES** settings, as described earlier in this topic:

```
SET ENVIRONMENT EXTDIRECTIVES DEFAULT;
```

[SAVE EXTERNAL DIRECTIVES statement on page 762](#) for a table that identifies the **DEFAULT** behavior of the database server for external optimizer directives for all possible combinations of **EXT\_DIRECTIVES** configuration parameter settings and **IFX\_EXTDIRECTIVES** environment variable settings.

### Related information about external optimizer directives

For information on how to define external optimizer directives and how to save them in the **sysdirectives** table of the system catalog, see the same [SAVE EXTERNAL DIRECTIVES statement on page 762](#) topic. For more information about the **EXT\_DIRECTIVES** configuration parameter and the effects of its settings, see the HCL Informix® Administrator's Reference.

For more information about the **IFX\_EXTDIRECTIVES** environment variable, see the *Informix® Guide to SQL: Reference*, which also describes how the settings of the **EXT\_DIRECTIVES** configuration parameter and of the **IFX\_EXTDIRECTIVES** environment variable can jointly determine whether access to external directives is enabled or disabled for the query optimizer.

### FORCE\_DDL\_EXEC session environment option

Use the FORCE\_DDL\_EXEC session environment option of the SET ENVIRONMENT statement to force out other transactions that have opened or have locks on the tables involved in an ALTER FRAGMENT ON TABLE operation.

These are prerequisites for enabling the FORCE\_DDL\_EXEC session environment option:

- You must be user **informix** or have DBA privileges on the database.
- The database must be a logging database.

FORCE\_DDL\_EXEC session environment option has this syntax:

FORCE\_DDL\_EXEC session environment option

**SET ENVIRONMENT FORCE\_DDL\_EXEC**

**OFF '0'**

**ON '1'**

**'seconds'**

| Element        | Description   | Restrictions                         | Syntax                                     |
|----------------|---|--------------------------------------|--|
| <i>seconds</i> | Nonnegative integer, setting a limit in seconds on the time available for the server to force out transactions and obtain exclusive access to the table | Must be an integer greater than zero | <a href="#">Quoted String on page 1424</a> |

## Usage

The FORCE\_DDL\_EXEC option can have any of the following values:

### **ON or '1'**

This enables the server to force out transactions that are open or have a lock on the table when an ALTER FRAGMENT ON TABLE statement is issued until the server gets a lock and exclusive access on the table.

### **'seconds'**

Specifies a time interval, in units of seconds, to allow the server to force out transactions that are open or that hold a lock on the target table of an ALTER FRAGMENT ON TABLE statement, until the server obtains a lock and exclusive access on the table, or until the specified time limit occurs. If the server cannot force out transactions within the specified time interval, the server stops attempting to force out the transactions, and the ALTER FRAGMENT statement waits for the locks to be released when the concurrent transactions are committed or rolled back.

### **OFF or '0'**

Prevent the database server from forcing out transactions that are open or have a lock on the table when an ALTER FRAGMENT ON TABLE statement is issued. (This is the default behavior, unless a previous SET ENVIRONMENT FORCE\_DDL\_EXEC statement in the same session has enabled forcing out transactions during ALTER FRAGMENT ON TABLE statements.)

You must delimit the *seconds*, **1**, or **0** setting by single ( ' ) or double ( " ) quotation marks. The **ON** and **OFF** keywords are case insensitive.

**Important:** When you use the FORCE\_DDL\_EXEC environment option, also use the SET LOCK MODE TO WAIT statement to specify a period of time for the server to force out any transactions in order to get exclusive access and a lock. If you run

SET LOCK MODE TO WAIT without specifying an amount of time, the FORCE\_DDL\_EXEC option will not impact the ALTER FRAGMENT operation. For more information, see the [SET LOCK MODE statement on page 982](#).

When you enable the FORCE\_DDL\_EXEC environment option, the server supports multiple sessions performing ALTER FRAGMENT ON TABLE operations. If two sessions perform ALTER FRAGMENT ON TABLE on the same table when the FORCE\_DDL\_EXEC option is enabled, the second session receives an error. If another ALTER operation is occurring on the table, the ALTER FRAGMENT ON TABLE operation with an enabled FORCE\_DDL\_EXEC environment option will get an error.

Enabling this feature in sessions that issue ALTER FRAGMENT ON TABLE statements can avoid waiting for locks to be released. Effects on applications in other sessions where DDL statements access the same tables, however, can include closing their Update cursors, and rolling back their uncommitted transactions.

After you complete an ALTER FRAGMENT ON TABLE operation with the FORCE\_DDL\_EXEC environment option enabled, you can run the following statement to disable FORCE\_DDL\_EXEC environment option:

```
SET ENVIRONMENT FORCE_DDL_EXEC '0';
```

The **onshowaudit** utility displays an ALTER FRAGMENT event code (**ALFR**), which identifies ALTER FRAGMENT events that ran while the FORCE\_DDL\_EXEC environment option was enabled.

When the FORCE\_DDL\_EXEC environment option is enabled, the server also closes the hold cursors during rollback by the session that performs the ALTER FRAGMENT ON TABLE operation.

### Examples of setting FORCE\_DDL\_EXEC

Unlike most session environment options of the SET ENVIRONMENT statement, the effects of enabling the FORCE\_DDL\_EXEC option in a logged database can directly affect DDL operations on the same table in concurrent sessions,

- by requiring their transaction to commit within your SET LOCK MODE TO WAIT *interval* time limit,
- or by rolling back their transaction, if that provides you with exclusive access to the table within the *seconds* value of your SET ENVIRONMENT FORCE\_DDL\_EXEC statement, or when the FORCE\_DDL\_EXEC option is enabled with no time limit.

If the database server succeeds in rolling back a transaction in the other session, it issues the following error, regardless of the duration of the forced-out transaction:

```
-458 Long transaction aborted.
```

For example, the following SQL statements take these actions:

- Enable FORCE\_DDL\_EXEC for 240 seconds
- Wait up to 60 seconds for locks held by other sessions to be released
- Change the Rolling Window purge policy of the **window\_orders** table
- Disable the FORCE\_DDL\_EXEC environment option.

```
SET ENVIRONMENT FORCE_DDL_EXEC '240';
SET LOCK MODE TO WAIT 60;
ALTER FRAGMENT ON TABLE window_orders MODIFY INTERVAL
LIMIT TO 10 MiB DETACH INTERVAL ONLY;
SET ENVIRONMENT FORCE_DDL_EXEC OFF;
```

But if the SET LOCK MODE statement above had specified no limit

```
SET ENVIRONMENT FORCE_DDL_EXEC '240';
SET LOCK MODE TO WAIT;
```

then the `FORCE_DDL_EXEC` setting would have no effect, because the database server would have waited until no concurrent transactions held locks on the **window\_orders** table, which is the default behavior without `FORCE_DDL_EXEC` set.

The following statement enables the `FORCE_DDL_EXEC` environment option with no time limit during `ALTER FRAGMENT` operations:

```
SET ENVIRONMENT FORCE_DDL_EXEC '1';
```

## GRID\_NODE\_SKIP session environment option

Use the `GRID_NODE_SKIP` option of the `SET ENVIRONMENT` statement to define the behavior of the database server when a grid server within the grid or region that the query specifies is not available.

`GRID_NODE_SKIP` environment option

**SET ENVIRONMENT GRID\_NODE\_SKIP**

**ON**

**OFF DEFAULT**

### Usage

The `GRID_NODE_SKIP` session environment option can be set to any of three values:

#### ON

If a grid server within the specified grid or region is not available when the grid query attempts to retrieve qualifying rows from that node, an error is returned to the server that issued the grid query. That server continues processing the query by attempting to connect to the next server in the grid or region, unless the server whose results were skipped was last among the participating grid servers. In that case, the results from the available nodes are combined, and the logical `UNION` or `UNION ALL` from the results of the available grid servers is calculated by the server that issued the grid query.

#### DEFAULT

This setting specifies the default behavior. If a grid server within the specified grid or region is not available when the grid query attempts to retrieve qualifying rows from a database of that node, an error is returned to the server that issued the grid query, and the query fails.

#### OFF

This has the same effect as the explicit `DEFAULT` setting, as described above.

When the `SET ENVIRONMENT GRID_NODE_SKIP ON` statement is in effect for the current session, a grid query can return results when multiple grid servers are unavailable. The identity of a skipped grid server can be returned by executing the `ifx_gridquery_skipped_nodes()` function. Another function, `ifx_gridquery_skipped_node_count()`, can be called to detect how many nodes of the grid or region were skipped. For more information about these functions, see the .

Because a grid query is a dynamic UNION or UNION ALL combined query, the decision to skip a grid server occurs at the start of statement preparation, not when the statement is executed. The reason for this is that if information from the remote data dictionary cannot be obtained, then the SELECT statement cannot be prepared. Therefore, the database server that issues the grid query makes the decision to skip or not skip any unavailable grid servers prior to statement execution, if the GRID\_NODE\_SKIP session environment option is set to ON.

The GRID\_NODE\_SKIP setting has no effect outside a grid context.

### Examples of setting GRID\_NODE\_SKIP

From a session in a database of a grid server, the following statement prevents subsequent grid queries from failing with an error if any of the grid servers are unavailable when the grid or the region of the query:

```
SET ENVIRONMENT GRID_NODE_SKIP ON;
```

With the GRID\_NODE\_SKIP option enabled, the database server ignores any node which is not available when it executes a grid query, and returns qualifying rows from the participating grid servers.

The next example has the opposite effect, disabling the GRID\_NODE\_SKIP option:

```
SET ENVIRONMENT GRID_NODE_SKIP DEFAULT;
```

The following statement achieves the same effect as the `DEFAULT` setting, but with fewer keystrokes:

```
SET ENVIRONMENT GRID_NODE_SKIP OFF;
```

## HDR\_TXN\_SCOPE session environment option

Use the SET ENVIRONMENT HDR\_TXN\_SCOPE statement of SQL to control when a transaction commit is returned to a client application in a cluster environment.

The HDR\_TXN\_SCOPE session environment option has this syntax:

HDR\_TXN\_SCOPE session environment option

```
SET ENVIRONMENT HDR_TXN_SCOPE '
```

```
ASYNC NEAR_SYNC FULL_SYNC
```

```
;
```

### Usage

In a cluster environment, this statement can perform the following actions:

- Override the current setting of the HDR\_TXN\_SCOPE configuration parameter for the current user session.
- Restore the effects of that `onconfig` file setting after a previous SET ENVIRONMENT HDR\_TXN\_SCOPE statement in the same session overrode the configuration parameter setting.

To use this transaction synchronization feature, set the **DRINTERVAL** configuration parameter to 0, and then run a SET ENVIRONMENT statement that specifies one of the following options, delimited by single ( ' ) or double ( " ) quotation marks, immediately after the SET ENVIRONMENT HDR\_TXN\_SCOPE keywords. The syntax diagram is simplified by omitting the " delimiters.

#### 'ASYNC'

Asynchronous mode, where transactions do not require acknowledgement of being received or completed on the HDR secondary server before they can complete. System performance is best when a replication pair uses asynchronous mode, but if there is a server failure, data can be lost.

#### 'FULL\_SYNC'

Fully synchronous mode, where transactions require acknowledgement of completion on the HDR secondary server before they can complete. Data integrity is highest when a replication pair uses fully synchronous mode, but system performance can be negatively affected if client applications use unbuffered logging and have many small transactions.

#### 'NEAR\_SYNC'

Nearly synchronous mode, where transactions require acknowledgement of being received on the HDR secondary server before they can complete. Nearly synchronous mode can have better performance than fully synchronous mode and better data integrity than asynchronous mode. If used with unbuffered logging, SYNC mode, which is turned on when **DRINTERVAL** is set to -1, is the same as nearly synchronous mode.

When the **DRINTERVAL** configuration parameter is set to 0, the value of the HDR\_TXN\_SCOPE parameter determines the synchronization mode for HDR replication.

### Examples of setting HDR\_TXN\_SCOPE

To maintain safeguards against data loss, but avoid performance problems that are caused by client applications that perform many small transactions with unbuffered logging, you can enable nearly synchronous mode by running the following statement:

```
SET ENVIRONMENT HDR_TXN_SCOPE 'NEAR_SYNC' ;
```

With this setting, transactions require acknowledgement of completion on the HDR secondary server before they can complete.

When the **DRINTERVAL** configuration parameter is set to 0, the following statement supports asynchronous HDR replication in a session with buffered or unbuffered transaction logging:

```
SET ENVIRONMENT HDR_TXN_SCOPE 'ASYNC' ;
```

With this setting, transactions do not require acknowledgement of being received or completed on the HDR secondary server before they can complete.

When the **DRINTERVAL** configuration parameter is set to 0, the following statement supports fully synchronous HDR replication in a session with buffered or unbuffered transaction logging:

```
SET ENVIRONMENT HDR_TXN_SCOPE 'FULL_SYNC' ;
```

With this setting, transactions require acknowledgement of completion on the HDR secondary server before they can complete.

## IFX\_AUTO\_REPREPARE session environment option

Use the IFX\_AUTO\_REPREPARE session environment option to temporarily change the system-wide setting of the AUTO\_REPREPARE configuration parameter. The new setting is in effect for the remainder of the session or until you reset IFX\_AUTO\_REPREPARE for the session.

If IFX\_AUTO\_REPREPARE is enabled during table schema changes that do not require reissuing the DESCRIBE statement, the database server automatically identifies and reprepares prepared statements and reoptimizes SPL routines that reference the modified table. Enabling this option might also reduce the need to issue the PREPARE statement explicitly to reprepare prepared objects, or to issue the UPDATE STATISTICS FOR ROUTINE statement explicitly to reoptimize SPL routines.

While the IFX\_AUTO\_REPREPARE option is enabled, you can avoid -710 errors after some changes to the schema of a database table, such as adding an enabled index. However, enabling this option does not prevent -710 errors altogether. Error -710 might be issued when a cursor attempts to execute a prepared object, or when an SPL routine performs a query, after DDL operations have changed the schema of a table that the prepared object or the SPL routine references.

The IFX\_AUTO\_REPREPARE session environment option has this syntax:

IFX\_AUTO\_REPREPARE session environment option

**IFX\_AUTO\_REPREPARE**

**OFF '0' ON '1' '3' '5' '7'**

### Usage

The value that is specified by the SET ENVIRONMENT IFX\_AUTO\_REPREPARE statement can enable or disable automatic reparation:

**'1' or ON**

Enables automatic reparation

**'0' or OFF**

Disables automatic reparation

**'3'**

Enables automatic reparation in optimistic mode

**'5'**

Enables automatic reparation on update statistics

**'7'**

Enables automatic reparation in optimistic mode and on update statistics

Numeric values require single- or double-quotation delimiters. Alphabetic values are not case-sensitive.

Optimistic mode offers faster performance by not checking statements that successfully ran less than a second ago. In the unlikely event that tables were modified in the interim, some -710 errors might occur.

The database server might not detect some changes to a table schema that invalidate prepared objects or SPL routines, even when `IFX_AUTO_REPREPARE` is enabled. For example, changes to a table schema by one session causes concurrent sessions to receive error -710 when they attempt to read the same table after they obtain a shared lock.

Enabling `IFX_AUTO_REPREPARE` might have no effect on prepared statements and SPL routines that reference tables in which DDL operations change the number of columns in the table, or change the data type of a column. To avoid error -710 after these schema changes, you typically must reissue the `DESCRIBE` statement, the `PREPARE` statement, and (for cursors associated with routines) the `UPDATE STATISTICS FOR ROUTINE` statement for any routines that reference the table whose schema has been modified.

If enabling the `IFX_AUTO_REPREPARE` session environment variable results in a runtime error, that error is passed back to the application.

## Examples

The following statement enables automatic reparation after DDL operations on tables that prepared objects or SPL routines reference:

```
SET ENVIRONMENT IFX_AUTO_REPREPARE '1';
```

That setting overrides the setting of the `AUTO_REPREPARE` configuration parameter, if it is zero or `'None'`, for the remainder of the current session, or until you reset `IFX_AUTO_REPREPARE`.

The following statement, which uses an equivalent keyword, has the same effect for the current session:

```
SET ENVIRONMENT IFX_AUTO_REPREPARE on;
```

The following sequence of statements from different sessions will result in a -710 error, even though `IFX_AUTO_REPREPARE` is enabled for Session 1:

1. Session 1 prepares the following statement: `PREPARE s FROM "SELECT c1, c2 FROM t1"`
2. Session 2 drops column `c2` from table `t1`: `ALTER TABLE t1 DROP (c2)`
3. Session 1 attempts to execute the following statement: `EXECUTE s INTO :v1, :v2`

As a result, the database server sends the -710 error to the client application because it cannot send a value for column `c2`, which no longer exists. For the statement to succeed, you must resubmit it without referencing column `c2`.

When you are satisfied with how your client application currently handles errors from schema changes, you can stop overriding the system-wide setting of the `AUTO_REPREPARE` configuration parameter. For example, you can use one of the following equivalent statements:

```
SET ENVIRONMENT IFX_AUTO_REPREPARE OFF;
SET ENVIRONMENT IFX_AUTO_REPREPARE off;
SET ENVIRONMENT IFX_AUTO_REPREPARE "0";
SET ENVIRONMENT IFX_AUTO_REPREPARE '0';
```

---

[SET ENCRYPTION PASSWORD statement on page 896](#)

## IFX\_BATCHEDREAD\_INDEX session environment option

You can use the `IFX_BATCHEDREAD_INDEX` session environment option of the `SET ENVIRONMENT` statement of SQL to enable the query execution plans that execute light scans on the indexes of large tables, bypassing the buffer pool by using session memory to read directly from disk.

`IFX_BATCHEDREAD_INDEX` session environment option

**SET ENVIRONMENT IFX\_BATCHEDREAD\_INDEX**

'1' '0'

### Usage

When the `IFX_BATCHEDREAD_INDEX` configuration parameter not set, or is set to `0`, enabling the `IFX_BATCHEDREAD_INDEX` session environment option can improve the performance of some DML operations on indexed tables.

To set this session environment variable, specify one of the following digits as a quoted string:

**'1' or "1"**

Enables the query optimizer to execute light scans for indexes during the session.

**'0' or "0"**

Prevents the query optimizer from executing light scans for indexes.

For example, to enable the optimizer use light scans for reading index keys, specify:

```
SET ENVIRONMENT IFX_BATCHEDREAD_INDEX '1';
```

The following statement disables the same query optimizer feature:

```
SET ENVIRONMENT IFX_BATCHEDREAD_INDEX '0';
```

In sessions where the `IFX_BATCHEDREAD_INDEX` configuration parameter and the `IFX_BATCHEDREAD_INDEX` session environment variable have different settings, the setting of the session environment variable takes precedence over the configuration parameter setting for the duration of the session, or until the `IFX_BATCHEDREAD_INDEX` session environment variable is reset.

The default value of the `IFX_BATCHEDREAD_INDEX` configuration parameter in the `onconfig.std` file is `1`. That value can be reset to zero, however, disabling light scans of indexes, by either of the following `onmode` commands:

```
EXECUTE FUNCTION task("onmode", "wf", "IFX_BATCHEDREAD_INDEX=0");
EXECUTE FUNCTION task("onmode", "wm", "IFX_BATCHEDREAD_INDEX=0");
```

When `IFX_BATCHEDREAD_INDEX` has been disabled by those function calls, running the `SET ENVIRONMENT` statement

```
SET ENVIRONMENT IFX_BATCHEDREAD_INDEX "1";
```

restores support for light scans on indexes during the current session, if you expect that light scans on indexes will be more efficient for some DML operations in your application.

For more information about the advantages of light scans in queries of large tables, and restrictions on light scans, see [IFX\\_BATCHEDREAD\\_TABLE session environment option on page 929](#)

## IFX\_BATCHEDREAD\_TABLE session environment option

Use the IFX\_BATCHEDREAD\_TABLE environment option of the SET ENVIRONMENT statement to enable or disable light scans on compressed tables, tables with rows that are larger than a page, and tables with VARCHAR, LVARCHAR, and NVARCHAR data during the current session.

A light scan bypasses the buffer pool by utilizing session memory to read directly from disk. Query execution plans that uses light scans on large tables can improve performance, compared to plans using full-table scans.

IFX\_BATCHEDREAD\_TABLE environment option

**SET ENVIRONMENT IFX\_BATCHEDREAD\_TABLE**

'1' | '0'

### Usage

When the **BATCHEDREAD\_TABLE** configuration parameter is not enabled, enabling the IFX\_BATCHEDREAD\_TABLE session environment variable can improve the performance of some DML operations on indexed tables.

To set this session environment variable, specify one of the following digits as a quoted string:

'1' or "1"

Enable light scans during the session for query execution on compressed tables, on tables with rows larger than a page, and on tables with VARCHAR, LVARCHAR, and NVARCHAR columns

'0' or "0"

Prevent the query optimizer from using these light scans for the session.

For example, the following statement enables queries to perform light scans on compressed tables, on tables with rows larger than a page, and on tables with character data types of variable length:

```
SET ENVIRONMENT IFX_BATCHEDREAD_TABLE '1';
```

The following statement restores the default restriction on light scans of tables with those attributes:

```
SET ENVIRONMENT IFX_BATCHEDREAD_TABLE "0";
```

### Light scans

Light scans can provide performance advantages over other query execution plans that use the buffer pool for sequential scans or for skip scans of large tables. The following requirements, however, restrict the contexts in which the query optimizer can consider execution paths that include a light scan:

- The optimizer must choose a sequential scan or a skip-scan of the table.
- The table must store at least a megabyte (MiB) of data.
- One of the following locking conditions must be satisfied:
  - The isolation level is not Cursor Stability, and you hold at least a shared lock on the entire table.
  - The isolation level is Dirty Read, or the database transaction logging mode is WITH NO LOG.

But even if all of the optimizer plan, table size, and locking requirements listed above are satisfied, the following additional table restrictions can prevent light scans on tables with any of the following attributes. The tables cannot be

- compressed tables,
- tables with rows that are larger than a page,
- tables of variable row length.

The variable row length restriction prohibits tables with VARCHAR, LVARCHAR, or NVARCHAR columns, or with ROW-type columns that include VARCHAR, LVARCHAR, or NVARCHAR fields, or with data types DISTINCT of these variable-length types.

Although these three table restrictions are in effect by default, they do not prevent light scans on qualifying large tables in databases where the **BATCHEDREAD\_TABLE** configuration parameter is enabled, or in sessions where the BATCHEDREAD\_TABLE session environment option is enabled.

In both examples, the double quotation-mark character ( " ) could be substituted as the delimiters, but as in any SET ENVIRONMENT operation, an undelimited digit for the setting returns an error:

```
SET ENVIRONMENT IFX_BATCHEDREAD_TABLE 0; --Fails to disable light scans
                                         --on qualifying large tables
```

In sessions where the **IFX\_BATCHEDREAD\_TABLE** configuration parameter and the IFX\_BATCHEDREAD\_TABLE session environment variable have different settings, the setting of the session environment variable takes precedence over the configuration parameter setting for the duration of the session, or until the IFX\_BATCHEDREAD\_TABLE session environment variable is reset.

**Important:**

The lists of table attributes identified above as preventing light scans are not exhaustive. Tables with any of the following attributes cannot be processed using light scans in query execution plans, regardless of the current setting of the **IFX\_BATCHEDREAD\_TABLE** configuration parameter or the IFX\_BATCHEDREAD\_TABLE session environment variable:

- tables with data stored in blobspaces,
- tables with data stored in smart blobspaces,
- tables of variable row length.

## IFX\_SESSION\_LIMIT\_LOCKS session environment option

When IFX\_SESSION\_LIMIT\_LOCKS is set in the session, its setting can specify a lower limit than the **SESSION\_LIMIT\_LOCKS** configuration parameter value for the maximum number of locks for users who are not administrators. This option, however, cannot restrict the number of locks in the session of a user who holds administrative privileges, such as user **informix** or a DBSA user, and cannot specify a limit for nomadministrative users below 500 locks.

The SET ENVIRONMENT IFX\_SESSION\_LIMIT\_LOCKS statement cannot reset the maximum number of locks in a session to a value higher than the current setting of the **SESSION\_LIMIT\_LOCKS** configuration parameter.

The SET ENVIRONMENT AUTOLOCATE statement of SQL supports the following syntax:

IFX\_SESSION\_LIMIT\_LOCKS environment option  
**SET ENVIRONMENT IFX\_SESSION\_LIMIT\_LOCKS**  
 'integer'

| Element        | Description   | Restrictions   | Syntax                                     |
|----------------|---|--|--|
| <i>integer</i> | Nonnegative integer that defines how many locks in the internal lock table are available during the session for nonadministrative users | Must be in the range <code>500 integer</code> <b>SESSION_LIMIT_LOCKS</b> value | <a href="#">Quoted String on page 1424</a> |

## Usage

For users who are not administrators of the database server instance, the IFX\_SESSION\_LIMIT\_LOCKS session environment option can have an integer values greater than `499` but no greater than the current value of the **SESSION\_LIMIT\_LOCKS** configuration parameter.

```
'integer' OR "integer"
```

This defines the maximum number of locks that a nonadministrative user can hold during the session. If the **SESSION\_LIMIT\_LOCKS** configuration parameter is not set, the upper limit is 2,147,483,647 locks.

If the IFX\_SESSION\_LIMIT\_LOCKS session environment option and the **SESSION\_LIMIT\_LOCKS** configuration parameter are set to different values, the session environment option takes precedence over the configuration parameter for operations during the current sessions by users who are not administrator, but only until the current session ends. If neither of those values is set, the default limit for every user is 2,147,483,647 locks.

### Lock limits set by users who are not administrators

If you are a regular user, you (or the sysdbopen routine that configures your session) can set the IFX\_SESSION\_LIMIT\_LOCKS session environment option only to an unsigned integer value between the minimum (`500`) and the current value set by the **SESSION\_LIMIT\_LOCKS** configuration parameter.

For example, you might execute the following statement to restrict subsequent DDL and DML operations during the session to no more than 1056 locks:

```
SET ENVIRONMENT IFX_SESSION_LIMIT_LOCKS '1056';
```

If you attempt to specify an invalid value, the database server returns an error:

```
SET ENVIRONMENT IFX_SESSION_LIMIT_LOCKS '400'; --Below lower limit
-26041: Invalid values specified for the environment variable.
```

Issuing this exception is unlike the behavior of the **SESSION\_LIMIT\_LOCKS** configuration parameter, which replaces any nonnegative setting in the range from `0` to `499`, or any negative value, with `500`, the minimum value for nonadministrative users.

**Important:**

Because an insufficient locks can cause DML or DDL operations to fail, nonadministrative users should generally use caution when considering whether to use this session environment variable to restrict the number of locks available in contexts like these:

- If the session is using Repeatable Read isolation level for operations on large tables, because each row touched requires a lock.
- If the session of a non-DBSA user is running commands of the **cdr** utility of Enterprise Replication.

In data processing contexts that require very large numbers of locks, however, administrators might set **SESSION\_LIMIT\_LOCKS** (or might set **IFX\_SESSION\_LIMIT\_LOCKS** in sysdbopen routines for specific users or for specific roles) to a value intended to reduce the risk of nonadministrative users in concurrent sessions depleting the lock resources of the database server, thereby interfering with massively lock-intensive operations.

### Lock limits set by administrative users

If you are a user who holds administrative privileges, such as user **informix** or a DBSA user, the setting of **IFX\_SESSION\_LIMIT\_LOCKS** has no effect. The only value that you can set is `2147483647`, which is already the default limit for administrative users. If you attempt to set this option to any other specific value, the database server will either issue the `-26041` invalid value error, or else error `-26000`, indicating that administrative users cannot set a limit on the locks in their own sessions:

```
SET ENVIRONMENT IFX_SESSION_LIMIT_LOCKS "2147456789";

-26000 Locks cannot be limited for a user who has administrative privileges.
```

In releases earlier than version 12.10.xC4, it was possible for administrators to restrict themselves, but this is no longer an option.

### Lock limits for sessions in tenant databases

An administrator can use the SQL administration API to create a tenant database with the **tenant create** argument to the `admin()` or `task()` function. The function call can include a **session\_limit\_locks**: parameter value to set a nondefault limit on the number of locks that nonadministrative users can hold in a session.

For example, this statement creates a tenant database called **companyC** with a **session\_limit\_locks**: limit of `250000` locks for each nonadministrative user session.

```
EXECUTE FUNCTION task('tenant create','companyC',
  '{dbspace:"companyC_dbs1,companyC_dbs2,companyC_dbs3",
  sbspace:"companyC_sbs",
  vpclass:"tvp_C,num=4",
  dbspacetemp:"companyC_tdb",
  session_limit_locks:"250000",
  logmode:"UNBUFFERED",
  locale:"en_us.8859-1"}'
);
```

Administrators can also use the **tenant update** argument to the `admin()` or `task()` function to reset the number of locks and other attributes of a tenant database. For example, the following function uses a **session\_limit\_locks**: value of `3000` to change that limit for the same **companyC** tenant database:

```
EXECUTE FUNCTION task('tenant update','companyC',
  '{session_limit_locks:"3000"}');
```

Multiple properties can be reset by a single **"tenant update"** function call, but this example resets only the **session\_limit\_locks** property of **companyC**. The changed limit takes effect for new sessions.

If the **companyC** database was assigned a session limit of **3000** by the previous SQL administration API **"tenant update"** example, the following statement fails:

```
SET ENVIRONMENT IFX_SESSION_LIMIT_LOCKS '5000';
```

The example fails because this session environment variable cannot be set above the limit defined in the current setting of the **session\_limit\_locks** property of the tenant database.

In tenant databases, a sysdbopen session configuration routine that includes the SET ENVIRONMENT IFX\_SESSION\_LIMIT\_LOCKS statement can set a limit on locks that is lower than the **session\_limit\_locks** setting of the tenant database:

```
SET ENVIRONMENT IFX_SESSION_LIMIT_LOCKS '1600';
```

If the **session\_limit\_locks** property currently specifies a limit of **3000**, that limit would be temporarily reduced to **1600**. This lower limit on locks persists in the tenant database for all new sessions of nonadministrative users, until the session in which sysdbopen routine set the new lower limit terminates. The limit on locks then reverts to the current **session\_limit\_locks** setting.

In tenant databases, as in all databases, the IFX\_SESSION\_LIMIT\_LOCKS setting has no effect on users who hold administrative privileges, such as user **informix** or DBSA users.

## IMPLICIT\_PDQ session environment option

Use the IMPLICIT\_PDQ session environment option to allow the database server to determine the amount of memory allocated to a query, ignoring the explicit system default **PDQPRIORITY** environment variable setting.

IMPLICIT\_PDQ environment option

**SET ENVIRONMENT IMPLICIT\_PDQ**

**OFF ON**

*'integer'*

| Element        | Description  | Restrictions                             | Syntax                                     |
|----------------|--|--|--|
| <i>integer</i> | Nonnegative integer limiting the memory available to a query in the session as this percentage of the <b>PDQPRIORITY</b> value | Must be in the range $0 < integer < 101$ | <a href="#">Quoted String on page 1424</a> |

### Usage

Only systems that support **PDQPRIORITY** can reset the IMPLICIT\_PDQ session environment variable, which can have the following values:

The `IMPLICIT_PDQ` environment option can be set to the following values:

**OFF**

Disable `IMPLICIT_PDQ`. The server calculates no implicit `PDQPRIORITY`.

**ON**

The server automatically calculates an implicit `PDQPRIORITY` to use for each query.

**'integer' or "integer"**

Use *integer*% of the server-calculated implicit `PDQPRIORITY` value for each query, where *integer* is a nonnegative whole number in the range 1-100.

Unless `BOUND_IMPL_PDQ` is also set, the database server ignores the explicit setting of the `PDQPRIORITY` environment variable when `IMPLICIT_PDQ` is set to `ON` or to `"100"`.

The database server does not allocate more memory, however, than is available when `PDQPRIORITY` is set to `"100"`. The maximum amount of memory that the database server can allocate is limited by the physical memory available to your system, and by the settings of these parameters:

- The `PDQPRIORITY` environment variable
- The most recent `SET PDQPRIORITY` statement of SQL
- The `MAX_PDQPRIORITY` configuration parameter
- The `DS_TOTAL_MEMORY` configuration parameter
- The `BOUND_IMPL_PDQ` session environment variable

When concurrent queries are running, the `DS_MAX_QUERIES` configuration parameter setting can also restrict the amount of `PDQ` memory available for a new query.

By default, `IMPLICIT_PDQ` is not enabled. When `IMPLICIT_PDQ` is set to `OFF`, whether explicitly or by default, the database server does not override the current `PDQPRIORITY` setting when allocating resources to queries. For example, the following statement prevents the server from using implicit `PDQPRIORITY` for subsequent queries in the session:

```
SET ENVIRONMENT IMPLICIT_PDQ OFF;
```

If you set `IMPLICIT_PDQ` to an integer value between 1 and 100, the database server scales its estimate by the specified percentage. If you set a low value, the amount of memory allocated to the query is reduced, which might increase the risk of query-operator overflow. The following statement restricts the memory available for subsequent queries in the session to 75% of the calculated implicit `PDQPRIORITY`:

```
SET ENVIRONMENT IMPLICIT_PDQ '75';
```

To request the database server to determine memory allocations for queries and distribute memory among query operators according to their needs, enter the following statement:

```
SET ENVIRONMENT IMPLICIT_PDQ ON;
```

To require the database server to use explicit `PDQPRIORITY` settings as the upper bound and optional lower bound of memory that it grants to a query, set the `BOUND_IMPL_PDQ` session environment option.

Star-join query execution plans require `PDQ` priority to be set. Setting the `IMPLICIT_PDQ` session environment option to enable implicit `PDQ` offers an alternative. If `IMPLICIT_PDQ` is set to `ON` for the session, then a star-join execution plan will be

considered without explicit setting PDQPRIORITY. The SET ENVIRONMENT IMPLICIT\_PDQ ON statement can be issued by a **sysdbopen** routine, so that users automatically enable implicit PDQ when they open the database. In this case, the query optimizer automatically considered a star join without explicit PDQPRIORITY setting by the user.

The IMPLICIT\_PDQ functionality for a query requires at least LOW level distribution statistics on all tables in the query. If distribution statistics are missing for one or more tables in the query, the IMPLICIT\_PDQ setting has no effect. This restriction also applies to star join queries, which are not supported in the case of missing statistics.

For information on creating a **sysdbopen** routine and on specifying the users whose sessions it will affect, see the topic Using SYSDBOPEN and SYSDBCLOSE Procedures. For information about the **PDQPRIORITY** environment variable, see the *Informix® Guide to SQL: Reference*. For information about the **DS\_TOTAL\_MEMORY** and **MAX\_PDQPRIORITY** configuration parameters, see the .

## INFORMIXCONRETRY session environment option

Use the INFORMIXCONRETRY session environment option of the SET ENVIRONMENT statement to specify the maximum number of additional connection attempts that can be made to each database server during a single CONNECT statement in the current session, after the initial connection attempt fails. All these attempts must be made within the time limit that the **INFORMIXCONTIME** setting specifies.

The INFORMIXCONRETRY session environment option has this syntax:

INFORMIXCONRETRY environment option

**SET ENVIRONMENT INFORMIXCONRETRY**

**'1'** *integer*

| Element        | Description   | Restrictions  | Syntax  |
|----------------|---|---|---|
| <i>integer</i> | The maximum number of retry attempts during a CONNECT statement | Must be greater than zero. If you specify no value, the default behavior is a single retry. | <a href="#">Literal Number on page 1419</a> as <a href="#">Quoted String on page 1424</a> |

### Usage

Use the INFORMIXCONRETRY session environment option to specify the maximum number of additional connection attempts that each CONNECT statement can make for a server-to-server connection during the session, if the first attempt of fails to establish a connection to the target database server instance. You can specify a nonzero *integer* value for this limit on the maximum number of retries by the CONNECT statement:

***integer* > 0**

If the first attempt by the CONNECT statement to establish a connection to a database server fails, this value sets an upper limit on the number of additional attempts.

If no connection with another database has been established after (*integer* + 1) attempts, or after the time limit that INFORMIXCONTIME specifies has been exceeded, the CONNECT statement returns an error.

For the current session only, the setting of the `INFORMIXCONRETRY` session environment option overrides any other value that is currently set for the `INFORMIXCONRETRY` client environment variable or for the `INFORMIXCONRETRY` configuration parameter.

### Order of precedence for `INFORMIXCONRETRY` settings

This is the descending order of precedence (highest to lowest) among methods for setting the maximum number of retry attempts for `CONNECT` statements:

- The `SET ENVIRONMENT INFORMIXCONRETRY` statement (for a session)
- The `INFORMIXCONRETRY` client environment variable setting.
- If `INFORMIXCONRETRY` configuration parameter in the `onconfig` file.
- The system default value of 1 additional attempt to establish a new connection to a server.

Unless the setting of the `INFORMIXCONRETRY` session environment option, or of the `INFORMIXCONRETRY` configuration parameter, or of the `INFORMIXCONRETRY` environment variable is an integer greater than zero, the default behavior of the `CONNECT` statement after a failed initial connection attempt is to attempt a single connection retry.

### Examples of setting `INFORMIXCONRETRY`

For example, the following statement resets the `INFORMIXCONRETRY` session environment option to the default value of 1, restricting the database server to no more than a single additional connection attempt if the first attempt fails:

```
SET ENVIRONMENT INFORMIXCONRETRY;
```

The next example specifies that, if the initial connection attempt fails, up to three additional connection attempts are made before the database server issues an error.

```
SET ENVIRONMENT INFORMIXCONRETRY '3';
```

You can also use double ( `"` ) quotation marks to delimit the setting, which allows five retries (or up to a total of 6 connection attempts) in the following example:

```
SET ENVIRONMENT INFORMIXCONRETRY "5";
```

#### Important:

If the `INFORMIXCONTIME` session environment option or the `INFORMIXCONTIME` configuration parameter is set to a time interval, that value takes precedence over the `INFORMIXCONRETRY` setting. That is, the connection attempts can end after the limit in seconds from the `INFORMIXCONTIME` setting has elapsed, even if this limit is exceeded before the `INFORMIXCONRETRY` limit on attempts is reached.

## `INFORMIXCONTIME` session environment option

Use the `INFORMIXCONTIME` session environment option of the `SET ENVIRONMENT` statement to set an upper limit on the number of seconds while the current session attempts to establish a connection to another database server, before an error is returned.

The INFORMIXCONTIME session environment option has this syntax:

INFORMIXCONTIME environment option

**SET ENVIRONMENT INFORMIXCONTIME**

**'1' 'integer'**

| Element        | Description  | Restrictions  | Syntax  |
|----------------|--|---|---|
| <i>integer</i> | An unsigned integer value<br>> 0 sets the maximum number of seconds to attempts to establish a connection to a database server | Must be delimited between single (') or double (") quotation marks. A setting of '0' defaults to the setting of the <b>INFORMIXCONTIME</b> configuration parameter. | <a href="#">Literal Number on page 1419</a> as <a href="#">Quoted String on page 1424</a> |

### Usage

Use the INFORMIXCONTIME session environment option of the SET ENVIRONMENT statement to limit the number of *seconds* to spend attempting to establish a connection to a database server in the current session, before the connection effort times out with an error.

**'integer' > 0**

This value sets an upper limit on the time spent attempting to establish a connection, including (if the initial attempt fails) at least one additional attempt.

After the time limit that INFORMIXCONTIME specifies has been exceeded, or if no connection with another database server has been established after (*integer\_R* + 1) attempts, for *integer\_R* the INFORMIXCONRETRY setting, the CONNECT statement or the implicit connection fails, and the database server returns an error. By setting the INFORMIXCONTIME and INFORMIXCONRETRY session environment variables to configure your sever-to-server connection capability in the current session, you can minimize connection errors. To estimate the optimal value for INFORMIXCONTIME, take into account the total distance between nodes, the hardware speed, the volume of traffic, and the concurrency level of the network.

### Order of precedence for time limits on connections

This is the ascending order of precedence (lowest to highest) among the methods for setting an upper limit on the amount of time that a CONNECT statement can spend attempting to connect to a database server instance:

- System default value of 60 seconds, if none of the methods below are set.
- **INFORMIXCONTIME** configuration parameter
- **INFORMIXCONTIME** client environment variable
- SET ENVIRONMENT INFORMIXCONTIME statement of SQL.

The INFORMIXCONTIME session environment option can override the setting of the client **INFORMIXCONTIME** environment variable, or of the **INFORMIXCONTIME** configuration parameter, or of the system default value, if any of these has established a time limit different from the SET ENVIRONMENT INFORMIXCONTIME value.

## Setting session environment options for connections

The value of the `INFORMIXCONTIME` session environment option is divided by the value of the `INFORMIXCONRETRY` session environment option to determine the maximum number of seconds between successive connection attempts, if the previous attempt of the same `CONNECT` statement failed to establish a connection.

For example, the following statements set `INFORMIXCONTIME` to 60 seconds and `INFORMIXCONRETRY` to one retry:

```
SET ENVIRONMENT INFORMIXCONTIME '60';
SET ENVIRONMENT INFORMIXCONRETRY '1';
```

In this example, the `CONNECT` statement attempts to establish a connection for 60 seconds. An initial attempt is made to connect to the database server at 0 seconds. If the `INFORMIXCONTIME` session environment option is set to the default value of '0', an additional attempt to connect is made within 60 seconds, if necessary, before connection failure error -908 is returned.

Similarly, you can configure these session environment options for multiple retries. With the same `INFORMIXCONTIME` setting, the following statement specifies three additional retries:

```
SET ENVIRONMENT INFORMIXCONRETRY '3';
```

If `INFORMIXCONRETRY` is set to '3', up to three additional attempts to connect to the database server are made (at 20, 40, and 60 seconds, if necessary), before an error is returned.

This 20-second interval is the result of dividing the `INFORMIXCONTIME` value by the `INFORMIXCONRETRY` value.

If you set the `INFORMIXCONTIME` session environment option to '0', as in this example,

```
SET ENVIRONMENT INFORMIXCONTIME '0';
```

the database server automatically uses the setting of the `INFORMIXCONTIME` configuration parameter. If the `INFORMIXCONTIME` parameter is not set, its default value of 60 seconds is used during subsequent `CONNECT` statements in the session.

## Implicit connections with database statements

If the `CONNECT` statement does not begin your application, its first SQL statement must either be one of the following *database statements*, or else be a single-statement prepared object for one of the same statements:

- DATABASE
- CREATE DATABASE
- DROP DATABASE

If one of these statements, rather than the `CONNECT` statement, is the first SQL statement in an application, that database statement can establish a connection to a database server that is known as an *implicit* connection, because no `CONNECT` statement in the session has established an explicit connection. To establish the implicit connection, a database statement must specify one of the following, either as an SQL identifier or as the content of a variable:

- a database server and a database,
- or a database server only,
- or a database only.

If the database statement specifies only a database, the database server obtains a database server name from the **DBPATH** environment variable setting. For more information on establishing implicit connections in UNIX or Windows environments, see the topic [Specifying the Database Environment on page 188](#).

If you issue the CONNECT statement after the application establishes an implicit connection with only a database name, the CONNECT statement must search **DBPATH** to identify the database server for that database. For this search, the INFORMIXCONRETRY session environment option specifies the number of additional connection attempts that can be made for each database server entry in **DBPATH**.

- All appropriate servers in the **DBPATH** setting are accessed at least once, even if the INFORMIXCONTIME value is exceeded. In this context, the CONNECT statement might take longer than the INFORMIXCONTIME time limit to return an error that indicates a connection failure, or indicating that the database was not found.
- The INFORMIXCONTIME value is divided among the number of database server entries that are specified in **DBPATH**. Thus, if **DBPATH** contains numerous servers, you can use the SET ENVIRONMENT INFORMIXCONTIME statement to increase the INFORMIXCONTIME value accordingly. For example, if **DBPATH** contains three entries, in order to spend at least 30 seconds attempting each connection, set INFORMIXCONTIME to '90'.

```
SET ENVIRONMENT INFORMIXCONTIME '90';
```

## NOVALIDATE session environment option

Use the NOVALIDATE environment option to specify whether a foreign-key or check constraint that the ALTER TABLE ADD CONSTRAINT statement creates, or that has its constraint mode reset by the SET CONSTRAINTS statement, are in NOVALIDATE mode by default. The NOVALIDATE setting has no effect, however, on ADD CONSTRAINT or SET CONSTRAINT operations that specify DISABLED mode.

NOVALIDATE environment option

**SET ENVIRONMENT NOVALIDATE**

'1' ON

'0' OFF

### Usage

Enabling this session environment variable can prevent referential-integrity checking of the foreign-key constraint or checking the condition of the check constraint during these subsequent SQL statements:

- ALTER TABLE ADD CONSTRAINT
- SET CONSTRAINTS ENABLED
- SET CONSTRAINTS FILTERING

Bypassing validation during these data definition language (DDL) operations can improve the performance of the database server in contexts where there is no reason to expect integrity or check condition violations, or where validation of constraints can be postponed until after the tables are relocated to another database.

To set the NOVALIDATE session environment variable, specify one of these values:

**'1' OR ON**

You do not need to explicitly include the `NOVALIDATE` keyword to bypass validation of the `ENABLED` or `FILTERING` constraint while either of those DDL statements is running.

**'0' OR OFF**

This restores the default behavior of those DDL statements, so that the database server automatically checks the table for constraint violations during the `ALTER TABLE` or `SET CONSTRAINTS` operation that created or enabled the constraint.

**Note:** Whether or not the `SET ENVIRONMENT NOVALIDATE` session environment option is enabled, any `NOVALIDATE` attribute that the `ALTER TABLE ADD CONSTRAINT` statement or the `SET CONSTRAINTS` option of the `SET Database Object Mode` statement applied to the object mode of a constraint is automatically dropped after execution of that DDL statement completes. The mode of the constraint becomes whatever the `SET CONSTRAINTS` or `ALTER TABLE` statement registered in the `sysobjstate` system catalog table, which ignores the `NOVALIDATE` attribute.

While you are creating `ENABLED` or `FILTERING` constraints with the `ALTER TABLE ADD CONSTRAINT` statement, or changing the mode of a constraint to `ENABLED` or `FILTERING` with the `SET CONSTRAINTS` statement, the `NOVALIDATE` option prevents the database server from checking for constraint violations while the `ALTER TABLE` or `SET CONSTRAINTS` statement is running. That can save significant time in moving large tables.

For example, the following statement enables the `NOVALIDATE` session environment variable:

```
SET ENVIRONMENT NOVALIDATE '1';
```

It has these subsequent effects during the following DDL operations on foreign-key or check constraints in the database to which the current session is connected:

- `SET CONSTRAINTS` options of the `SET Database Object Mode` statements for constraints change the default or explicit constraint mode to include `NOVALIDATE`, unless `DISABLED` is specified as the constraint mode.
- Constraints that the `ALTER TABLE ADD CONSTRAINT` statement specifies with no explicit mode are created in `ENABLED NOVALIDATE` mode by default.
- Constraints that the `ALTER TABLE ADD CONSTRAINT` statement specifies in `ENABLED` or in `FILTERING` mode are also in `NOVALIDATE` mode by default.

The following example restores the default constraint mode behavior:

```
SET ENVIRONMENT NOVALIDATE OFF;
```

For subsequent `SET CONSTRAINTS` or `ALTER TABLE ADD CONSTRAINT` statements that omit the `NOVALIDATE` keyword from the object mode of a constraint, the database server validates the referential integrity or check conditions of the table by performing a full-table scan or an index scan. For tables with a million rows, for example, the cost of this validation is substantial.

Suspending constraint-checking during `SET CONSTRAINTS` or `ALTER TABLE ADD CONSTRAINT` statements by enabling the `NOVALIDATE` session environment option can be efficient for tables that have been populated by OLTP operations that enforced the same constraints. After moving those tables to another database or to a data warehouse with their constraints

dropped or disabled, you can use the SET ENVIRONMENT NOVALIDATE ON statement to avoid the overhead of checking for violations while the constraints are being restored.

## Examples of setting NOVALIDATE

Like all SQL keywords, the ON and OFF settings are case insensitive.

Double ( " ) and single ( ' ) quotation marks are both valid as delimiters for the "1" and "0" settings, but both delimiters of a numeric setting must be the same.

For example, to make NOVALIDATE a default keyword in subsequent DDL operations setting the mode of constraints within the scope of this session environment option, use any of the following statements:

```
SET ENVIRONMENT NOVALIDATE '1';
SET ENVIRONMENT NOVALIDATE ON;
SET ENVIRONMENT NOVALIDATE "1";
SET ENVIRONMENT NOVALIDATE on;
```

Similarly, each of the following statements restores the default behavior that requires the explicit NOVALIDATE keyword in SQL operations that create or reset the mode of a constraint without checking:

```
SET ENVIRONMENT NOVALIDATE '0';
SET ENVIRONMENT NOVALIDATE OFF;
SET ENVIRONMENT NOVALIDATE "0";
SET ENVIRONMENT NOVALIDATE off;
```

## OPTCOMPIND session environment option

Use the OPTCOMPIND session environment option of the SET ENVIRONMENT statement to specify methods for the query optimizer to choose in join queries and MERGE statements of the currently executing routine.

The SET ENVIRONMENT OPTCOMPIND statement of SQL supports the following syntax:

```
OPTCOMPIND environment option
SET ENVIRONMENT OPTCOMPIND
'0' '1' '2' DEFAULT
```

### Usage

The OPTCOMPIND environment option can improve the performance of databases that are used for both decision support and online transaction processing. Use this option to specify join methods for the query optimizer to use in queries of the same routine.

'0' or "0"

The query optimizer uses a nested-loop join where possible, rather than a sort-merge join or a hash join

'1' or "1"

If the transaction isolation level is Repeatable Read, the optimizer behaves as in setting '0', as described above; for any other isolation level, it behaves like setting '2', as described next.

'2' OR "2"

The query optimizer does not necessarily prefer nested-loop joins, but bases its decision entirely on the estimated cost, regardless of the transaction isolation mode.

#### DEFAULT

This keyword restores the system default value, as described in the **OPTCOMPIND** topic of the *Informix® Guide to SQL: Reference*

Any numeric setting of the SET ENVIRONMENT OPTCOMPIND statement can override the default setting of the **OPTCOMPIND** environment variable while the routine that issues this statement is running in the current session.

That is, the scope of this session environment setting is local to the routine that issues the SET ENVIRONMENT OPTCOMPIND statement. That setting persists only until the routine exits, or until the same routine issues another SET ENVIRONMENT OPTCOMPIND statement, rather than persisting for the entire session. After that routine terminates, the setting reverts to the system default value that the **OPTCOMPIND** environment variable specifies, or else the value set by another method in the order of precedence described below in this topic.

#### Important:

No other option to SET ENVIRONMENT has a scope that is local to the routine that sets the value. The settings of all the other SET ENVIRONMENT options persist until the session ends, or until another SQL statement in the same session resets their value.

### The system default value of OPTCOMPIND

This is the descending order of precedence for the default OPTCOMPIND value, from highest to lowest, if conflicting values have been set by different methods:

- the **OPTCOMPIND** environment variable setting
- OPTCOMPIND configuration parameter setting, if **OPTCOMPIND** is not set
- 2, if neither of the above are set.

### Examples of resetting OPTCOMPIND

The following statement replaces the default setting with a purely cost-based optimizer strategy:

```
SET ENVIRONMENT OPTCOMPIND '2';
```

The following statement has the same effect as the previous example, unless transaction isolation level is Repeatable Read:

```
SET ENVIRONMENT OPTCOMPIND '1';
```

If isolation level is Repeatable Read, the query optimizer chooses index scans. This is the recommended setting for Repeatable Read, because it reduces the risk of lock contention among connections when hash-join execution paths set temporary locks on all records of joined tables.

The next example makes the query optimizer prefer nested-loop joins over other possible join methods:

```
SET ENVIRONMENT OPTCOMPIND "0";
```

If a routine has set the OPTCOMPIND session environment option to a numeric value appropriate for the next join query, after that transaction completes, the same routine can issue the following statement to restore the system default value:

```
SET ENVIRONMENT OPTCOMPIND DEFAULT;
```

For more information about the different join methods that the optimizer can choose, and the performance implications of the OPTCOMPIND session environment setting, see your *Informix® Performance Guide*.

For more information about the OPTCOMPIND configuration parameter, see your .

For more information about the **OPTCOMPIND** environment variable, see your *Informix® Guide to SQL: Reference*.

## QUERY\_TIMEOUT session environment option

Use the QUERY\_TIMEOUT environment option of the SET ENVIRONMENT statement to limit the amount of clock time a query may take before being interrupted internally.

Units of the QUERY\_TIMEOUT value are seconds. This setting will not affect DML or DDL statements, or administration operations.

If a query times out, the client will receive SQL error 213 (Statement timed out or interrupted by user) and ISAM error 157 (Interrupted ISAM call).

The SET ENVIRONMENT QUERY\_TIMEOUT statement of SQL supports the following syntax:

### Syntax

**SET ENVIRONMENT QUERY\_TIMEOUT**

**0**

**- integer**

| Element        | Description   | Restrictions                                     | Syntax                                |
|----------------|---|--|---------------------------------------|
| <i>integer</i> | Non-negative integer that defines the maximum clock time a query is allowed | Must be in the range $1 \leq integer \leq 10000$ | <a href="#">Quoted String on page</a> |

### Usage

The QUERY\_TIMEOUT session environment option can have the following values:

- '0' or "0"  
Disables the timeout for the current session.
- '*integer*' or "*integer*" where  $1 \leq integer \leq 10000$

Enables the query timeout for the current session and triggers an interrupt of any query that runs longer than *integer* seconds. Note that the query run time is evaluated based on clock time, not the cumulative time the session's threads spend running on a VP.

It is not possible to set an instance-wide query timeout for all sessions. Each individual session must configure its own timeout.

## RETAINUPDATELOCKS session environment option

The RETAINUPDATELOCKS environment option can improve concurrency in Dynamic SQL applications that include the SELECT ... FOR UPDATE statement. This option can modify the behavior of the current transaction isolation level at runtime if the session is using the Committed Read, Dirty Read, or Cursor Stability isolation levels to enable (or to disable) the `RETAIN UPDATE LOCKS` clause of the SET ISOLATION statement.

The RETAINUPDATELOCKS session environment option supports the following syntax:

RETAINUPDATELOCKS session environment option

```
SET ENVIRONMENT RETAINUPDATELOCKS '
COMMITTED READ CURSOR STABILITY DIRTY READ ALL NONE
'
```

### Usage

The RETAINUPDATELOCKS option accepts any one of five settings that can affect the current Informix® isolation level, as well as the isolation levels established by SET ISOLATION statements issued after the SET ENVIRONMENT statement. For every setting except `'NONE'`, the effect of the setting is to implicitly include the RETAIN UPDATE LOCKS keywords in SET ISOLATION specifications:

#### **'COMMITTED READ'**

The database server retains any update lock until the end of a transaction that uses the Committed Read isolation level.

#### **'CURSOR STABILITY'**

The database server retains any update lock until the end of a transaction that uses the Cursor Stability isolation level.

#### **'DIRTY READ'**

The database server retains any update lock until the end of a transaction that uses the Dirty Read isolation level.

#### **'ALL'**

The database server retains any update lock until the end of the transaction that uses the Committed Read, Dirty Read, or Cursor Stability isolation level.

**'NONE'**

the RETAINUPDATELOCKS feature is disabled until the session ends, or until another SET ISOLATION or SET ENVIRONMENT statement re-enables the retention of update locks. Under the `NONE` setting, if your application defines an update cursor, the database server releases its update locks at the next FETCH operation, or when the update cursor is closed. Update locks are not retained, even if the Committed Read, Dirty Read, or Cursor Stability isolation level had enforced RETAIN UPDATE LOCKS behavior before the SET ENVIRONMENT RETAINUPDATELOCKS 'NONE' statement executed.

When the RETAINUPDATELOCKS environment option is enabled for the current isolation level, the database server, by default, retains the update lock on a row until the end of the transaction. Any update locks are held until the transaction is committed or rolled back, whether or not the SET ISOLATION statement that defined the isolation level included the RETAIN UPDATE LOCKS keywords. When this option is set to ALL or to the name of the current Informix® isolation level (if this level is Committed Read, Dirty Read, or Cursor Stability), this setting prevents concurrent users in other sessions from deleting or updating a row on which you have placed an update lock, but that you have not yet updated.

By specifying NONE as the RETAINUPDATELOCKS setting, you disable this feature and restore the default locking behavior. When NONE is the setting, unless the isolation level has been set by a SET ISOLATION statement that explicitly included the RETAIN UPDATE LOCKS keywords, the database server releases the update lock at the next FETCH operation, or when the cursor is closed.

The SET ENVIRONMENT RETAINUPDATELOCKS statement has no effect on update cursors if the Informix® isolation level is REPEATABLE READ. Similarly out of scope are transactions whose isolation level has been set by the SET TRANSACTION statement, which defines ANSI/ISO-compliant isolation levels, rather than Informix® isolation levels. (For more information about Informix® and ISO isolation levels, see the topic [Comparing SET TRANSACTION with SET ISOLATION on page 1003](#).)

Like other SET ENVIRONMENT options, these settings are not case-sensitive, but they require single ( ' ) or double ( " ) quotation marks as delimiters. For example, the settings `'ALL'` and `'all'` and `"aLl"` and `"aLl"` have the same effect.

**Examples of setting RETAINUPDATELOCKS**

The SET ENVIRONMENT RETAINUPDATELOCKS statement takes effect (by resetting the session environment) when it is issued. It can be issued outside a transaction. If the isolation level of the current transaction matches the setting specified after the RETAINUPDATELOCKS keyword, the new setting can change the RETAIN UPDATE LOCKS behavior of the transaction that is running when the statement is issued.

For example, consider the following SET ENVIRONMENT and SET ISOLATION statements:

```
BEGIN WORK; --Begin first transaction
SET ENVIRONMENT RETAINUPDATELOCKS 'COMMITTED READ';
SET ISOLATION TO COMMITTED READ LAST COMMITTED;
SELECT ... FOR UPDATE ...
...
COMMIT WORK;
SET ENVIRONMENT RETAINUPDATELOCKS 'DIRTY READ';
BEGIN WORK; --Begin second transaction
SET ISOLATION TO COMMITTED READ LAST COMMITTED;
SELECT ... FOR UPDATE ...
...
COMMIT WORK;
```

In the first transaction above, the `RETAINUPDATELOCKS` setting in the `SET ENVIRONMENT` statement makes the retention of update locks the default behavior for the Committed Read isolation level. As a result, the database server interprets the first `SET ISOLATION` statement, which specifies Committed Read but has no `RETAIN UPDATE LOCKS` clause, as if it had included that clause:

```
SET ISOLATION TO
  READ LAST COMMITTED RETAIN UPDATE LOCKS;
```

Because the `SET ENVIRONMENT RETAINUPDATELOCKS` statement in the second transaction specifies `DIRTY READ` as its setting, however, it has no effect on the second `SET ISOLATION` statement, which defines a Committed Read isolation level. Each of the settings that correspond to a specific Informix® isolation level only affect update locks in transactions that use the same isolation level.

If your goal is to enable retention of update locks in the Dirty Read isolation level, this is a more appropriate example than the second transaction above:

```
SET ENVIRONMENT RETAINUPDATELOCKS 'DIRTY READ';
BEGIN WORK; --Begin third transaction
SET ISOLATION TO DIRTY READ;
SELECT ... FOR UPDATE ...
...
COMMIT WORK;
```

In the third transaction, the database server interprets the `SET ISOLATION TO DIRTY READ` statement, which matches the `SET ENVIRONMENT` isolation level of Dirty Read, but has no `RETAIN UPDATE LOCKS` clause, as if it had included that clause:

```
SET ISOLATION TO DIRTY READ RETAIN UPDATE LOCKS;
```

In cross-server `SELECT ... FOR UPDATE` distributed queries, but some participating servers do not support update lock retention, the entire transaction conforms to the isolation level of the session that issued the transaction. If that session has an enabled `RETAINUPDATELOCKS` option in effect, it is also in effect for the servers that support update lock retention, but other participating servers follow their default behavior for releasing update locks.

The `SET ENVIRONMENT RETAINUPDATELOCKS` statement fails with error -26199 if the database in which it is issued does not support transaction logging.

### Setting `RETAINUPDATELOCKS` in the `sysdbopen()` procedure

For a user, for a role, or for the `PUBLIC` group, the built-in `sysdbopen()` routine can issue the `SET ENVIRONMENT RETAINUPDATELOCKS` statement when the session connects to a database in which `sysdbopen()` is defined, as in the following example.

```
CREATE PROCEDURE PUBLIC.SYSDBOPEN()
  SET PDQPRIORITY 10;
  SET ENVIRONMENT RETAINUPDATELOCKS 'ALL';
END PROCEDURE
```

After the example above takes effect, it prevents other sessions from modifying rows on which you have placed an update lock, so that you can update the rows later in the current transaction. Unless you issue another SQL statement within the same session to disable the retention of update locks, the effects of a `SET ENVIRONMENT RETAINUPDATELOCKS` statement that `sysdbopen()` issues persists until the end of the session.

This session-long persistence of the RETAINUPDATELOCKS value that **sysdbopen()** specifies, however, is a special case. Any other SPL routine can use the SET ENVIRONMENT statements to specify update lock retention for the Committed Read, Dirty Read, or Cursor Stability transaction isolation level, or for 'ALL', but their effect persists only while the routine is executing, and not after the routine exits.

### Restoring the default update lock behavior

In releases of Informix® earlier than version 11.50.xC6, the most recently executed SET ISOLATION statement specified the default for subsequent transactions. If the most recent SET ISOLATION statement included the RETAIN UPDATE LOCKS clause, it was necessary to execute the SET ISOLATION statement for the same isolation level (but without the RETAIN UPDATE LOCKS clause) to disable the retention of update locks.

In this release, however, if SET ENVIRONMENT RETAINUPDATELOCKS has enabled retention, you must explicitly run the `SET ENVIRONMENT RETAINUPDATELOCKS 'NONE'` statement to restore non-retention as the default behavior, as in the following example.

```
BEGIN WORK; --Begin first transaction
SET ISOLATION TO COMMITTED READ LAST COMMITTED;
SET ENVIRONMENT RETAINUPDATELOCKS 'COMMITTED READ';
SELECT ... FOR UPDATE ...
...
COMMIT WORK;
BEGIN WORK; --Begin second transaction
SET ENVIRONMENT RETAINUPDATELOCKS 'NONE';
SET ISOLATION TO COMMITTED READ LAST COMMITTED;
SELECT ... FOR UPDATE ...
...
```

In the first transaction above, the first SET ENVIRONMENT statement modifies the behavior of the Committed Read isolation level of the current transaction to retain update locks, even though the SET ISOLATION statement that established that isolation level preceded the SET ENVIRONMENT statement in the lexical order of statements within the transaction. The LAST COMMITTED specification for this isolation level is not affected by this SET ENVIRONMENT statement.

The SET ISOLATION statement in the second transaction is interpreted literally, however, because the default behavior was reset to NONE by the second SET ENVIRONMENT statement.

### Update lock retention in High Availability Clusters

In a high availability cluster environment, the RETAINUPDATELOCKS option is valid only on a primary server. Applications that require the retention of update locks must be run on the primary server if they include the SET ENVIRONMENT RETAINUPDATELOCKS statement. When it is issued from a secondary server, the statement has no effect on locking behavior, and the server returns an error.

### SELECT\_GRID session environment option

Use the SELECT\_GRID option of the SET ENVIRONMENT statement to define a default GRID clause for grid queries. This clause specifies a default grid or region from which to return a result set equivalent to logical UNION of qualifying rows from participating grid servers.

SELECT\_GRID environment option

### SET ENVIRONMENT SELECT\_GRID

'grid' 'region' DEFAULT

| Element       | Description  | Restrictions                 | Syntax                                  |
|---------------|--|------------------------------|---|
| <i>grid</i>   | Name of a default grid for queries with no GRID clause   | The <i>grid</i> must exist   | <a href="#">Identifier on page 1456</a> |
| <i>region</i> | Name of a default region for queries with no GRID clause | The <i>region</i> must exist | <a href="#">Identifier on page 1456</a> |

### Usage

The SELECT\_GRID session environment option can be set to any of three values:

#### 'grid'

This specifies the default grid from which SELECT statements that include no GRID clause can return a result set that is the logical UNION of distinct qualifying rows from all of the participating grid servers in the specified *grid*. While the SELECT\_GRID option of the SET ENVIRONMENT statement is set to the name of a grid, the database server that issued the SET ENVIRONMENT SELECT\_GRID '*grid*' statement interprets all queries as UNION grid queries.

#### 'region'

This specifies the default region from which SELECT statements that include no GRID clause can return a result set that is the logical UNION of distinct qualifying values from all of the participating grid servers in the specified region. While the SELECT\_GRID option of the SET ENVIRONMENT statement is set to the name of a region, the database server that issued the SET ENVIRONMENT SELECT\_GRID '*region*' statement interprets all queries as UNION grid queries.

#### DEFAULT

This setting specifies the default behavior that requires an explicit GRID clause. While the SELECT\_GRID option of the SET ENVIRONMENT statement is set to DEFAULT, the database server does not process every query that has no GRID clause as a grid query. That is, the DEFAULT setting specifies that there is no default GRID clause for SELECT statements. Use this option to disable the effects of a previous SET ENVIRONMENT SELECT\_GRID or SET ENVIRONMENT SELECT\_GRID\_ALL statement in the same session that defined a default GRID clause for all queries that include no GRID clause.

Unlike the SELECT\_GRID\_ALL option, the SELECT\_GRID setting enables subsequent queries that include no GRID clause to behave as grid queries that return distinct values.

The SELECT\_GRID and the SELECT\_GRID\_ALL options of the SET ENVIRONMENT statement are mutually exclusive. After you issue the SET ENVIRONMENT SELECT\_GRID or SET ENVIRONMENT SELECT\_GRID\_ALL statement, issuing a different option of either statement in the same session replaces whatever the previous SET ENVIRONMENT SELECT\_GRID or SET ENVIRONMENT SELECT\_GRID\_ALL statement established as the server behavior for grid queries in the session.

## Restrictions on SELECT\_GRID

Do not call the `ifx_gridquery_skipped_nodes()` function while the `SELECT_GRID` session environment variable is set to `'grid'` or to `'region'`.

The `SELECT_GRID` session environment option should not be set to `'grid'` or to `'region'` outside a grid context.

## Examples of setting SELECT\_GRID

The following statement establishes a default grid called **inverness** for the current session, and instructs the database server to interpret all queries that include no GRID clause as UNION grid queries for that grid:

```
SET ENVIRONMENT SELECT_GRID "inverness";
```

If **cawdor** were the name of a region in the **inverness** grid, the next example would instruct the database server to interpret all queries that include no GRID clause as UNION grid queries for the **cawdor** region, rather than having the entire **inverness** grid as their scope:

```
SET ENVIRONMENT SELECT_GRID "cawdor";
```

The following example overrides the effect of any previous `SET ENVIRONMENT SELECT_GRID` statement that established a default grid or a default region, and an implicit UNION operator, as the scope of subsequent queries that include no GRID clause:

```
SET ENVIRONMENT SELECT_GRID DEFAULT;
```

The statement above restores the default behavior for processing queries in the session, so that the database interprets only SELECT statements that explicitly include the GRID clause as grid queries.

For more information about grid queries, see the [GRID clause on page 809](#) and the .

---

[GRID clause on page 809](#)

## SELECT\_GRID\_ALL session environment option

Use the `SELECT_GRID_ALL` option of the `SET ENVIRONMENT` statement to define a default GRID clause for subsequent grid queries in the session. This clause specifies a default grid or region from which to return a result set equivalent to a logical UNION ALL of qualifying rows from participating grid servers.

`SELECT_GRID_ALL` environment option

**SET ENVIRONMENT SELECT\_GRID\_ALL**

`'grid' 'region' DEFAULT`

| Element           | Description  | Restrictions                     | Syntax                                  |
|-------------------|--|----------------------------------|---|
| <code>grid</code> | Name of a default grid for queries with no GRID clause | The <code>grid</code> must exist | <a href="#">Identifier on page 1456</a> |

| Element       | Description  | Restrictions                 | Syntax                                  |
|---------------|--|------------------------------|---|
| <i>region</i> | Name of a default region for queries with no GRID clause | The <i>region</i> must exist | <a href="#">Identifier on page 1456</a> |

## Usage

The SELECT\_GRID\_ALL session environment option can be set to any of three values:

### 'grid'

This specifies the default grid from which SELECT statements that include no GRID clause can return a result set that is the logical UNION ALL of qualifying rows, including duplicates, from all of the participating grid servers in the specified *grid*. While the SELECT\_GRID option of the SET ENVIRONMENT statement is set to the name of a grid, the database server that issued the SET ENVIRONMENT SELECT\_GRID\_ALL '*grid*' statement interprets all queries as UNION ALL grid queries.

### 'region'

This specifies the default region from which SELECT statements that include no GRID clause can return a result set that is the logical UNION ALL of qualifying values, including duplicates, from all of the participating grid servers in the specified region. While the SELECT\_GRID option of the SET ENVIRONMENT statement is set to the name of a region, the database server that issued the SET ENVIRONMENT SELECT\_GRID\_ALL '*region*' statement interprets all queries as UNION ALL grid queries.

## DEFAULT

This setting specifies the default behavior. While the SELECT\_GRID\_ALL option of the SET ENVIRONMENT statement is set to `DEFAULT`, the database server does not process every query that has no GRID clause as a grid query. Thus, the `DEFAULT` setting specifies that there is no default GRID clause for SELECT statements. Use this option to disable the effects of a previous SET ENVIRONMENT SELECT\_GRID or SET ENVIRONMENT SELECT\_GRID\_ALL statement that defined a default GRID clause for all queries that include no GRID clause.

Unlike the SELECT\_GRID option, the SELECT\_GRID\_ALL setting enables subsequent queries that include no GRID clause to behave as grid queries that return duplicate values.

The SELECT\_GRID\_ALL and the SELECT\_GRID options of the SET ENVIRONMENT statement are mutually exclusive. After you issue the SET ENVIRONMENT SELECT\_GRID\_ALL or SET ENVIRONMENT SELECT\_GRID statement, issuing a different option of either statement in the same session replaces whatever the previous ENVIRONMENT SELECT\_GRID\_ALL or SET ENVIRONMENT SELECT\_GRID statement established as the server behavior for grid queries in the session.

## Restrictions on SELECT\_GRID\_ALL

Do not call the `ifx_gridquery_skipped_nodes()` function while the SELECT\_GRID\_ALL session environment variable is set to '*grid*' or to '*region*'.

The SELECT\_GRID\_ALL session environment option should not be set to '*grid*' or to '*region*' outside a grid context.

## Examples of setting SELECT\_GRID\_ALL

The following statement establishes a default grid called **escorial** for the current session, and instructs the database server to interpret all queries that include no GRID clause as UNION ALL grid queries for that grid:

```
SET ENVIRONMENT SELECT_GRID_ALL "escorial";
```

If **california** were the name of a region in the **escorial** grid, the next example would instruct the database server to interpret all queries that include no GRID clause as UNION ALL grid queries for the **california** region, rather than having the entire **escorial** grid as their scope:

```
SET ENVIRONMENT SELECT_GRID_ALL "california";
```

The following example overrides the effect of any previous SET ENVIRONMENT SELECT\_GRID\_ALL statement that established a default grid or a default region, and an implicit UNION ALL operator, as the scope of subsequent queries that include no GRID clause:

```
SET ENVIRONMENT SELECT_GRID_ALL DEFAULT;
```

The statement above restores the default behavior for processing queries in the session, so that the database interprets only SELECT statements that explicitly include the GRID clause as grid queries.

For more information about grid queries, see the [GRID clause on page 809](#) and the .

[GRID clause on page 809](#)

## STATCHANGE session environment option

Use the STATCHANGE environment option to specify a positive integer as a global percentage-of-change threshold for UPDATE STATISTICS operations in automatic mode. The setting restricts automatic UPDATE STATISTICS operations to stale or missing distributions in which at least that percentage of rows have changed since statistics were updated.

You can specify an integer percentage value in the range from 1 to 100 for the STATCHANGE session environment option, which has this syntax:

STATCHANGE environment option

**SET ENVIRONMENT STATCHANGE**

**DEFAULT** *'integer'*

| Element        | Description   | Restrictions  | Syntax  |
|----------------|---|---|---|
| <i>integer</i> | An unsigned integer value in the range 1 - 100 as a percentage of rows changed in a table or fragment since the most recent recalculation | Must be delimited between single (') or double (") quotation marks. The <b>DEFAULT</b> keyword applies the current <b>STATCHANGE</b> configuration parameter value. | <a href="#">Literal Number on page 1419</a><br><a href="#">asQuoted String on page 1424</a> |

## Usage

When automatic UPDATE STATISTICS operations are enabled, the database server can reset the value of the STATCHANGE session environment option as the threshold for recalculating distribution statistics in the current session when your SET ENVIRONMENT STATCHANGE statement specifies one of these values:

### *'integer' or "integer"*

Sets a data-change threshold, as a percentage of rows modified since distribution statistics were calculated, for automatic UPDATE STATISTICS operations on tables or fragments. The *integer* value (where `1` *'integer'* `100`) has no effect, however, except when the automatic statistics mode has been enabled by one of the mechanisms identified below at one of the following scopes:

- the UPDATE STATISTICS statement, if it includes the `AUTO` keyword
- the session, if the `AUTO_STAT_MODE` session option is `ON`
- the system default, if the `AUTO_STAT_MODE` configuration setting is `1`
- for the table, if its `STATCHANGE` table attribute is `AUTO`.

If the UPDATE STATISTICS statement includes the `FORCE` keyword, however, these STATCHANGE settings and attributes are ignored, and table statistics are recalculated, even if the most recently calculated distribution statistics for the table in the system catalog have not been changed by subsequent DML operations.

### **DEFAULT**

Applies the current setting of the `AUTO_STAT_MODE` configuration parameter to the current session. This automatic location and fragmentation during the current session.

- for all sessions, when the `AUTO_STAT_MODE` configuration parameter has enabled the automatic mode,
- or for only the current session, when the SET ENVIRONMENT `AUTO_STAT_MODE` statement of SQL has enabled the automatic mode.

## Automatic UPDATE STATISTICS mode

In automatic mode, the database server selectively recalculates distribution statistics that already exist in the `sysdistrib` or `sysfragdist` system catalog tables only for stale distributions. The value that you set for STATCHANGE specifies criteria for determining whether the column distribution statistics of a table or a fragment qualify for an update.

When UPDATE STATISTICS is in automatic mode, but the STATCHANGE session environment option is not set, or is set to DEFAULT, the explicit or default setting of the STATCHANGE configuration parameter can specify a positive integer as a threshold to define stale data distributions. If the STATCHANGE configuration parameter is not set, the default value is 10. The database server compares this threshold to the actual percentage of rows that have been deleted, inserted, or modified by DML operations since the distribution statistics were most recently updated. Only if the actual percentage is equal to or greater than the threshold are distributions recalculated automatically.

You can use the SET ENVIRONMENT STATCHANGE statement, however, to specify an integer value that overrides the explicit or default STATCHANGE configuration parameter setting for the current session.

## Examples of SET ENVIRONMENT STATCHANGE

The following statement sets a threshold of 50 percent for the database server to use in determining if distribution statistics qualify for an update:

```
SET ENVIRONMENT STATCHANGE '50';
```

With a STATCHANGE threshold of 50 for the session, when automatic UPDATE STATISTICS operations are enabled, the column distributions of a table or fragment are recalculated only if half of all the rows have been processed by DML operations since the current values in the **sysdistrib** or **sysfragdist** system catalog tables were calculated.

Whether the granularity of distributions to be calculated in automatic mode is the entire table or is some of its fragments depends on the current STATLEVEL setting for the table, as described in the topics [Statistics options of the CREATE TABLE statement on page 395](#) and [Statistics options of the ALTER TABLE statement on page 163](#).

The following statement sets the threshold for the server to use to determine if distribution statistics qualify for an update to the current setting of the STATCHANGE configuration parameter:

```
SET ENVIRONMENT STATCHANGE DEFAULT;
```

You might use the **DEFAULT** option to restore a STATCHANGE threshold that the SET ENVIRONMENT STATCHANGE statement had reset because the session required an unusual STATCHANGE value for automatic UPDATE STATISTICS operations on a specific table.

The next example includes successive SQL statements that can affect whether distribution statistics are recalculated for the **customer** table:

```
SET ENVIRONMENT AUTO_STAT_MODE ON;
SET ENVIRONMENT STATCHANGE '25';
UPDATE STATISTICS HIGH FOR customer FORCE;
```

In this example,

- The first statement enables automatic statistics mode for the session.
- The second statement sets the change threshold at 25% for the current session.
- The UPDATE STATISTICS statement ignores the STATCHANGE setting for the session, and ignores the percentage of modified rows in the **customer** table, because the **FORCE** keyword requires the database server to recalculate distribution statistics for all columns in that table.

See also the topic [AUTO\\_STAT\\_MODE session environment option on page 912](#).

## USELASTCOMMITTED session environment option

The USELASTCOMMITTED session environment option can improve concurrency in sessions that use the Committed Read, Dirty Read, Read Committed, or Read Uncommitted isolation levels by reducing the risk of locking conflicts when two or more sessions attempt to access the same row in a table whose locking granularity is row-level locking.

The SET ENVIRONMENT USELASTCOMMITTED statement of SQL supports the following syntax:

USELASTCOMMITTED session environment option

```
SET ENVIRONMENT USELASTCOMMITTED '
COMMITTED READ DIRTY READ ALL NONE
'
```

## Usage

The SET ENVIRONMENT USELASTCOMMITTED statement can specify whether queries and other operations that encounter exclusive locks that other sessions hold while changing data values should use the most recently committed version of the data, rather than wait for the lock to be released.

This statement can override the **USELASTCOMMITTED** configuration parameter setting for the duration of the current session. You can use the SET ISOLATION statement to override the USELASTCOMMITTED session environment setting.

The USELASTCOMMITTED session environment option can have any one of four values:

### 'COMMITTED READ'

The database server reads the most recently committed version of the data when it encounters an exclusive lock while attempting to read a row in the Committed Read or Read Committed isolation level.

### 'DIRTY READ'

The database server reads the most recently committed version of the data if it encounters an exclusive lock while attempting to read a row in the Dirty Read or Read Uncommitted isolation level.

### 'ALL'

The database server reads the most recently committed version of the data if it encounters an exclusive lock while attempting to read a row in the Committed Read, Dirty Read, Read Committed, or Read Uncommitted isolation level.

### 'NONE'

This value disables the USELASTCOMMITTED feature that can access the last committed version of data in a locked row. Under this setting, if your session encounters an exclusive lock when attempting to read a row in the Committed Read, Dirty Read, Read Committed, or Read Uncommitted isolation level, your transaction cannot read that row until the concurrent transaction that holds the exclusive lock is committed or rolled back.

## Examples of SET ENVIRONMENT USELASTCOMMITTED

The following statements specify the Committed Read isolation mode and replace the explicit or default **USELASTCOMMITTED** configuration parameter setting with a setting that reads the most recently committed version of the data in rows on which concurrent readers hold an exclusive lock:

```
SET ISOLATION COMMITTED READ;
SET ENVIRONMENT USELASTCOMMITTED 'ALL';
```

By including the following statements within a **PUBLIC.sysdbopen** or **user.sysdbopen** procedure, specify at connection time the Committed Read isolation mode and replace the explicit or default **USELASTCOMMITTED** configuration parameter setting with a setting that reads the most recently committed version of the data in tables on which concurrent readers hold an exclusive lock:

```
SET ENVIRONMENT USELASTCOMMITTED 'COMMITTED READ';
```

Besides **sysdbopen( )**, any SPL routine can use these statements to specify the Committed Read Last Committed transaction isolation level during a session. These statements enable SQL operations that read data to use the last committed version when an exclusive lock is encountered during an operation that reads a table. This can avoid deadlock situations or other locking errors when another session is attempting to modify the same row or table. It does not reduce the risk of locking conflicts with other sessions that are writing to tables, or with concurrent DDL transactions that hold implicit or explicit locks on a user table or on a system catalog table.

In cross-server distributed queries, if the isolation level of the session that issued the query has the LAST COMMITTED isolation level option in effect, but one or more of the participating databases does not support this LAST COMMITTED feature, then the entire transaction conforms to the Committed Read or Dirty Read isolation level of the session that issued the transaction, without the LAST COMMITTED option enabled.

The next example enables the database server reads the most recently committed version in transactions where the isolation level is Dirty Read or Read Uncommitted:

```
SET ENVIRONMENT USELASTCOMMITTED 'DIRTY READ';
```

The following example disables the explicit or default **USELASTCOMMITTED** configuration parameter setting, so that in the Committed Read, Dirty Read, Read Committed, or Read Uncommitted isolation, DML operations that encounter exclusive locks during the session must wait until the lock is released before reading the last committed version of the row:

```
SET ENVIRONMENT USELASTCOMMITTED 'NONE';
```

### Restrictions on the USELASTCOMMITTED option

This session environment option is designed for operations on tables that use a locking granularity of ROW. For operations on tables with a locking granularity of TABLE, the USELASTCOMMITTED setting does not reduce the risk of locking conflicts when concurrent processes attempt to access the same tables.

For information about additional restrictions that can prevent a transaction from reading the most recently committed data from a table locked by another transaction while USELASTCOMMITTED is enabled, see [The LAST COMMITTED Option to Committed Read on page 977](#).

For more information about the USELASTCOMMITTED configuration parameter, see your .

## USE\_SHARDING session environment option

The USE\_SHARDING session environment option controls the scope of sharded queries.

The SET ENVIRONMENT USE\_SHARDING statement of SQL supports the following syntax:

USE\_SHARDING session environment option

**SET ENVIRONMENT USE\_SHARDING**

**ON OFF**

## Usage

When you enable the `USE_SHARDING` environment option, sharded queries run on all shard servers in the cluster. When the `USE_SHARDING` environment option is disabled, sharded queries are limited to the local database. For consistent sharded insert, update, and delete operations, sharded transactions are applied with the two phase commit protocol instead of being eventually consistent. Data is moved to the appropriate shard server before the transaction is committed. Consistent shard insert, update and delete operations also require that you set the `SHARD_ID` configuration parameter on each shard server.

You can automatically run the `SET ENVIRONMENT USE_SHARDING` statement when the session connects to a database by defining the `sysdbopen()` routine, for example:

```
CREATE PROCEDURE PUBLIC.SYSDBOPEN()
  SET ENVIRONMENT USE_SHARDING ON;
END PROCEDURE
```

---

### Related information

Session Configuration Procedures

## SHARDJOIN\_FALLBACK session environment option

Use `SHARDJOIN_FALLBACK` session environment option to create a local temporary table to pull the data from the shard participants.

The `SET ENVIRONMENT SHARDJOIN_FALLBACK` statement of SQL supports the following syntax:

`SHARDJOIN_FALLBACK` session environment option

**SET ENVIRONMENT SHARDJOIN\_FALLBACK**

**ON OFF**

### Usage

When you enable the `SHARDJOIN_FALLBACK`, IDS execute the sharded table joins by creating temporary tables locally and pull the data from the respective participants. This solution is sub-optimal but the query can be executed to its completion with out raising an error. The intention of this support is only to have a migration comfort and not an optimal scaling solution. The application might have to change their sharding scheme to match with the join criteria to achieve an optimal performance. Any other cases that can not be done even by the fallback mechanism are rejected.

## USE\_DWA session environment options

Use the `USE_DWA` session environment options of the `SET ENVIRONMENT` statement to control various aspects of workload analysis, data mart creation, and query acceleration by setting the database client environment for sessions. Each of the `USE_DWA` options has an effect only with .

The `USE_DWA` options of the `SET ENVIRONMENT` statement have this syntax:

- The `SESSION session_id` option is not valid in SET ENVIRONMENT USE\_DWA statements that also include the `PROBE CLEANUP` option
- The `SESSION session_id` option is not valid in SET ENVIRONMENT USE\_DWA statements within the `sysdbopen()` session configuration routine.

**ACCELERATE ON**

Enables query acceleration, so that subsequent queries that match one of the accelerated query tables (AQTs) are sent to the accelerator server for processing.

**ACCELERATE OFF**

Disables query acceleration, so that subsequent queries are not sent to the accelerator server, even if the queries meet the required AQT criteria.

**DEBUG ON**

Turns on debugging. This option has an effect during workload analysis and during query acceleration, when either the `ACCELERATE ON` or the `PROBE START` option of the SET ENVIRONMENT USE\_DWA statement is already in effect for the current session. The default log file for query acceleration debugging is the `online.log` file, as specified by the `MSGPATH` configuration parameter.

**DEBUG OFF**

Turns off debugging.

**DEBUG FILE**

This option has an effect when either or both of the `ACCELERATE ON` or the `PROBE START` option of the SET ENVIRONMENT USE\_DWA statement is already in effect.

**DEBUG FILE *file\_name***

Makes the specified file the log file for subsequent query acceleration debugging in the current session. This replaces the default `online.log` file, as specified by the `MSGPATH` configuration parameter, or replaces a nondefault log file from a previous SET ENVIRONMENT USE\_DWA 'DEBUG FILE *file\_name*' statement. This option has an effect when either the `ACCELERATE ON` or the `PROBE START` option of the SET ENVIRONMENT USE\_DWA statement is already in effect, and the path and the *file\_name* include no special characters.

**FALLBACK ON**

If cannot accelerate subsequent queries, the queries are processed by the Informix® database server. For example, the accelerator server is offline, or the queries do not match one of the accelerated query tables (AQTs). This option has an effect during query acceleration, when the `ACCELERATE ON` option of the SET ENVIRONMENT USE\_DWA statement is already in effect.

**FALLBACK OFF**

If cannot accelerate subsequent queries, the queries are not processed by the Informix® database server. This option has an effect when the `ACCELERATE ON` option of the SET ENVIRONMENT USE\_DWA statement is already in effect.

**PROBE START**

Activates query probing. Query probing is gathering information about query workload. Query probing is used in workload analysis to create a data mart definition.

**PROBE STOP**

Deactivates query probing.

**LOADPDQ resources**

Controls the PDQPRIORITY setting for the database sessions that extract data from the database tables during a data mart load operation.

This setting is effective for full data mart load, partition load and refresh mart.

The PDQPRIORITY is used with the MAX\_PDQPRIORITY configuration parameter to calculate the effective PDQ priority for the data extraction database sessions.

The default PDQPRIORITY for data extraction database sessions is 2.

**PROBE CLEANUP**

Removes from the database all probing data that any past and current query workload analysis produced in the database. The `SESSION` keyword option cannot be specified in the same `SET ENVIRONMENT USE_DWA` statement that includes the `PROBE CLEANUP` keywords.

**UNIQUECHECK ON**

Enables uniqueness checking for primary key columns and for unique constraint keys during the creation of a data mart. By default, uniqueness checking is enforced for data mart creation.

**UNIQUECHECK OFF**

Disables uniqueness checking This can be useful when creating a data mart that requires one-to-many references to a parent table in a database of a remote server instance, or one-to-many references to a parent table that the query specifies as a synonym for a view. In these contexts where the uniqueness of index key column values in the parent table cannot be validated, avoiding the uniqueness check can prevent failure-to-validate exceptions during data mart creation.

**Important:** For synonyms of tables in remote database server instances, and for views, information on the uniqueness of data values in key columns is not available while the data mart is being created. For these table objects, the `UNIQUECHECK OFF` setting enables you to create one-to-many references where the parent table is a synonym that references a remote table or a view. Because this check is skipped, the user is responsible for ensuring the uniqueness of data in the parent-key column(s) by other means. But if you create a one-to-many reference with nonunique data values in the key columns of the parent table, your accelerated queries will return incorrect results.

## Examples of setting USE\_DWA environment options

The following example turns on query acceleration for the current session.

```
SET ENVIRONMENT USE_DWA 'ACCELERATE ON';
```

As for all USE\_DWA options, double ( " ) quotation-mark delimiters are also valid, as in this statement that has the same effect of turning on query acceleration:

```
SET ENVIRONMENT USE_DWA "ACCELERATE ON";
```

The following example removes all the probing data that was previously collected for the current database.

```
SET ENVIRONMENT USE_DWA 'PROBE CLEANUP';
```

The following example turns on acceleration and turns off fallback. The queries are not processed by the Informix® database server. Queries that cannot be accelerated by will fail.

```
SET ENVIRONMENT USE_DWA 'ACCELERATE ON';
SET ENVIRONMENT USE_DWA 'FALLBACK OFF';
```

The following example activates the debug option. By default, the debug information is appended to the `online.log` file.

```
SET ENVIRONMENT USE_DWA 'DEBUG ON';
```

The following example creates probing data for your queries, turns on debugging, and appends the debugging information to a file named `/tmp/my_debug_file`.

```
SET ENVIRONMENT USE_DWA 'PROBE START';
SET ENVIRONMENT USE_DWA 'DEBUG ON';
SET ENVIRONMENT USE_DWA 'DEBUG FILE /tmp/my_debug_file';
```

The following example turns on debugging. The debug output of query 1 is written to the file `/tmp/myDwaDebugFile`. The debug output of query 2 is written to the default `online.log` file.

```
SET ENVIRONMENT USE_DWA 'DEBUG ON';
SET ENVIRONMENT USE_DWA 'DEBUG FILE /tmp/myDwaDebugFile';
SELECT ... { query 1 }
SET ENVIRONMENT USE_DWA 'DEBUG FILE';
SELECT ... { query 2 }
```

The following example turns on query acceleration for user session 64.

```
SET ENVIRONMENT USE_DWA 'SESSION 64 ACCELERATE ON';
```

This `SESSION` example of USE\_DWA would not be valid in a `sysdbopen()` session configuration routine. The DBSA or user **informix** can issue the `onstat -g ses` command to display the `session_id` identifying numbers of all the currently running user sessions.

The following example deactivates query probing for session 32, and removes from the current database all probing data that past and current query workload analysis produced.

```
SET ENVIRONMENT USE_DWA "SESSION 32 PROBE";
SET ENVIRONMENT USE_DWA "PROBE CLEANUP";
```

The following example turns off validating the uniqueness of data values in key columns during data mart creation within session 64.

```
SET ENVIRONMENT USE_DWA 'SESSION 64 UNIQUECHECK OFF';
```

For more information about support for workload analysis, data marts, accelerated query tables, and installing and configuring the accelerator server, see the .

## USTLOW\_SAMPLE environment option

Use the USTLOW\_SAMPLE session environment option to enable or disable sampling during the collection of index statistics for UPDATE STATISTICS LOW operations in the current session.

By default, when the UPDATE STATISTICS statement gathers distribution statistics for a table on which one or more indexes are defined, the database server reads all index leaf pages in sequence to calculate index statistics, such as the number of leaf pages, the number of unique lead index-key values, and cluster information.

For an index with more than 100 KiB leaf pages, estimating these index statistics from sampling can increase the speed of the UPDATE STATISTIC LOW operation.

To set the USTLOW\_SAMPLE session environment variable, specify:

- '0' or OFF to disable sampling
- '1' or ON to enable sampling

The value that you specify overrides the setting of the USTLOW\_SAMPLE configuration parameter for the session.

For example, to enable sampling for index statistics in the current session, use either of the following statements:

```
SET ENVIRONMENT USTLOW_SAMPLE '1';  
SET ENVIRONMENT USTLOW_SAMPLE ON;
```

You cannot control how much data is in the sample.

---

## SET EXPLAIN statement

Use the SET EXPLAIN statement to enable or disable the recording measurements of queries in the current session, including the plan of the query optimizer, an estimate of the number of rows returned, and the relative cost of the query.

**Syntax****SET EXPLAIN****OFF****ON****AVOID\_EXECUTE****FILE TO***expression*'*file\_name*'*file\_name\_var*

| Element              | Description  | Restrictions   | Syntax                                     |
|----------------------|--|--|--|
| <i>expression</i>    | Expression that returns a file name specification  | Must return a string satisfying the restrictions on the file name  | <a href="#">Expression on page 1193</a>    |
| <i>file_name</i>     | The explain output file name. If the file's absolute path is not included, the explain output file will be created in the default explain output file location | Must conform to operating-system rules. If the file already exists, explain output will be appended to it. | <a href="#">Quoted String on page 1424</a> |
| <i>file_name_var</i> | Host variable that stores a file name  | Must be a character data type  | Language specific                          |

**Usage**

Output from a SET EXPLAIN ON statement is directed to the appropriate file until you issue a SET EXPLAIN OFF statement or until the program ends. If you do not enter a SET EXPLAIN statement, then the default behavior is OFF, and the database server does not generate measurements for queries.

The SET EXPLAIN statement executes during the database server optimization phase, which occurs when you initiate a query. For queries that are associated with a cursor, if the query is prepared and does not have host variables, optimization occurs when you prepare it. Otherwise, optimization occurs when you open the cursor.

The SET EXPLAIN statement provides various measurements of the work involved in performing a query.

**Option****Effect****ON**

Generates measurements for each subsequent query and writes the results to an output file in the current directory. If the file already exists, new output is appended to the existing file.

**AVOID\_EXECUTE**

Prevents a SELECT, INSERT, MERGE, UPDATE, or DELETE statement from executing. The database server prints the query plan to an output file

**OFF**

Terminates activity of the SET EXPLAIN statement, so that measurements for subsequent queries are no longer generated or written to the output file

**FILE TO**

Generates measurements for each subsequent query and allows you to specify the location for the explain output file.

The following example writes the query plan in the explain output file for subsequent queries in the current session:

```
SET EXPLAIN ON;
```

The following example suspends writing query plans to a file in the current session:

```
SET EXPLAIN OFF;
```

[Default name and location of the output file on Windows on page 966](#)

## Using the AVOID\_EXECUTE Option

The AVOID\_EXECUTE keyword prevents DML statements from executing. Instead, the database server prints the query plan to an output file.

The SET EXPLAIN ON AVOID\_EXECUTE statement activates the Avoid Execute option for a session, or until the next SET EXPLAIN OFF (or ON) without AVOID\_EXECUTE. If you activate AVOID\_EXECUTE for a query that contains a remote table, the query does not execute at either the local or remote site.

The following example stores the output in the specified file.

```
SET EXPLAIN ON AVOID_EXECUTE;
SET EXPLAIN FILE TO '/tmp/explain.out';
```

When AVOID\_EXECUTE is set, the database server sends a warning message. If you are using DB-Access, it displays a text message

```
Warning! avoid_execute has been set
```

for any select, delete, update or insert query operations. From ESQL, the **sqlwarn.sqlwarn7** character is set to 'W'.

Use the SET EXPLAIN ON or the SET EXPLAIN OFF statement to turn off the AVOID\_EXECUTE option. The SET EXPLAIN ON statement turns off the AVOID\_EXECUTE option but continues to generate a query plan and writes the results to an output file.

If you issue the SET EXPLAIN ON AVOID\_EXECUTE statement in an SPL routine, the SPL routine and any DDL statements still execute, but the DML statements inside the SPL routine do not execute. The database server prints the query plan of the SPL routine to an output file. To turn off this option, you must execute the SET EXPLAIN ON or the SET EXPLAIN OFF statement outside the SPL routine. If you execute the SET EXPLAIN ON AVOID\_EXECUTE statement before you execute an SPL routine, the DML statements inside the SPL routine do not execute, and the database server does not print a query plan of the SPL routine to an output file.

Nonvariant functions in a query are still evaluated when AVOID\_EXECUTE is in effect, because the database server calculates these functions before optimization.

For example, the **func()** function is evaluated, even though the following SELECT statement is not executed:

```
SELECT * FROM orders WHERE func(10) > 5;
```

For other performance implications of the AVOID\_EXECUTE option, see your *Informix® Performance Guide*.

If you execute the SET EXPLAIN ON AVOID\_EXECUTE statement before you open a cursor in the Informix® ESQL/C program, each FETCH operation returns the message that the row was not found. If you execute SET EXPLAIN ON AVOID\_EXECUTE after the Informix® ESQL/C program opens a cursor, however, this statement has no effect on the cursor, which continues to return rows.

## Using the FILE TO option

When you execute a SET EXPLAIN FILE TO statement, explain output is turned on. The SET EXPLAIN FILE TO statement can change the default file name for the explain output until the end of the session or until another SET EXPLAIN statement is issued.

The filename can be any valid combination of path and file name. If no path component is specified, the file is placed in the default explain output location. The permissions for the file are owned by the current user.

The output file that you specify in the SET EXPLAIN statement can be a new file or an existing file. If the FILE TO clause specifies an existing file, the new output is appended to that file.

### Related information

[Default name and location of the explain output file on UNIX on page 965](#)

[Default name and location of the output file on Windows on page 966](#)

## Default name and location of the explain output file on UNIX™

When you issue the SET EXPLAIN ON statement, the plan that the optimizer chooses for each subsequent query is written to the explain output file.

If the explain output file does not exist when you issue SET EXPLAIN ON, the database server creates the file. If the explain output file already exists when you issue the SET EXPLAIN ON statement, subsequent output is appended to the file.

### Default name of the explain output file

Explain output files generated by a SET EXPLAIN statement and explain files generated by onmode -Y have different default names. Explain output filenames for mapped users are different than the explain output filenames for OS users, as well. The following table shows the default names:

**Table 14. Default explain output file names.**

| User and generation type     | File name                                |
|------------------------------|--|
| Regular user and SET EXPLAIN | sqexplain.out                            |
| Mapped user and SET EXPLAIN  | <i>username_sqexplain.out</i>            |
| Regular user and onmode -Y   | sqexplain.out. <i>session_id</i>         |
| Mapped user and onmode -Y    | <i>username_sqexplain.out.session_id</i> |

### Default location of the explain output file

If the client application and the database server are on the same computer, the output file is stored in your current directory. If you are using a version 5.x or earlier client application and the output file does not appear in the current directory, check your home directory for the file. When the current database is on another computer, the output file is stored in your home directory on the remote host.

For a mapped user without a home directory, the explain output file is stored in `$INFORMIXDIR/users/server_svrnum/uid_uid`.

For a mapped user with a home directory, remote clients' explain output files are stored in the user's home directory, and local clients' explain output files are stored in the user's current working directory.

#### Related information

[Using the FILE TO option on page 965](#)

## Default name and location of the output file on Windows™

On Windows™, SET EXPLAIN ON writes the plan that the optimizer chooses for each subsequent query to a file in `%INFORMIXDIR%\sqexpln`.

For explain output files generated by the SET EXPLAIN statement, the default file name is `user_name.out`, where `user_name` is the user login.

For explain output files generated by onmode -Y, the default file name is `sqexplain.out.session_id`.

**Related reference**[SET EXPLAIN statement on page 962](#)**Related information**[Using the FILE TO option on page 965](#)

## SET EXPLAIN output

View the SET EXPLAIN output file to analyze information on an executed query, including the directives set for the query, an estimate of the cost of the query, an estimate of the number of returned rows, the order in which the server accessed tables, index keys, join methods, and query statistics.

The following table lists terms that can appear in the output file and their significance.

**Table 15. Output file terms**

| Term                | Significance   |
|---------------------|--|
| Query               | <p>Displays the executed query and indicates whether SET OPTIMIZATION was set to HIGH or LOW. If you SET OPTIMIZATION to LOW, the output displays the following uppercase string as the first line: <code>QUERY: {LOW}</code></p> <p>If you SET OPTIMIZATION to HIGH, the output of SET EXPLAIN displays the following uppercase string as the first line: <code>QUERY:</code></p>   |
| Directives followed | <p>Lists the directives set for the query</p> <p>If the syntax for a directive is incorrect, the query is processed without the directive. In that case, the output shows <code>DIRECTIVES NOT FOLLOWED</code> in addition to <code>DIRECTIVES FOLLOWED</code>.</p> <p>For more information on the directives specified after this term, see the <a href="#">Optimizer Directives on page 1472</a> or <a href="#">SET OPTIMIZATION statement on page 985</a>.</p> <p>If a DELETE or UPDATE statement specifies an uncorrelated subquery in the WHERE clause, the set of qualifying rows returned by the subquery is materialized as a temporary table, and the output of SET EXPLAIN displays within parentheses the following message: <code>(Temp Table For Subquery)</code></p> |
| Estimated cost      | <p>An estimate of the amount of work for the query</p> <p>The optimizer uses an estimate to compare the cost of one path with another. The estimate is a number the optimizer assigns to the selected access method. This number does not translate directly into time and cannot be used to compare different queries. It can be used, however, to compare changes made for the same query. When data distributions are used, a query with a higher estimate generally takes longer to run than one with a smaller estimate.</p>  |

**Table 15. Output file terms (continued)**

| Term                              | Significance  |
|-----------------------------------|---|
|                                   | In the case of a query and a subquery, two estimated cost figures are returned; the query figure also includes the subquery cost. The subquery cost is shown so that you can see the cost that is associated with only the subquery.  |
| Estimated number of rows returned | An estimate of the number of rows to be returned<br>This number is based on information in the system catalog tables.   |
| Numbered list                     | The order in which tables are accessed, followed by the access method used (index path or sequential scan)<br><br>When a query involves table inheritance, all the tables are listed under the supertable in the order in which they were accessed.   |
| Index name                        | The name of the index<br><br>For example, <code>idx1</code> is the name of the following index:<br><br><code>Index Name: informix.idx1</code><br><code>FOT</code> in the index name identifies the index as a forest of trees index: For example, the following index is a forest of trees index:<br><br><code>Index Name: informix.fot_idx (FOT)</code>  |
| Index keys                        | The columns used as filters or indexes; the column name used for the index path or filter is indicated.<br><br>The notation ( <i>Key Only</i> ) indicates that all the desired columns are part of the index key, so a key-only read of the index could be substituted for a read of the actual table. In databases that have the NLSCASE INSENSITIVE property, all index scan methods (except key-only scans) allow the query execution plan to map all case-sensitive values to a single value for NCHAR and NVARCHAR columns. For more on NLSCASE INSENSITIVE databases, see <a href="#">Duplicate rows in NLSCASE INSENSITIVE databases on page 779</a> .<br><br>The <i>Lower Index Filter</i> shows the key value where the index read begins; and the <i>Upper Index Filter</i> is shown for the key value where the index read stops. The <i>Index Key Filters</i> show filters that will be applied on retrieved index key values. If the query uses an index self-join path, the <i>Index Self Join Keys</i> shows the leading index key columns used as self-join keys, and the <i>Lower bound</i> and <i>Upper bound</i> show the boundaries of the leading index key columns. |
| Join method                       | When the query involves a join between two tables, the join method that the optimizer used (Nested Loop or Dynamic Hash) is shown at the bottom of the output for that query.<br><br>When the query involves a dynamic join of two tables, if the output contains the words <i>Build Outer</i> , the hash table is built on the first table listed (called the build table). If the words <i>Build Outer</i> do not appear, the hash table is built on the second table listed.   |

**Table 15. Output file terms (continued)**

| Term             | Significance  |
|------------------|---|
| Query statistics | When the EXPLAIN_STAT configuration parameter is set to 1, this section shows the number of rows returned, the number of rows estimated in the query plan, the time required, calls to iterator functions, and the estimated cost of scan and join operations on table objects. |
| Time             | When the output displays the elapsed time for a query execution plan or for a component of that plan, the value is formatted as <code>minutes:seconds.fraction</code> to display the minutes, seconds, and fractional part of a second.   |

If the query uses a collating order other than the default for the **DB\_LOCALE** setting, then the **DB\_LOCALE** setting and the name of the other locale that is the basis for the collation in the query (as specified by the SET COLLATION statement) are both included in the output file. Similarly, if an index is not used because of its collation, the output file indicates this.

## Complete-Connection Level Settings and Output Examples

The SET EXPLAIN statement supports *complete-connection level* settings.

The SET EXPLAIN statement supports *complete-connection level* settings. This means that values in the local session environment at the time of connection are propagated to all new or resumed transactions of the following types:

- transactions within the local database
- distributed transactions across databases of the same server instance
- distributed transactions across databases of two or more database server instances
- global transactions with XA-compliant data sources that are registered in the local database

If you change the SET EXPLAIN setting within a transaction, the new value is propagated back to the local environment and also to all subsequent new or resumed transactions.

### Examples of SET EXPLAIN Output

The following SQL statements cause the database server to write the query plans of the UPDATE statement (and of its subquery) to the default explain output file:

```
DATABASE stores_demo;
SET EXPLAIN ON;
```

```

UPDATE orders SET ship_charge = ship_charge + 2.00
  WHERE customer_num IN
    (SELECT orders.customer_num FROM orders
     WHERE orders.ship_weight < 50);
CLOSE DATABASE;

```

The following information is displayed in the resulting output:

```

QUERY:
-----
update orders set ship_charge = ship_charge + 2.00
where customer_num in
(select orders.customer_num from orders where
  orders.ship_weight < 50)

Estimated Cost: 4
Estimated # of Rows Returned: 8

1) informix.orders: INDEX PATH

(1) Index Keys: customer_num (Serial, fragments: ALL)
  Lower Index Filter: informix.orders.customer_num = ANY

Subquery:
-----
Estimated Cost: 2
Estimated # of Rows Returned: 8
(Temp Table For Subquery)

1) informix.orders: SEQUENTIAL SCAN

Filters: informix.orders.ship_weight < 50.00

```

The next example is based on the following SQL statements, which include a DELETE operation:

```

DATABASE stores_demo;
SET EXPLAIN ON;
DELETE FROM catalog WHERE stock_num IN
  (SELECT stock.stock_num FROM stock, catalog WHERE
   stock.stock_num = catalog.stock_num
   AND stock.unit_price < 50);
CLOSE DATABASE;

```

Below is the resulting output:

```

QUERY:
-----
DELETE FROM catalog WHERE stock_num IN
  (SELECT stock.stock_num from stock, catalog
   WHERE stock.stock_num = catalog.stock_num
   AND stock.unit_price < 50);

Estimated Cost: 19
Estimated # of Rows Returned: 37

1) ajay.catalog: INDEX PATH

(1) Index Keys: stock_num manu_code (Serial, fragments: ALL)
  Lower Index Filter: ajay.catalog.stock_num = ANY

```

```

Subquery:
-----
Estimated Cost: 12
Estimated # of Rows Returned: 44
(Temp Table For Subquery)

1) ajay.stock: SEQUENTIAL SCAN

    Filters: ajay.stock.unit_price < $50.00

2) ajay.catalog: INDEX PATH

    (1) Index Keys: stock_num manu_code
        (Key-Only) (Serial, fragments: ALL)
        Lower Index Filter:
            ajay.stock.stock_num = ajay.catalog.stock_num

```

NESTED LOOP JOIN

## External Table Operations in SET EXPLAIN Output

The Query Statistics section of SET EXPLAIN output provides information on operations that are loading data from or unloading data to an external table.

The following codes in the Query Statistics section of the SET EXPLAIN output file provides information on external tables:

- `xlcnv` identifies an operation that is loading data from an external table and inserting the data into a base table. Here `x` = external table, `l` = loading, and `cnv` = converter
- `xucnv` identifies an operation that is reading data from the base table and writing to the file that the external table is pointing to. Here `x` = external table, `u` = unloading, and `cnv` = converter

### Example

#### Examples

The following example shows a query in which an operating is loading data from an external table and inserting the data into a base table:

```
QUERY: (OPTIMIZATION TIMESTAMP: 11-11-2009 12:55:20)
```

```
-----
```

```
insert into items select * from ext_items
```

```
Estimated Cost: 5
```

```
Estimated # of Rows Returned: 68
```

```
1) informix.ext_items: SEQUENTIAL SCAN
```

```
Query statistics:
```

```
-----
```

```
Table map :
```

```
-----
```

```
Internal name      Table name
```

```
-----
```

```
t1                 items
```

```
type      it_count  time
```

```
-----
```

```
xlread   1          00:00.00
```

```
type      it_count  time
```

```
-----
```

```
xlcnv    67         00:00.00
```

```
type      table  rows_ins  time
```

```
-----
```

```
insert   t1      67         00:00.00
```

The following example shows a query in which an operating is loading data from an external table and inserting the data into a base table:

```
QUERY: (OPTIMIZATION TIMESTAMP: 11-11-2009 12:47:55)
```

```
-----
```

```
select * from orders into external ord_ext
using (datafiles ('disk:/tmp/ord'))
```

```
Estimated Cost: 2
```

```
Estimated # of Rows Returned: 23
```

```
1) informix.orders: SEQUENTIAL SCAN
```

```
Query statistics:
```

```
-----
```

```
Table map :
```

```
-----
```

```
Internal name      Table name
```

```
-----
```

```
t1                 orders
```

```
type      table  rows_prod  est_rows  rows_scan  time          est_cost
```

```
-----
```

```
scan     t1      23          23        23         00:00.00     3
```

```

type      it_count  time
-----
xucnv     23         00:00.00

type      it_count  time
-----
xuwrite   23         00:00.00

```

## SET INDEXES statement

Use the SET INDEXES statement to enable or disable a user-defined index, or to change the filtering mode of a unique index.

This statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

#### SET INDEXES

, *index*

FOR *table*

ENABLED DISABLED

<sup>454</sup> FILTERING

WITH ERROR WITHOUT ERROR

<sup>455</sup>

| Element      | Description   | Restrictions | Syntax                                  |
|--------------|---|--------------|---|
| <i>index</i> | Index to be enabled, disabled, or changed in its filtering mode                         | Must exist   | <a href="#">Identifier on page 1456</a> |
| <i>table</i> | Table whose indexes are all to be enabled, disabled, or changed in their filtering mode | Must exist   | <a href="#">Identifier on page 1456</a> |

### Usage

You can use this statement to enable or disable a specific index or a list of indexes. You can also use the *table* option to enable or disable all of the user-defined indexes on a table without specifying their individual identifiers. For example, the next two examples respectively disable and enable all of the indexes on the **cust\_calls** table:

```

SET INDEXES FOR cust_calls DISABLED;
SET INDEXES FOR cust_calls ENABLED;

```

This simple syntax can be convenient in operations where you intend to LOAD or TRUNCATE all the data in a table, or to consolidate the free space in a table.

### Explicitly-defined and implicitly-defined indexes

The SET INDEXES statement operates on indexes that the CREATE INDEX statement created explicitly. It is not useful, however, with system-defined indexes that PRIMARY KEY or FOREIGN KEY constraint definitions create implicitly. The SET INDEXES statement cannot specify system-generated names that begin with the blank (ASCII 32) character, even if your

454. Unique indexes only

455. See [Filtering Modes on page 881](#)

database has the **DELIMITED** environment variable set to support double quotation marks as delimiters for database object identifiers.

To enable or disable implicitly-defined indexes, use instead the SET CONSTRAINTS statement, whose FOR *table* option can reference system-generated constraints implicitly, as in the following examples:

```
SET CONSTRAINTS FOR cust_calls DISABLED;  
SET CONSTRAINTS FOR cust_calls ENABLED;
```

To disable all the explicitly-defined and implicitly-defined indexes of a table, use the FOR *table* options of both the SET INDEXES and SET CONSTRAINTS statements, as in the following examples:

```
SET INDEXES FOR cust_calls DISABLED;  
SET CONSTRAINTS FOR cust_calls DISABLED;
```

You can similarly enable all the explicitly-defined and implicitly-defined indexes of a table, without referencing the system-generated names of the implicitly-defined indexes, by substituting **ENABLED** for **DISABLED** in the examples above.

The SET INDEXES statement is a special case of the SET Database Object Mode statement. The SET Database Object Mode statement can also enable or disable a trigger or constraint, or can change the filtering mode of constraints and unique indexes.

For the complete syntax and semantics of the SET INDEXES statement, see [SET Database Object Mode statement on page 871](#).

Do not confuse the SET INDEXES statement with the SET INDEX statement, which was supported in releases earlier than Version 9.40. The Informix® database server ignores the SET INDEX statement in current releases.

## Restrictions on Secondary Servers

In cluster environments, the SET INDEXES statement is not supported on updatable secondary servers. (More generally, session-level index, trigger, and constraint modes that the SET Database Object Mode statement specifies are not redirected for UPDATE operations on table objects in databases of secondary servers.)

---

### Related reference

[SET CONSTRAINTS statement on page 869](#)

## SET ISOLATION statement

Use the SET ISOLATION statement to define the degree of concurrency among processes that attempt to access the same rows simultaneously.

This statement is an extension to the ANSI/ISO standard for SQL.

**Syntax**

**SET ISOLATION TO**  
**REPEATABLE READ**  
**COMMITTED READ LAST COMMITTED**  
**CURSOR STABILITY**  
**DIRTY READ**  
**WITH WARNING**  
**RETAIN UPDATE LOCKS**

**Usage**

The SET ISOLATION statement is the Informix® extension to the ANSI SQL-92 standard. The SET ISOLATION statement can change the enduring isolation level for the session. If you want to set isolation levels through an ANSI-compliant statement, use the SET TRANSACTION statement instead. For a comparison of these two statements, see [SET TRANSACTION statement on page 1003](#).

The TO keyword is optional, and has no effect.

SET ISOLATION provides the same functionality as the ISO/ANSI-compliant SET TRANSACTION statement for isolation levels of DIRTY READ (called UNCOMMITTED in SET TRANSACTION), COMMITTED READ, and REPEATABLE READ (called SERIALIZABLE in SET TRANSACTION).

The database *isolation\_level* affects read concurrency when rows are retrieved from the database. The isolation level specifies the phenomena that can occur during execution of concurrent SQL transactions. The following phenomena are possible:

- **Dirty Read.** SQL transaction T1 modifies a row. SQL transaction T2 then reads that row before T1 performs a COMMIT. If T1 then performs a ROLLBACK, T2 will have read a row that was never committed, and therefore can be considered never to have existed.
- **Non-Repeatable Read.** SQL transaction T1 reads a row. SQL transaction T2 then modifies or deletes that row and performs a COMMIT. If T1 then attempts to reread that row, T1 might receive the modified value or discover that the row has been deleted.
- **Phantom Row.** SQL transaction T1 reads the set of rows N that satisfy some search condition. SQL transaction T2 then executes SQL statements that generate one or more new rows that satisfy the search condition used by SQL transaction T1. If T1 then repeats the original read with the same search condition, T1 receives a different set of rows.

The database server uses shared locks to support different levels of isolation among processes attempting to access data.

The update or delete process always acquires an exclusive lock on the row that is being modified. The level of isolation does not interfere with rows that you are updating or deleting. If another process attempts to update or delete rows that you are reading with an isolation level of Repeatable Read, that process is denied access to those rows.

In Informix® ESQL/C, cursors that are open when SET ISOLATION executes might or might not use the new isolation level when rows are retrieved. Any isolation level that was set from the time the cursor was opened until the application fetches a row might be in effect. The database server might have read rows into internal buffers and internal temporary tables using

the isolation level that was in effect at that time. To ensure consistency and reproducible results, close any open cursors before you execute the SET ISOLATION statement.

You can issue the SET ISOLATION statement from a client computer only after a database is opened.

---

[SET ENVIRONMENT statement on page 900](#)

## Complete-Connection Level Settings

The SET ISOLATION statement supports *complete-connection level* settings. This means that values in the local session environment at the time of connection are propagated to all new or resumed transactions. These can include the following types of transactions:

- transactions within the local database,
- distributed transactions across databases of the same server instance,
- distributed transactions across databases of two or more database server instances,
- global transactions with XA-compliant data sources that are registered in the local database.

If you change the isolation level within a transaction, the new value is propagated back to the local environment and also to all subsequent new or resumed transactions.

## Informix® Isolation Levels

The following definitions explain the critical characteristics of each isolation level, from the lowest level of isolation to the highest.

### Using the Dirty Read Isolation Level

Use the Dirty Read option to copy rows from the database whether or not there are locks on them. The program that fetches a row places no locks and it respects none. Dirty Read is the only isolation level available to databases that do not implement transaction logging.

This isolation level is most appropriate for static tables that are used for queries of tables where data is not being modified, because it provides no isolation. With Dirty Read, the program might return an uncommitted row that was inserted or modified within a transaction that has subsequently rolled back, or a *phantom row* that was not visible when you first

read the query set, but that materializes in the query set before a subsequent read within the same transaction. (Only the Repeatable Read isolation level prevents access to phantom rows. Only Dirty Read provides access to uncommitted rows from concurrent transactions that might subsequently be rolled back.)

The optional WITH WARNING keywords instruct the database server to issue a warning when DML operations that use the Dirty Read isolation level might return an uncommitted row or a phantom row. The transaction in the following example uses this isolation level:

```
BEGIN WORK;
SET ISOLATION TO DIRTY READ WITH WARNING;
...
COMMIT WORK;
```

The Dirty Read isolation level is sensitive to the current setting of the USELASTCOMMITTED configuration parameter and of the **USELASTCOMMITTED** session environment variable. For information about the behavior of the Dirty Read isolation level when either of these are set to `DIRTY READ` or to `ALL`, see [The LAST COMMITTED Option to Committed Read on page 977](#).

When you use High Availability Data Replication, the database server effectively uses Dirty Read isolation on the HDR Secondary Server, regardless of the specified SET ISOLATION or SET TRANSACTION isolation level, unless the UPDATABLE\_SECONDARY configuration parameter is enabled. For more information about this topic, see [Isolation Levels for Secondary Data Replication Servers on page 982](#).

## Using the Committed Read Isolation Level

Use the Committed Read option to guarantee that every retrieved row is committed in the table at the time that the row is retrieved. This option does not place a lock on the fetched row. Committed Read is the default level of isolation in a database with logging that is not ANSI compliant.

Committed Read is appropriate when each row is processed as an independent unit, without reference to other rows in the same table or in other tables.

---

[SET LOCK MODE statement on page 982](#)

## The LAST COMMITTED Option to Committed Read

Use the LAST COMMITTED keyword option of the Committed Read isolation level to reduce the risk of exclusive row-level locks held by other sessions either causing applications to fail with locking errors, or preventing applications from reading a locked row until after a concurrent transaction is committed or rolled back.

In contexts where an application attempts to read a row on which another session holds an exclusive lock, these keywords instruct the database server to return the most recently committed version of the row, rather than wait for the lock to be released.

This feature takes effect implicitly in all user sessions that use the Committed Read isolation level of the SET ISOLATION statement, or that use the Read Committed isolation level of the ANSI/ISO-compliant SET TRANSACTION statement, under any of the following circumstances:

- if the USELASTCOMMITTED configuration parameter is set to 'COMMITTED READ' or to 'ALL'
- if the SET ENVIRONMENT statement sets the USELASTCOMMITTED session environment variable to 'COMMITTED READ' or to 'ALL'.

This feature also takes effect implicitly in all user sessions that use the Dirty Read isolation level of the SET ISOLATION statement, or that use the Read Uncommitted isolation level of the ANSI/ISO-compliant SET TRANSACTION statement, under any of the following circumstances:

- if the USELASTCOMMITTED configuration parameter is set to 'DIRTY READ' or to 'ALL'
- if the SET ENVIRONMENT statement sets the USELASTCOMMITTED session environment variable to 'DIRTY READ' or to 'ALL'.

Enabling this feature cannot eliminate the possibility of locking conflicts, but they reduce the number of scenarios in which other sessions reading the same row can cause an error. The LAST COMMITTED keywords are only effective with concurrent read operations. They cannot prevent locking conflicts or errors that can occur when concurrent sessions attempt to write to the same row.

This feature has no effect on Committed Read or Dirty Read behavior in contexts where no last committed" version of the table is available, including these:

- The database does not support transaction logging
- The table was created with the LOCK MODE PAGE keywords, or has been altered to have a locking mode of PAGE
- The IFX\_DEF\_TABLE\_LOCKMODE environment variable is set to 'PAGE'
- The DEF\_TABLE\_LOCKMODE configuration parameter is set to 'PAGE'
- The LOCK TABLE statement has explicitly set an exclusive lock on the table
- An uncommitted DDL statement has implicitly set an exclusive lock on the table
- The table is a system catalog table on which an uncommitted DDL statement has implicitly set an exclusive lock
- The table has columns of complex data types or of user-defined data types
- The table is a RAW table
- A DataBlade® module is accessing the table
- The table was created using the Virtual Table Interface.

User-defined access methods are not required to support the LAST COMMITTED feature.

The scope of LAST COMMITTED semantics is neither statement-based nor transaction-based. This isolation level has the same instant-in-time scope that the Committed Read isolation level has without the LAST COMMITTED option. For example, when a query is executed twice within a single transaction with LAST COMMITTED in effect, different results might be returned by the same query, if other DML transactions that were operating on the same data are committed in the interval between the two submissions of the query. This instantaneous nature of the semantics of Committed Read and of Committed Read Last Committed exactly implements the ANSI/ISO Read Committed isolation level.

The LAST COMMITTED feature does not support reading through table-level locks. If the access plan for a query that uses the LAST COMMITTED feature encounters a table-level lock in a table or index that it needs to access, the query will return the following error codes:

**SQL error code:**

```
252: Cannot get system information for table.
```

**ISAM error code:**

```
113: ISAM error: the file is locked.
```

## Using the Cursor Stability Isolation Level

Use the Cursor Stability option to place a shared lock on the fetched row, which is released when you fetch another row or close the cursor. Another process can also place a shared lock on the same row, but no process can acquire an exclusive lock to modify data in the row. Such row stability is important when the program updates another table based on the data it reads from the row.

If you set the isolation level to Cursor Stability, but you are not using a transaction, the Cursor Stability acts like the Committed Read isolation level.

## Using the Repeatable Read Isolation Level

Use the Repeatable Read option to place a shared lock on every row that is selected during the transaction. Another process can also place a shared lock on a selected row, but no other process can modify any selected row during your transaction, nor insert a row that meets the search criteria of your query during your transaction. If you repeat the query during the transaction, you reread the same information. The shared locks are released only when the transaction commits or rolls back. Repeatable Read is the default isolation level in an ANSI-compliant database.

Repeatable Read isolation places the largest number of locks and holds them the longest. Therefore, it is the level that reduces concurrency the most.

## Default Isolation Levels

The default isolation level for a particular database is established when you create the database according to database type. The following list describes the default isolation level for each database type.

**Isolation Level**

**Database Type**

**Dirty Read**

Default level in a database without logging

### **Committed Read**

Default level in a logged database that is not ANSI compliant

### **Repeatable Read**

Default level in an ANSI-compliant database

The default level remains in effect until you issue a SET ISOLATION statement. After a SET ISOLATION statement executes, the new isolation level remains in effect until one of the following events occurs:

- You enter another SET ISOLATION statement.
- You open another database that has a default isolation level different from the level that your last SET ISOLATION statement specified.
- The program ends.

For a Informix® database that is not ANSI-compliant, unless you explicitly set the USELASTCOMMITTED configuration parameter, the LAST COMMITTED feature is not in effect for the default isolation levels. The SET ENVIRONMENT statement or the SET ISOLATION statement can override this default and enable LAST COMMITTED for the current session.

## **Using the RETAIN UPDATE LOCKS Option**

Use the RETAIN UPDATE LOCKS option to affect the behavior of the database server when it handles a SELECT ... FOR UPDATE statement.

In a database with the isolation level set to Dirty Read, Committed Read, or Cursor Stability, the database server places an update lock on a fetched row of a SELECT ... FOR UPDATE statement. When you turn on the RETAIN UPDATE LOCKS option, the database server retains the update lock until the end of the transaction rather than releasing it at the next subsequent FETCH or when the cursor is closed. This option prevents other users from placing an exclusive lock on the updated row before the current user reaches the end of the transaction.

You can use this option to achieve the same locking effects but avoid the overhead of dummy updates or the repeatable read isolation level.

You can turn this option on or off at any time during the current session.

You can turn the option off by resetting the isolation level without using the RETAIN UPDATE LOCKS keywords, as in the following example.

```
BEGIN WORK;  
SET ISOLATION TO  
  COMMITTED READ LAST COMMITTED RETAIN UPDATE LOCKS;  
...  
COMMIT WORK;  
BEGIN WORK;  
SET ISOLATION TO COMMITTED READ LAST COMMITTED ;  
...  
COMMIT WORK;
```

## **Controlling Update Locks through the Session Environment**

Another way to disable RETAIN UPDATE LOCKS behavior is to execute this SQL statement:

```
SET ENVIRONMENT RETAINUPDATELOCKS 'NONE';
```

This disables the RETAIN UPDATE LOCKS clause for the current transaction, and for any subsequent transactions of the same session, by resetting the RETAINUPDATELOCKS session environment variable.

The SET ENVIRONMENT RETAINUPDATELOCKS statement can also make the retention of update locks the default behavior for either the Committed Read, Cursor Stability, or Dirty Read isolation levels, or for all of these isolation levels, regardless of whether the SET ISOLATION statement includes the RETAIN UPDATE LOCKS clause.

For more information on update locks, see [RETAINUPDATELOCKS session environment option on page 945](#) and [Locking Considerations on page 1041](#).

## Turning the Option OFF During a Transaction

If you set the RETAIN UPDATE LOCKS option to OFF after a transaction has begun, but before the transaction has been committed or rolled back, several update locks might still exist.

Switching OFF the feature does not directly release any update lock. When you turn this option off, the database server reverts to normal behavior for the three isolation levels. That is, a FETCH statement releases the update lock placed on a row by the immediately preceding FETCH statement, and a closed cursor releases the update lock on the current row.

Update locks placed by earlier FETCH statements are not released unless multiple update cursors are present within the same transaction. In this case, a subsequent FETCH could also release older update locks of other cursors.

## Effects of Isolation Levels

You cannot set the transaction isolation level in a database that does not have logging. Every retrieval in such a database occurs as a Dirty Read.

The data retrieved from a BYTE or TEXT column can vary, depending on the transaction isolation level. Under Dirty Read or Committed Read levels of isolation, a process can read a BYTE or TEXT column that is either deleted (if the delete is not yet committed) or in the process of being deleted. Under these isolation levels, deleted data is readable under certain conditions. For information about these conditions, see the *Informix® Administrator's Guide*.

When you use DB-Access, as you use higher levels of isolation, lock conflicts occur more frequently. For example, if you use Cursor Stability, more lock conflicts occur than if you use Committed Read.

Using a scroll cursor in an ESQL/C transaction, you can force consistency between your temporary table and the database table either by setting the level to Repeatable Read or by locking the entire table during the transaction.

If you use a scroll cursor WITH HOLD in a transaction, you cannot force consistency between your temporary table and the database table. A table-level lock or locks that are set by Repeatable Read are released when the transaction is completed, but the scroll cursor with hold remains open beyond the end of the transaction. You can modify released rows as soon as the transaction ends, but retrieved data in the temporary table might be inconsistent with the actual data.

**Attention:** Do not use nonlogging tables within a transaction. If you need to use a nonlogging table within a transaction, either set the isolation level to Repeatable Read or else lock the table in Exclusive mode to prevent concurrency problems.

## Isolation Levels for Secondary Data Replication Servers

If the UPDATABLE\_SECONDARY configuration parameter is disabled (by being unset or by being set to zero), a secondary data replication server is read-only. In this case, only the Dirty Read or Read Uncommitted transaction isolation levels are available on High-Availability Data Replication (HDR) and Remote Standalone Secondary (RSS) servers.

If the UPDATABLE\_SECONDARY parameter is enabled (by being set to a valid number of connections greater than zero), a secondary data replication server can support the Read Committed, Committed Read, or Committed Read Last Committed transaction isolation level, with or without the USELASTCOMMITTED session environment variable of the SET ENVIRONMENT statement. Only the DELETE, INSERT, UPDATE, and MERGE statements of SQL (and the **dbexport** utility, if the STOP\_APPLY, USELASTCOMMITTED, and UPDATABLE\_SECONDARY configuration parameters are set) can support write operations on an updatable secondary server.

Shared Disk Secondary (SDS) servers, however, can support the Read Committed, Committed Read, Committed Read Last Committed isolation levels, regardless of their UPDATABLE\_SECONDARY setting. For more information about the UPDATABLE\_SECONDARY configuration parameter, see the HCL Informix® Administrator's Reference.

## SET LOCK MODE statement

Use the SET LOCK MODE statement to define how the database server handles a process that tries to access a locked row or table.

This statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

**SET LOCK MODE TO**

**NOT WAIT**

**WAIT**

*seconds*

| Element        | Description  | Restrictions                              | Syntax                                      |
|----------------|--|---|---|
| <i>seconds</i> | Maximum number of seconds that a process waits for a lock to be released before issuing an error | Valid only if shorter than system default | <a href="#">Literal Number on page 1419</a> |

### Usage

This statement can direct the response of the database server in the following ways when a process tries to access a locked row or table.

**Lock Mode****Effect****NOT WAIT**

Database server ends the operation immediately and returns an error code. This condition is the default.

**WAIT**

Database server suspends the process until the lock releases.

**WAIT seconds**

Database server suspends the process until the lock releases or until the waiting period ends. If the lock remains after the waiting period, the operation ends and an error code is returned.

For a description of the two distinct meanings of the term *lock mode* in this document, see Locking Granularity in the related concepts section.

To avoid waiting in operations that attempt to read rows on which concurrent sessions hold exclusive row-level locks, you can also use the LAST COMMITTED feature, either by setting it explicitly in the SET ISOLATION COMMITTED READ statement, or by setting the USELASTCOMMITTED configuration parameter or the USELASTCOMMITTED session environment option.

**Examples**

In the following example, the user specifies that if the process requests a locked row, the operation should end immediately and an error code should be returned:

```
SET LOCK MODE TO NOT WAIT;
```

In the following example, the user specifies that the process should be suspended until the lock is released:

```
SET LOCK MODE TO WAIT;
```

The next example sets an upper limit of 17 seconds on the length of any wait:

```
SET LOCK MODE TO WAIT 17;
```

---

**Related information**

[Locking Granularity on page 663](#)

[Using the Committed Read Isolation Level on page 977](#)

## WAIT Clause

The WAIT clause causes the database server to suspend the process until the lock is released or until a specified number of seconds have passed without the lock being released.

The database server protects against the possibility of a deadlock when you request the WAIT option. Before the database server suspends a process, it checks whether suspending the process could create a deadlock. If the database server discovers that a deadlock could occur, it ends the operation (overruling your instruction to wait) and returns an error code. In the case of either a suspected or actual deadlock, the database server returns an error.

Cautiously use the unlimited waiting period that was created when you specify the WAIT option without *seconds*. If you do not specify an upper limit, and the process that placed the lock somehow fails to release it, suspended processes could wait indefinitely. Because a true deadlock situation does not exist, the database server does not take corrective action.

In a network environment, the DBA uses the ONCONFIG parameter DEADLOCK\_TIMEOUT to establish a default value for *seconds*. If you use a SET LOCK MODE statement to set an upper limit, your value applies only when your waiting period is shorter than the system default.

## Complete-Connection Level Settings

The SET LOCK MODE statement supports *complete-connection level* settings. This means that values in the local session environment at the time of connection are propagated to all new or resumed transactions. These can include the following types of transactions:

- transactions within the local database,
- distributed transactions across databases of the same server instance,
- distributed transactions across databases of two or more database server instances,
- global transactions with XA-compliant data sources that are registered in the local database.

If you change the lock mode setting within a transaction, the new value is propagated back to the local environment and also to all subsequent new or resumed transactions.

In releases of Informix® earlier than 9.40.UC8, the SET LOCK MODE statement did not support complete-connection level settings. The process waited for the specified number of seconds only if you acquired locks within the current database server and a remote database server within the same transaction.

## SET LOG statement

Use the SET LOG statement to change your database logging mode from buffered transaction logging to unbuffered transaction logging or vice versa.

This statement is an extension to the ANSI/ISO standard for SQL. Unlike most extensions, the SET LOG statement is not valid in an ANSI-compliant database.

## Syntax

**SET**

**BUFFERED**

**LOG**

## Usage

You activate transaction logging when you create a database or add logging to an existing database. These transaction logs can be buffered or unbuffered.

Buffered logging is a type of logging that holds transactions in a memory buffer until the buffer is full, regardless of when the transaction is committed or rolled back. The database server provides this option to speed up operations by reducing the number of disk writes.

**Attention:** You gain a marginal increase in efficiency with buffered logging, but you incur some risk. In the event of a system failure, the database server cannot recover any completed transactions in the memory buffer that were not written to disk.

The SET LOG statement in the following example changes the transaction logging mode to buffered logging:

```
SET BUFFERED LOG;
```

Unbuffered logging is a type of logging that does not hold transactions in a memory buffer. As soon as a transaction ends, the database server writes the transaction to disk. If a system failure occurs when you are using unbuffered logging, you recover all completed transactions, but not those still in the buffer. The default condition for transaction logs is unbuffered logging.

The SET LOG statement in the following example changes the transaction logging mode to unbuffered logging:

```
SET LOG;
```

The SET LOG statement redefines the mode for the current session only. The default mode, which the database administrator sets with the **ondblog** utility, remains unchanged.

The buffering option does not affect retrievals from external tables. For distributed queries, a database with logging can retrieve only from databases with logging, but it makes no difference whether the databases use buffered or unbuffered logging.

An ANSI-compliant database cannot use buffered logging.

You cannot change the logging mode of ANSI-compliant databases. If you created a database with the WITH LOG MODE ANSI keywords, you cannot later use the SET LOG statement to change the logging mode to buffered or unbuffered transaction logging.

---

[CREATE DATABASE statement on page 201](#)

## SET OPTIMIZATION statement

Use the SET OPTIMIZATION statement to specify how much time the query execution optimizer spends developing a query plan or specifying optimization goals. The SET OPTIMIZATION statement is an extension to the ANSI/ISO standard for SQL

When you use **DB-Access** with Informix®, the ENVIRONMENT options to the SET OPTIMIZATION statement can define a general optimization environment for all statements in the current session.

### Syntax

#### SET OPTIMIZATION

#### HIGH LOW

#### FIRST\_ROWS ALL\_ROWS

<sup>456</sup>ENVIRONMENT Options <sup>457</sup>

### Usage

You can execute a SET OPTIMIZATION statement at any time. The specified optimization level carries across databases on the current database server. The option that you specify remains in effect until you issue another SET OPTIMIZATION statement or until the program ends. The default database server optimization level for the amount of time that the query optimizer spends determining the query plan is HIGH.

On Informix®, the default optimization goal is ALL\_ROWS. Although you can set only one option at a time, you can issue two SET OPTIMIZATION statements: one that specifies the time the optimizer spends to determine the query plan and one that specifies the optimization goal of the query.

Similarly, you can issue multiple SET OPTIMIZATION statements that include the ENVIRONMENT Options clause to specify a session environment for optimizing queries. In data warehousing applications, an appropriate optimizer environment can improve the performance of join queries of tables in a star schema. Optimizer environment settings persist until another SET OPTIMIZATION ENVIRONMENT statement overrides them, or until the session ends. For more information, see the [ENVIRONMENT Options on page 989](#) topic.

### Examples

The following example shows optimization across a network. The **central** database (on the **midstate** database server) is to have LOW optimization; the **western** database (on the **rockies** database server) is to have HIGH optimization.

```
CONNECT TO 'central@midstate';
SET OPTIMIZATION LOW;
SELECT * FROM customer;
CLOSE DATABASE;
CONNECT TO 'western@rockies';
SET OPTIMIZATION HIGH;
SELECT * FROM customer;
CLOSE DATABASE;
CONNECT TO 'wyoming@rockies';
SELECT * FROM customer;
```

456. DB-Access only

457. See [ENVIRONMENT Options on page 989](#)

Here the **wyoming** database is to have HIGH optimization because it resides on the same database server as the **western** database. The code does not need to re-specify the optimization level for the **wyoming** database because the **wyoming** database resides on the **rockies** database server like the **western** database.

The following example directs the Informix® optimizer to use the most time to determine a query plan, and to then return the first rows of the result as soon as possible:

```
SET OPTIMIZATION LOW;
SET OPTIMIZATION FIRST_ROWS;
SELECT lname, fname, bonus
FROM sales_emp, sales
WHERE sales.empid = sales_emp.empid AND bonus > 5,000
ORDER BY bonus DESC;
```

---

[SET ENVIRONMENT statement on page 900](#)

[UPDATE STATISTICS statement on page 1054](#)

[Optimizer Directives on page 1472](#)

[SET STATEMENT CACHE statement on page 999](#)

### Related information

[Performance considerations of UPDATE STATISTICS statements on page 1072](#)

## HIGH and LOW Options

The HIGH and LOW options determine how much time the query optimizer spends to determine the query plan:

- HIGH

This option directs the optimizer to use a sophisticated cost-based algorithm that examines all reasonable query-plan choices and selects the best overall alternative.

For large joins, this algorithm can incur more overhead than you desire. In extreme cases, you can run out of memory.

- LOW

This option directs the optimizer to use a less sophisticated but faster to design optimization algorithm, based on the lowest-cost path at each stage. This algorithm eliminates unlikely join strategies during the early stages of optimization and reduces the time and resources spent during optimization.

When you specify the LOW level of optimization, the database server might not select the optimal strategy because that strategy was eliminated from consideration during the early stages of the algorithm.

## FIRST\_ROWS and ALL\_ROWS Options

The `FIRST_ROWS` and `ALL_ROWS` keyword options identify two different query optimization goals:

- `FIRST_ROWS`

This option directs the optimizer to choose the query plan that returns the first qualifying record as soon as possible, ignoring plans that would sort records or create a hash table.

- `ALL_ROWS`

This option directs the optimizer to choose the query plan that returns all the qualifying records as quickly as possible.

### Inline optimizer directives

Rather than choosing either of these SET OPTIMIZATION statement options, you might instead specify an optimization-goal directive for an individual query as a comment immediately following the SELECT keyword that begins the query or subquery. For more information about the syntax and options for inline optimizer directives for queries in DELETE, SELECT, or UPDATE statements, see [Optimizer Directives on page 1472](#).

### External optimizer directives

Besides the query optimizer directives that the SET OPTIMIZATION statement can specify for queries in the current session, or the inline optimizer directives that can follow the SELECT keyword, the database server also supports a third format for influencing the choice of execution path by the query optimizer.

The DBA or user **informix** can execute the SAVE EXTERNAL DIRECTIVES statement to register *external optimizer directives*, also called *external directives*, in the sysdirectives table of the system catalog. If support for external directives has been enabled, the Informix® database server applies these directives automatically to queries that match a specified SELECT statement. The `ACTIVE`, `INACTIVE`, or `TEST ONLY` keyword options of SAVE EXTERNAL DIRECTIVES statements respectively enable, disable, or restrict the scope of an external directive.

Setting the EXT\_DIRECTIVES configuration parameter in the ONCONFIG file to `1` or `2`, and setting the IFX\_EXTDIRECTIVES client-side environment variable to `1` enables support for external directives.

Independent of the EXT\_DIRECTIVES configuration setting or the IFX\_EXTDIRECTIVES client-side settings, the SET ENVIRONMENT EXTDIRECTIVES setting of `'1'`, `on`, or `ON` for the session environment enables external optimizer directives in the current user session, if any active external directives are registered in the sysdirectives table.

The SET EXPLAIN output file displays whether external directives are in effect for a query.

For more information about external optimizer directives, see [Enabling or disabling external directives for a session on page 763](#).

## Optimizing SPL Routines

For SPL routines that remain unchanged or change only slightly, you might want to set the SET OPTIMIZATION statement to HIGH when you create the SPL routine. This step stores the best query plans for the SPL routine. Then execute a SET OPTIMIZATION LOW statement before you execute the SPL routine. The SPL routine then uses the optimal query plans and runs at the more cost-effective rate.

## ENVIRONMENT Options

Use the ENVIRONMENT Options clause of the SET OPTIMIZATION statement to define attributes of the optimization environment in the current session. These attributes persist until the session ends, or until another SET OPTIMIZATION ENVIRONMENT statement resets an optimization directive.

For some data warehousing applications, session environment settings that you specify in this clause can improve the performance of queries that join fact tables with dimension tables, in databases where the primary key of each dimension table corresponds to a foreign key of the fact table.

The **DB-Access** utility of Informix® supports the ENVIRONMENT Options clause of the SET OPTIMIZATION statement.

### Syntax

```
ENVIRONMENT
STAR_JOIN'
ENABLED DISABLED FORCED
'
FACT AVOID_FACT NON_DIM
'
, table
'
DEFAULT
"
```

| Element      | Description             | Restrictions               | Syntax                                  |
|--------------|-------------------------|----------------------------|---|
| <i>table</i> | Table, view, or synonym | Must exist in the database | <a href="#">Identifier on page 1456</a> |

### Usage

This syntax diagram is simplified, and does not show the double ( " ) quotation mark option for delimiters enclosing the list of one or more *table* objects, or enclosing the `DISABLED`, `ENABLED`, or `FORCED` keyword that you specify as the optimization environment setting.

**Important:** Do not use quotation marks to delimit the `STAR_JOIN`, `FACT`, `AVOID_FACT`, `NON_DIM`, or `DEFAULT` keywords. In the ENVIRONMENT Options clause, the `DEFAULT` keyword and the empty string ( `' '` or `" "` ) are equivalent.

The following table lists each ENVIRONMENT option, and describes their effect on whether the query optimizer considers star-join execution plans.

| Keywords                | Effect  | Optimizer Action  |
|-------------------------|---|---|
| <code>STAR_JOIN</code>  | The <code>'ENABLED'</code> setting turns on (and <code>'DISABLED'</code> turns off) star-join support for the current session. The <code>'FORCED'</code> setting favors a star-join execution path, when possible, for all queries  | For <code>'ENABLED'</code> , the optimizer considers the possibility of a star-join execution plan. For <code>'FORCED'</code> , a star-join plan will be chosen, if available. For <code>'DISABLED'</code> , star-join is not considered. |
| <code>FACT</code>       | Identifies tables that correspond to fact tables in a star schema. If an <code>AVOID_FACT</code> table is also specified in the same session as <code>FACT</code> , then <code>FACT</code> takes precedence. <code>DEFAULT</code> or an empty string turns off the <code>FACT</code> directive for the session. | Only tables in the <code>FACT</code> list are considered as fact tables in star-join optimization. Multiple tables can be listed as <code>FACT</code> .   |
| <code>AVOID_FACT</code> | Do not use the table (or any table in the list of tables) as a fact table in star-join optimization. <code>DEFAULT</code> or an empty string turns off the <code>AVOID_FACT</code> directive for the session.   | Tables in the <code>AVOID_FACT</code> list are not considered as fact tables in star-join optimization. Multiple tables can be listed as <code>AVOID_FACT</code> .  |
| <code>NON_DIM</code>    | Identifies tables that do not correspond to dimension tables in a star schema. <code>DEFAULT</code> or an empty string turns off the <code>NON_DIM</code> directive for the session.  | Tables in the <code>NON_DIM</code> list are not considered as dimension tables in star-join optimization. Multiple tables can be listed as <code>NON_DIM</code> .   |

Unless you explicitly set the `FACT`, `AVOID_FACT`, or `NON_DIM` optimizer directive to `DEFAULT`, a valid `SET OPTIMIZATION ENVIRONMENT` statement must include exactly one quoted string that defines an optimization environment setting. When the setting for the directive that follows the `ENVIRONMENT` keyword is not `DEFAULT`, a pair of single ( `'` ) or double ( `"` ) quotation mark symbols must delimit the last specification:

- Either the `'ENABLED'`, `'DISABLED'`, or `'FORCED'` keyword that follows the `STAR_JOIN` directive,
- or the comma-separated list of one or more *table* identifiers that specifies the setting of an optimizer environment attribute.
- If the setting is the empty string or the `DEFAULT` keyword, the `FACT`, `AVOID_FACT`, or `NON_DIM` optimizer directive that follows the `ENVIRONMENT` keyword does not affect the query optimizer during subsequent queries in the same session. You can use this option to disable a previously specified `FACT`, `AVOID_FACT`, or `NON_DIM` optimizer directive.

The following restrictions apply to blank spaces within the `SET OPTIMIZATION ENVIRONMENT` statement:

- If a comma-separated list of more than one *table* identifier follows the `FACT`, `AVOID_FACT`, or `NON_DIM` keywords, do not include blank spaces between any of the items in the list.
- Similarly, do not include blank characters between the two single ( `'` ) or two double ( `"` ) delimiters of the empty string that is a synonym for the `DEFAULT` keyword.

For example, the following statements override any previous directives to prevent the query optimizer from considering any specific tables as fact tables or as dimension tables:

```
SET OPTIMIZATION ENVIRONMENT AVOID_FACT '';
SET OPTIMIZATION ENVIRONMENT NON_DIM '';
```

By associating the `AVOID_FACT`, or `NON_DIM` keywords with an empty set of tables, the statements in the examples above allow any table to be considered as a fact table or as a dimension table in a star-join execution path.

### Configuring optimization at connection time

The DBA can use an `sysdbopen()` routine to define an optimization environment that takes effect when the user connects to the database. For example, to specify an optimizer environment that always favors a star-join execution plan, the `sysdbopen()` routine should include these SQL statements:

```
SET OPTIMIZATION ENVIRONMENT STAR_JOIN 'FORCED';
SET OPTIMIZATION ENVIRONMENT FACT 'table1,table2, ... tableN';
```

In the `SET OPTIMIZATION ENVIRONMENT FACT` statement, the tables listed after the `FACT` keyword should all be fact tables.

### Additional methods for enabling join directives

The `SET OPTIMIZATION ENVIRONMENT` statement is one of several ways to specify `FACT` optimizer directives:

- Directives within the `SELECT` statement, embedded comment-like. The scope is the SQL statement.
- The `SET OPTIMIZATION ENVIRONMENT FACT` statement. The scope is the session.
- The `SAVE EXTERNAL DIRECTIVES` statement. The scope is the database. This can define `FACT` directives and save them in the `sysdirectives` system catalog table.

Three mechanisms exist for enabling the query optimizer to consider external directives in the `sysdirectives` system catalog table, including any `FACT` directives. This is the (approximately) ascending order of precedence:

- The `EXT_DIRECTIVES` configuration parameter. If this is set to `2`, external directives are enabled for the database server, unless the `IFX_EXTDIRECTIVES` environment variable on the client system is set to `0`.
- The `IFX_EXTDIRECTIVES` environment variable. If this is set to `1` on the client system, external optimizer directives are enabled for the database server, unless the `EXT_DIRECTIVES` configuration parameter is set to `0`.
- The `SET ENVIRONMENT` statement. To enable the query optimizer to consider the external optimizer directives in `sysdirectives` when it chooses an execution path for queries during the current session, the DBA can issue any of these statements:

```
SET ENVIRONMENT EXTDIRECTIVES on;
SET ENVIRONMENT EXTDIRECTIVES ON;
SET ENVIRONMENT EXTDIRECTIVES '1';
SET ENVIRONMENT EXTDIRECTIVES "1";
```

To prevent the query optimizer from considering external optimizer directives in `sysdirectives`, the DBA can issue any of these statements:

```
SET ENVIRONMENT EXTDIRECTIVES off;
SET ENVIRONMENT EXTDIRECTIVES OFF;
SET ENVIRONMENT EXTDIRECTIVES '0';
SET ENVIRONMENT EXTDIRECTIVES "0";
```

These statements override (for the current session only) any conflicting settings of the `EXT_DIRECTIVES` configuration parameter or of the `IFX_EXTDIRECTIVES` environment variable.

For information about the SET ENVIRONMENT EXTDIRECTIVES statement, see [EXTDIRECTIVES session environment option on page 919](#).

For a table showing the effects of various combinations of **EXT\_DIRECTIVES** settings and **IFX\_EXTDIRECTIVES** settings on enabling or disabling external optimizer directives, see [Enabling or disabling external directives for a session on page 763](#).

For information about query optimizer directives that can favor or avoid star-join execution plans, see [Star-Join Directives on page 1483](#).

For information about how to use the built-in **sysdbopen()** routine to define the session environment at the time of connection for a specified user, for the PUBLIC group, or for a role, see Session Configuration Procedures.

## SET PDQPRIORITY statement

The SET PDQPRIORITY statement enables an application to set the query priority level dynamically within a routine. The SET PDQPRIORITY statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

**SET PDQPRIORITY**

**DEFAULT LOW**

**OFF**

**HIGH** *resources*

| Element          | Description   | Restrictions  | Syntax                                      |
|------------------|---|---|---|
| <i>resources</i> | Integer that specifies the query priority level and the percent of resources to process the query | Can range from -1 to 100. See also <a href="#">Allocating Database Server Resources on page 994</a> . | <a href="#">Literal Number on page 1419</a> |

### Usage

The SET PDQPRIORITY statement overrides the PDQPRIORITY environment variable (but has lower precedence than the **MAX\_PDQPRIORITY** configuration parameter). The scope of SET PDQPRIORITY is local to the routine, and does not affect other routines within the same session. When a routine that issues this statement terminates, the setting reverts to the system default value.

Set PDQ priority to a value less than the quotient of 100 divided by the maximum number of prepared statements. For example, if two prepared statements are active, you should set the PDQ priority to less than 50.

For example, assume that the DBA sets the **MAX\_PDQPRIORITY** parameter to 50. Then a user enters the following SET PDQPRIORITY statement to set the query priority level to 80 percent of resources:

```
SET PDQPRIORITY 80;
```

When it processes the query, the database server uses the **MAX\_PDQPRIORITY** value to factor the query priority level set by the user. The database server silently processes the query with a priority level of 40. This priority level represents 50 percent of the 80 percent of resources that the user specifies.

The following keywords are supported by the SET PDQPRIORITY statement.

**Keyword**

**Effect**

**DEFAULT**

Uses the setting of the **PDQPRIORITY** environment variable

**LOW**

Data values are fetched from fragmented tables in parallel. (In Informix®, when you specify LOW, the database server uses no other forms of parallelism.)

**OFF**

PDQ is turned off (Informix® only). The database server uses no parallelism. OFF is the default if you use neither the PDQPRIORITY environment variable nor the SET PDQPRIORITY statement.

**HIGH**

The database server determines an appropriate PDQPRIORITY value, based on factors that include the number of available processors, the fragmentation of the tables being queried, the complexity of the query, and others. reserves the right to change the performance behavior of queries when HIGH is specified in future releases.

The following SET PDQPRIORITY statements have the same effects:

```
SET PDQPRIORITY DEFAULT;
SET PDQPRIORITY -1;
```

Both replace any prior SET PDQPRIORITY level with the setting of the PDQPRIORITY environment variable. See also, however, the following description of the order of precedence among methods for allocating query priority resources.

### Precedence of methods for allocating PDQ priority

For memory available in operations that are affected by PDQPRIORITY, the maximum amount of memory that the database server can allocate is limited by the physical memory available to your system, and by the settings (in ascending order of lowest precedence to highest precedence) of the following environment variables, SQL statements, configuration parameters, and session environment variables:

- The PDQPRIORITY environment variable
- The most recent SET PDQPRIORITY statement of SQL
- The **MAX\_PDQPRIORITY** configuration parameter
- The **DS\_TOTAL\_MEMORY** configuration parameter
- The BOUND\_IMPL\_PDQ session environment variable, if the IMPLICIT\_PDQ session environment variable is enabled in the current session by the SET ENVIRONMENT statement of SQL.

The scope of the SET ENVIRONMENT BOUND\_IMPL\_PDQ and SET ENVIRONMENT IMPLICIT\_PDQ statements is the current session.

When concurrent queries are running, the **DS\_MAX\_QUERIES** configuration parameter setting can also restrict the amount of PDQ memory available for a new query.

---

**Related reference**[SET ENVIRONMENT statement on page 900](#)

## Allocating Database Server Resources

You can specify an integer in the range from `-1` to `100` to indicate a query priority level as the percent of database server resources to process the query. Resources include the amount of memory and the number of processors. The higher the number you specify, the more resources the database server uses.

Use of more resources usually indicates better performance for a given query. Using excessive resources, however, can cause contention for resources and remove resources from other queries, so that degraded performance results. With the *resources* option, the following values are numeric equivalents of the keywords that indicate query priority level.

**Value****Equivalent Keyword-Priority Level**`-1`

DEFAULT

`0`

OFF

`1`

LOW

For Informix®, the following statements are equivalent. The first statement uses the keyword `LOW` to establish a low query-priority level. The second uses a value of `1` in the *resources* parameter to establish a low query-priority level.

```
SET PDQPRIORITY LOW;
```

```
SET PDQPRIORITY 1;
```

## SET ROLE statement

Use the `SET ROLE` statement to enable the privileges of a user-defined role. This statement is an extension to the ANSI/ISO standard for SQL.

**Syntax****SET ROLE***role* 'role'**NULL NONE DEFAULT**

| Element     | Description                  | Restrictions  | Syntax                                    |
|-------------|------------------------------|---|---|
| <i>role</i> | Name of a role to be enabled | Must already exist in the database and must already have been granted to the user, but cannot be a built-in role. If enclosed between quotation marks, <i>role</i> is case sensitive. | <a href="#">Owner name on page 1488</a> ; |

## Usage

Any user who is granted a role can enable the role by using the SET ROLE statement. You can only enable one role at a time. If you execute the SET ROLE statement after a role is already set, the new role replaces the old role as the current role.

The SET ROLE statement returns an error if the user does not currently hold the role, or if the role is a built-in role. (The access privileges held by a built-in role, such as the EXTEND role or the DBSECADM role, are always in effect, and do not require activation by the SET ROLE statement if the user holds that role.)

Users can be granted a default role for the database instance when the DBA issues the GRANT DEFAULT ROLE statement. If no default role exists for the user in the current database, role NULL or NONE is assigned by default. In this context, NULL and NONE are synonyms. Roles NULL and NONE can have no privileges. To set your role to NULL or NONE disables your current role.

When you use SET ROLE to enable a role, you gain the privileges of the role, in addition to the privileges of PUBLIC and your own privileges. If a role is granted to another role that has been assigned to you, you gain the privileges of both roles, in addition to any privileges of PUBLIC and your own privileges.

After SET ROLE executes successfully, the specified role remains effective until the current database is closed or the user executes another SET ROLE statement. Only the user, however, not the role, retains ownership of any database objects, such as tables, that were created during the session.

A role is in scope only within the current database. You cannot use privileges that you acquire from a role to access data in another database. For example, if you have privileges from a role in the database named **acctg**, and you execute a distributed query over the databases named **acctg** and **inventory**, your query cannot access the data in the **inventory** database unless you were also granted appropriate privileges in the **inventory** database. As a security precaution, discretionary access privileges that the user holds only from a role cannot provide access to tables outside the current database through a view or through the action of a trigger.

If your database supports explicit transactions, you must issue the SET ROLE statement outside a transaction. If your database is ANSI-compliant, SET ROLE must be the first statement of a new transaction. If the SET ROLE statement is executed while a transaction is active, an error occurs. For more information about SQL statements that initiate an implicit transaction, see [SET SESSION AUTHORIZATION and Transactions on page 999](#).

If the SET ROLE statement is executed as a part of a trigger or SPL routine, and the owner of the trigger or SPL routine was granted the role with the WITH GRANT OPTION, the role is enabled even if you are not granted the role. For example, this code fragment sets a role and then relinquishes it after a query:

```
EXEC SQL set role engineer;
EXEC SQL select fname, lname, project
        INTO :efname, :elname, :eproject FROM projects
        WHERE project_num > 100 AND lname = 'Larkin';
printf ("%s is working on %s\n", efname, eproject);
EXEC SQL set role NULL;
```

---

**Related reference**[CREATE ROLE statement on page 303](#)[DROP ROLE statement on page 521](#)[GRANT statement on page 592](#)[REVOKE statement on page 727](#)

## Setting the Default Role

The DBA or the owner of the database can issue the GRANT DEFAULT ROLE statement to assign an existing role as the *default role* to a specified list of users or to PUBLIC. Unlike a non-default role, the default role does not require the SET ROLE statement to enable it. When a user is assigned to the default role, an implicit connection to the database is granted to the user.

Each of the three statements in next example respectively performs one of the following operations on a role:

- Declares a role called **Engineer**
- Assigns Select privileges on the **locomotives** table to the **Engineer** role
- Defines **Engineer** as the default role for the user **jgould**.

```
EXEC SQL CREATE ROLE 'Engineer';
EXEC SQL GRANT SELECT ON locomotives TO 'Engineer';
EXEC SQL GRANT DEFAULT ROLE 'Engineer' TO jgould;
```

If **jgould** subsequently uses the SET ROLE statement to enable some other role, then by executing the following statement, **jgould** replaces that role with **Engineer** as the current role:

```
SET ROLE DEFAULT;
```

If you have no default role, SET ROLE DEFAULT makes NONE your current role, leaving only the privileges that have been granted explicitly to your *username* or to PUBLIC. After GRANT DEFAULT ROLE changes your default role to a new default role, executing SET ROLE DEFAULT restores your most recently granted default role, even if this role was not your default role when you connected to the database.

If one default role is granted to PUBLIC, but a different role is granted as the default role to an individual user, the individually-granted default role takes precedence if that user issues SET ROLE DEFAULT or connects to the database.

## SET SESSION AUTHORIZATION statement

The SET SESSION AUTHORIZATION statement lets you change the user name under which database operations are performed in the current session.

**Syntax****SET SESSION AUTHORIZATION TO***'user\_identifier' user\_ID\_variable***USING***password auth\_variable*

| Element                 | Description   | Restrictions   | Syntax  |
|-------------------------|---|--|---|
| <i>auth_variable</i>    | Host variable that holds the valid password for the login name specified in <i>user_identifier</i> or <i>user_ID_variable</i> . | Variable must be a fixed-length character data type. Its value has the same restrictions as <i>password</i> .        | Must conform to language-specific rules for variable names. |
| <i>password</i>         | Quoted string that is the password of the specified user.   | Must be the password of that user, and no more than 32 bytes   | <a href="#">Quoted String on page 1424</a>                  |
| <i>user_identifier</i>  | Quoted string that is a valid login name for the application. The quotation mark delimiters preserve the lettercase.            | Authorization identifier of no more than 32 bytes  | <a href="#">Quoted String on page 1424</a>                  |
| <i>user_ID_variable</i> | The name of an ESQL/C host variable that holds the value of a user identifier.  | Variable must be a fixed-length character data type. Its value has the same restrictions as <i>user_identifier</i> . | Must conform to language-specific rules for variable names. |

**Usage**

This statement allows you to assume the identity of another user, including the discretionary access control (DAC) and label-based access control (LBAC) credentials. You can also use this statement in an API that supports Informix® trusted contexts to switch the user ID on a trusted connection.

Both the DBA and SETSESSIONAUTH access privilege are required to execute this statement. Unless when you start the session you already hold the SETSESSIONAUTH privilege for PUBLIC (or for the user whose name you specify in the SET SESSION AUTHORIZATION statement), and you also hold the DBA privilege, this statement fails with an error.

If the database server has been converted from a legacy version that did not support label-based access control, users who held the DBA privilege are automatically granted the SETSESSIONAUTH access privilege for PUBLIC in the migration process. If the database server has been initialized as a version that supports LBAC security policies, users who hold the **DBSECADM** role can grant the SETSESSIONAUTH privilege to other users. Because the security credentials of each user determine what data rows can be accessed in protected tables, the **DBSECADM** should exercise care in granting the SETSESSIONAUTH privilege and in specifying its scope.

The new identity remains in effect in the current database until you execute SET SESSION AUTHORIZATION again, or until you close the current database. When you use this statement, the specified *user* must have the Connect privilege on the

current database. In addition, the DBA cannot set the new authorization identifier to the PUBLIC group, nor to any existing role in the current database.

Setting a session to another user causes a change in a user name in the current active database server. The specified *user*, as far as this database server process is concerned, is completely dispossessed of any privileges while accessing the database server through some administrative utility. Additionally, the new session *user* is not able to initiate any administrative operation (execute a utility, for example) by virtue of the acquired identity.

After the SET SESSION AUTHORIZATION statement successfully executes, any role enabled by a previous user is relinquished. You must use the SET ROLE statement if you wish to assume a role that has been granted to the specified *user*. The database server does not enable the default role of *user* automatically.

After SET SESSION AUTHORIZATION successfully executes, the database server puts any owner-privileged UDRs that the DBA created while using the new authorization identifier in RESTRICTED mode, which can affect access privileges during operations of the UDR on objects in remote databases. For more information on RESTRICTED mode, see the **sysprocedures** system catalog table in the *Informix® Guide to SQL: Reference*.

When you assume the identity of another user by executing the SET SESSION AUTHORIZATION statement, you can perform operations in the current database only. You cannot perform an operation on a database object outside the current database, such as a remote table. In addition, you cannot execute a DROP DATABASE or RENAME DATABASE statement, even if the database is owned by the real user or by the effective user.

You can use this statement either to obtain access to the data directly or to grant the database-level or table-level privileges needed for the database operation to proceed. The following example shows how to use the SET SESSION AUTHORIZATION statement to obtain table-level privileges:

```
SET SESSION AUTHORIZATION TO 'cathl';
GRANT ALL ON customer TO 'mary';
SET SESSION AUTHORIZATION TO 'mary';
UPDATE customer SET fname = 'Carl' WHERE lname = 'Pauli';
```

If you enclose *user* in quotation marks, the name is case sensitive and is stored exactly as you typed it. In an ANSI-compliant database, if you do not use quotation marks as delimiters, the authorization identifier is stored in uppercase letters, unless the **ANSIOWNER** environment variable is set to prevent the conversion of lowercase letters to uppercase.

The following Open Database Connectivity (ODBC) API example enables user ID switching on a trusted connection with an authentication requirement:

```
SQLExecDirect(hstmt, "SET SESSION AUTHORIZATION TO 'zurbie' USING 'pass01'", SQL_NTS);
```

In the function call above,

- `'zurbie'` specifies the authorization identifier for subsequent operations in this session
- `pass01` must be the current password of user **zurbie**.

**Note:**

Except in a non-hostile environment, 'pass01' is not a recommended example of a login password, because in some locales it might be easy to guess.

## SET SESSION AUTHORIZATION and Transactions

If your database is not ANSI compliant, you must issue the SET SESSION AUTHORIZATION statement outside a transaction. If you issue the statement within a transaction, you receive an error message.

In an ANSI-compliant database, you can execute the SET SESSION AUTHORIZATION statement only if you have not executed a statement that initiates an implicit transaction (for example, CREATE TABLE or SELECT). Statements that do not initiate an implicit transaction are statements that do not acquire locks or log data (for example, SET EXPLAIN and SET ISOLATION). You can execute the SET SESSION AUTHORIZATION statement immediately after a DATABASE statement or a COMMIT WORK statement.

## SET STATEMENT CACHE statement

Use the SET STATEMENT CACHE statement to turn on caching or turn off caching for the current session. This statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

**SET STATEMENT CACHE**

**ON OFF**

### Usage

You can use the SET STATEMENT CACHE statement to turn caching in the SQL statement cache ON or OFF for the current session. The statement cache stores in a buffer identical statements that are repeatedly run in a session. Only data manipulation language (DML) statements (DELETE, INSERT, UPDATE, or SELECT) can be stored in the statement cache.

This mechanism allows qualifying statements to bypass the optimization stage, and avoid recompiling, which can reduce memory consumption and can improve query processing time.

## Examples

The following example turns on statement caching for the current session:

```
SET STATEMENT CACHE ON;
```

The following turns off statement caching for the current session:

```
SET STATEMENT CACHE OFF;
```

---

### Related reference

[SAVE EXTERNAL DIRECTIVES statement on page 762](#)

[SET OPTIMIZATION statement on page 985](#)

[Optimizer Directives on page 1472](#)

## Precedence and Default Behavior

SET STATEMENT CACHE takes precedence over the **STMT\_CACHE** environment variable and the STMT\_CACHE configuration parameter. You must enable the SQL statement cache, however, either by setting the STMT\_CACHE configuration parameter or by using the **onmode** utility, before the SET STATEMENT CACHE statement can execute successfully.

When you issue a SET STATEMENT CACHE ON statement, the SQL statement cache remains in effect until you issue a SET STATEMENT CACHE OFF statement or until the program ends. If you do not use SET STATEMENT CACHE, the default behavior depends on the setting of the **STMT\_CACHE** environment variable or the STMT\_CACHE configuration parameter.

## Turning the Cache ON

Use the ON option to enable the SQL statement cache. When the SQL statement cache is enabled, each statement that you execute passes through the SQL statement cache to determine if a matching cache entry is present. If so, the database server uses the cached entry to execute the statement.

If the statement has no matching entry, the database server tests to see if it qualifies for entry into the cache. For the conditions a statement must meet to enter into the cache, see [SQL statement cache qualifying criteria on page 1001](#).

## Restrictions on Matching Entries in the SQL Statement Cache

When the database server considers whether or not a statement is identical to a statement in the SQL statement cache, the following items must match:

- Lettercase
- Comments
- White space
- Optimization settings

- SET OPTIMIZATION statement options
- Optimizer directives
- The SET ENVIRONMENT OPTCOMPIND statement options or settings of the **OPTCOMPIND** environment variable, or of the OPTCOMPIND configuration parameter in the ONCONFIG file. (If conflicting settings exist for the same query, this is the descending order of precedence.)
- Parallelism settings
  - SET PDQPRIORITY statement options or settings of the **PDQPRIORITY** environment variable
- Query text strings
- Literals

If an SQL statement is semantically equivalent to a statement in the SQL statement cache but has different literals, the statement is not considered identical and qualifies for entry into the cache. For example, the following SELECT statements are not identical:

```
SELECT col1, col2 FROM tab1 WHERE col1=3;
SELECT col1, col2 FROM tab1 WHERE col1=5;
```

In this example, both statements are entered into the SQL statement cache.

Host-variable names, however, are insignificant. For example, the following select statements are considered identical:

```
SELECT * FROM tab1 WHERE x = :x AND y = :y;
SELECT * FROM tab1 WHERE x = :p AND y = :q;
```

In the previous example, although the host names are different, the statements qualify, because the case, query text strings, and white space match. Performance does not improve, however, because each statement has already been parsed and optimized by the PREPARE statement.

## Turning the Cache OFF

The OFF option disables the SQL statement cache. When you turn caching OFF for your session, no SQL statement cache code is executed for that session.

The SQL statement cache is designed to save memory in environments where identical queries are executed repeatedly and schema changes are infrequent. If this is not the case, you might want to turn the SQL statement cache off to avoid the overhead of caching. For example, if you have little cache cohesion, that is, when relatively few matches but many new entries into the cache exist, the cache management overhead is high. In this case, turn the SQL statement cache off.

If you know that you are executing many statements that do not qualify for the SQL statement cache, you might want to disable it and avoid the overhead of testing to see if each DML statement qualifies for insertion into the cache.

## SQL statement cache qualifying criteria

A statement that can be cached in the SQL statement cache (and consequently, one that can match a statement that already appears in the SQL statement cache) must meet specified conditions.

To qualify for caching, the statement must meet all of the following conditions:

- It must be a SELECT, INSERT, UPDATE, or DELETE statement.
- It must contain only non-opaque built-in data types (excluding BLOB, BOOLEAN, BYTE, CLOB, LVARCHAR, and TEXT).
- It must contain only built-in operators.
- It cannot contain user-defined routines.
- It cannot contain temporary or remote tables.
- It cannot contain subqueries in the Projection list.
- It cannot be part of a multistatement PREPARE.
- It cannot have user-privilege restrictions on target columns.
- In an ANSI-compliant database, it must contain fully qualified object names.
- It cannot require re-optimization.

## Requiring Re-Execution Before Cache Insertion

A qualified SQL statement is fully inserted into the SQL statement cache only after the database server counts a configurable number of references (which are sometimes called "hits") to that statement. For the default value of zero, a qualified DML statement does not need to be re-executed before it is cached.

Using the `STMT_CACHE_HITS` configuration parameter, however, the database administrator (DBA) can specify that qualified DML statements must be executed a minimum number of times before they are inserted into the statement cache. By setting this to a value of one (or to a larger value), the DBA excludes one-time-only *ad hoc* queries from full insertion into the SQL statement cache, thereby lowering cache-management overhead.

## Enabling or Disabling Insertions After Size Exceeds Configured Limit

The DBA can prevent the insertion of additional qualified SQL statements into the statement cache when the cache size reaches its configured size (as specified by the `STMT_CACHE_SIZE` configuration parameter) by setting the configuration parameter `STMT_CACHE_NOLIMIT` to zero.

## Prepared Statements and the Statement Cache

Prepared statements are inherently cached for a single session. That is, if a prepared statement is executed many times (or if a single cursor is opened many times), the same prepared query plan is used repeatedly by that session.

If a session prepares a statement and then executes it many times, its performance is essentially unaffected by using the SQL statement cache, because the statement is optimized just once, during the PREPARE statement.

If other sessions also prepare that same statement, however, or if the first session prepares the statement several times, then the statement cache usually provides a direct performance benefit, because the database server only calculates the query plan once. Of course, the original session might gain a small benefit from the statement cache, even if it prepares

the statement only once, because other sessions use less memory, and the database server does less work for the other sessions.

## SET TRANSACTION statement

Use the SET TRANSACTION statement to define the isolation level and to specify whether the access mode of a transaction is read-only or read-write.

### Syntax

#### SET TRANSACTION

,  
458

#### READ WRITE READ ONLY

<sup>458</sup> ISOLATION LEVEL

#### READ COMMITTED REPEATABLE READ SERIALIZABLE READ UNCOMMITTED

### Usage

SET TRANSACTION is valid only in databases with transaction logging. You can issue this statement from a client computer only after a database is opened. The transaction isolation level affects concurrency among processes that attempt to access the same rows simultaneously from the database. The database server uses shared locks to support different levels of isolation among processes that are attempting to read data, as the following list shows:

- Read Uncommitted
- Read Committed
- (ANSI) Repeatable Read
- Serializable

The update or delete process always acquires an exclusive lock on the row that is being modified. The level of isolation does not interfere with such rows, but the access mode does affect whether you can update or delete rows.

If another process attempts to update or delete rows that you are reading with an isolation level of Serializable or (ANSI) Repeatable Read, that process will be denied access to those rows.

---

#### Related reference

[SET LOCK MODE statement on page 982](#)

[CREATE DATABASE statement on page 201](#)

[SET ISOLATION statement on page 974](#)

458. Use path no more than once

## Comparing SET TRANSACTION with SET ISOLATION

The SET TRANSACTION statement complies with ANSI SQL-92. This statement is similar to the Informix® SET ISOLATION statement; however, the SET ISOLATION statement is not ANSI compliant and does not provide access modes. In fact, the isolation levels that you can set with the SET TRANSACTION statement are almost parallel to the isolation levels that you can set with the SET ISOLATION statement, as the following table shows.

| SET TRANSACTION Isolation Level | SET ISOLATION Isolation Level |
|---------------------------------|-------------------------------|
| Read Uncommitted                | Dirty Read                    |
| Read Committed                  | Committed Read                |
| [ <i>Not supported</i> ]        | Cursor Stability              |
| (ANSI) Repeatable Read          | (Informix®) Repeatable Read   |
| Serializable                    | (Informix®) Repeatable Read   |

Another difference between SET TRANSACTION and SET ISOLATION is the behavior of the isolation levels within transactions. You can issue SET TRANSACTION only once for a transaction. Any cursors that are opened during that transaction are guaranteed that isolation level (or access mode, if you are defining an access mode). With SET ISOLATION, after a transaction is started, you can change the isolation level more than once within the transaction.

The following examples illustrate this difference in the behavior of the SET ISOLATION and SET TRANSACTION statements:

```
EXEC SQL BEGIN WORK;
EXEC SQL SET ISOLATION TO DIRTY READ;
EXEC SQL SELECT ... ;
EXEC SQL SET ISOLATION TO REPEATABLE READ;
EXEC SQL INSERT ... ;
EXEC SQL COMMIT WORK;    -- Executes without error
```

Compare the previous example to these SET TRANSACTION statements:

```
EXEC SQL BEGIN WORK;
EXEC SQL SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
EXEC SQL SELECT ... ;
EXEC SQL SET TRANSACTION ISOLATION LEVEL READ COMMITTED;
-- Produces error 876: Cannot issue SET TRANSACTION
-- in an active transaction.
```

An additional difference between SET ISOLATION and SET TRANSACTION is the duration of isolation levels. Because SET ISOLATION supports complete-connection level settings, the isolation level specified by SET ISOLATION remains in effect until another SET ISOLATION statement is issued. The isolation level set by SET TRANSACTION only remains in effect until the transaction terminates. Then the isolation level is reset to the default for the database type.

## Informix® Isolation Levels

The following definitions explain the critical characteristics of each isolation level, from the lowest level of isolation to the highest.

## Using the Read Uncommitted Option

Use the Read Uncommitted option to copy rows from the database whether or not locks are present on them. The program that fetches a row places no locks and it respects none. Read Uncommitted is the only isolation level available to databases that do not have transactions.

This isolation level is most appropriate in queries of static tables whose data is not being modified, because it provides no isolation. With Read Uncommitted, the program might return an uncommitted row that was inserted or modified within a transaction that was subsequently rolled back.

The Uncommitted Read isolation level of SET TRANSACTION does not directly support the LAST COMMITTED feature of the Committed Read isolation level of the SET ISOLATION statement. The LAST COMMITTED feature can reduce the risk of locking conflicts when an application attempts to read a row on which another session holds an exclusive lock while modifying data. When this feature is enabled, the database server returns the most recently committed version of the data, rather than wait for the lock to be released.

This feature takes effect implicitly, however, in all user sessions that use the Read Uncommitted isolation level of the SET TRANSACTION statement, under either of the following circumstances:

- if the USELASTCOMMITTED configuration parameter is set to `'DIRTY READ'` or to `'ALL'`
- if the SET ENVIRONMENT statement set the USELASTCOMMITTED session environment option to `'DIRTY READ'` or to `'ALL'`.

See the section [The LAST COMMITTED Option to Committed Read on page 977](#) for more information about the LAST COMMITTED feature and its restrictions.

## Using the Read Committed Option

Use the Read Committed option to guarantee that every retrieved row is committed in the table at the time that the row is retrieved. This option does not place a lock on the fetched row. Read Committed is the default level of isolation in a database with logging that is not ANSI compliant.

Read Committed is appropriate when each row of data is processed as an independent unit, without reference to other rows in the same or other tables.

The Read Committed isolation level of SET TRANSACTION does not directly support the LAST COMMITTED feature of the Committed Read isolation level of the SET ISOLATION statement, which can reduce the risk of locking conflicts when an application attempts to read data in a row on which another session holds an exclusive row-level lock. When this feature is enabled, the database server returns the most recently committed version of the data, rather than wait for the lock to be released

This feature takes effect implicitly, however, in all user sessions that use the Read Committed isolation level of the SET TRANSACTION statement, under either of the following circumstances:

- if the USELASTCOMMITTED configuration parameter is set to 'COMMITTED READ' or to 'ALL'
- if the SET ENVIRONMENT statement set the USELASTCOMMITTED session environment variable to 'COMMITTED READ' or to 'ALL'.

See the section [The LAST COMMITTED Option to Committed Read on page 977](#) for more information about the LAST COMMITTED feature and its restrictions.

## Using the Repeatable Read and Serializable Options

The Informix® implementation of Repeatable Read and of Serializable are equivalent. The Serializable (or Repeatable Read) option places a shared lock on every row that is selected during the transaction.

Another process can also place a shared lock on a selected row, but no other process can modify any selected row during your transaction or insert a row that meets the search criteria of your query during your transaction.

A *phantom row* is a row that was not visible when you first read the query set, but that materializes in a subsequent read of the query set in the same transaction. Only this isolation level prevents access to a phantom row.

If you repeat the query during the transaction, you reread the same data. The shared locks are released only when the transaction is committed or rolled back. Serializable is the default isolation level in an ANSI-compliant database. Serializable isolation places the largest number of locks and holds them the longest. Therefore, it is the level that reduces concurrency the most.

## Default Isolation Levels

The default isolation level is established when you create the database.

| Informix® Name  | ANSI Name        | When This Is the Default Level of Isolation        |
|-----------------|------------------|--|
| Dirty Read      | Read Uncommitted | Database without transaction logging               |
| Committed Read  | Read Committed   | Databases with logging that are not ANSI-compliant |
| Repeatable Read | Serializable     | ANSI-compliant databases                           |

For Informix® databases that are not ANSI-compliant, unless you explicitly set the USELASTCOMMITTED configuration parameter, the LAST COMMITTED feature is not in effect for the default isolation levels. The SET ENVIRONMENT statement or the SET ISOLATION statement can override this default and enable LAST COMMITTED for the current session.

The default isolation level remains in effect until you issue a SET TRANSACTION statement within a transaction. After a COMMIT WORK statement completes the transaction or a ROLLBACK WORK statement cancels the entire transaction, the isolation level is reset to the default.

When you use High Availability Data Replication, the database server effectively uses Dirty Read isolation on the HDR Secondary Server, regardless of the specified **SET ISOLATION** or **SET TRANSACTION** isolation level, unless the UPDATABLE\_SECONDARY configuration parameter is enabled. For more information about this topic, see [Isolation Levels for Secondary Data Replication Servers on page 982](#).

## Access Modes

Access modes affect read and write concurrency for rows within transactions. Use access modes to control data modification. `SET TRANSACTION` can specify that a transaction is read-only or read-write. By default, transactions are read-write. When you specify a read-only transaction, certain limitations apply. Read-only transactions cannot perform the following actions:

- Insert, delete, or update rows of a table.
- Create, alter, or drop any database object such as schemas, tables, temporary tables, indexes, or SPL routines.
- Grant or revoke access privileges.
- Update statistics.
- Rename columns or tables.

You can execute SPL routines in a read-only transaction as long as the SPL routine does not try to perform any restricted statement.

## Effects of Isolation Levels

You cannot set the transaction isolation level in a database that does not have logging. Every retrieval in an unlogged database occurs as a Read Uncommitted.

The data that is obtained during retrieval of BYTE or TEXT data can vary, depending on the transaction isolation levels. Under Read Uncommitted or Read Committed isolation levels, a process is permitted to read a BYTE or TEXT column that is either deleted (if the delete is not yet committed) or in the process of being deleted. Under these isolation levels, an application can read a deleted BYTE or TEXT column when certain conditions exist. For information about these conditions, see the *Informix® Administrator's Guide*.

In Informix® ESQL/C, if you use a scroll cursor in a transaction, you can force consistency between your temporary table and the database table either by setting the isolation level to Serializable or by locking the entire table. A scroll cursor with hold, however, cannot guarantee the same consistency between the two tables. Table-level locks set by Serializable are released when the transaction is completed, but the scroll cursor with hold remains open beyond the end of the transaction. You can modify released rows as soon as the transaction ends, so the retrieved data in the temporary table might be inconsistent with the actual data.

**Warning:** Do not use nonlogging tables within a transaction. If you need to use a nonlogging table within a transaction, either set the isolation level to Repeatable Read or lock the table in exclusive mode to prevent concurrency problems.

## SET Transaction Mode statement

Use the SET Transaction Mode statement to specify whether constraints are checked at the statement level or at the transaction level during the current transaction.

### Syntax

#### SET CONSTRAINTS

, *constraint*

#### ALL

#### IMMEDIATE DEFERRED

| Element           | Description  | Restrictions  | Syntax                                  |
|-------------------|--|---|---|
| <i>constraint</i> | Constraint whose transaction mode is to be changed | All constraints must exist in the same database, which must support logging | <a href="#">Identifier on page 1456</a> |

### Usage

To enable or disable constraints, or to change their filtering mode, see [SET Database Object Mode statement on page 871](#).

This statement is valid only in a database with transaction logging, and its effect is limited to the transaction in which it is executed.

Use the IMMEDIATE keyword to set the transaction mode of constraints to statement-level checking. IMMEDIATE is the default transaction mode of constraints when they are created.

Use the DEFERRED keyword to set the transaction mode to transaction-level checking. You cannot change the transaction mode of a constraint to DEFERRED unless the constraint is currently enabled.

#### Related reference

[CREATE TABLE statement on page 335](#)

[ALTER TABLE statement on page 99](#)

[SET CONSTRAINTS statement on page 869](#)

## Statement-Level Checking

When you set the transaction mode to IMMEDIATE, statement-level checking is turned on, and all specified constraints are checked at the end of each INSERT, UPDATE, or DELETE statement. If a constraint violation occurs, the statement is not executed.

## Transaction-Level Checking

When you set the transaction mode of constraints to DEFERRED, statement-level checking is turned off, and all (or the specified) constraints are not checked until the transaction is committed. If a constraint violation occurs while the transaction is being committed, the transaction is rolled back.

**Tip:** If you defer checking a primary-key constraint, checking the not-NULL constraint for that column or set of columns is also deferred.

## Duration of Transaction Modes

The duration of the transaction mode that the SET Transaction Mode statement specifies is the transaction in which the SET Transaction Mode statement is executed. You cannot execute this statement outside a transaction. Once a COMMIT WORK or ROLLBACK WORK statement is successfully completed, the transaction mode of all constraints reverts to IMMEDIATE.

To switch from transaction-level checking to statement-level checking, you can use the SET Transaction Mode statement to set the transaction mode to IMMEDIATE, or you can use a COMMIT WORK or ROLLBACK WORK statement to terminate your transaction.

## Specifying All Constraints or a List of Constraints

You can specify all constraints in the database in the SET Transaction Mode statement, or you can specify a single constraint, or list of constraints.

If you specify the ALL keyword, the SET Transaction Mode statement sets the transaction mode for all constraints in the database. If any statement in the transaction requires that any constraint on any table in the database be checked, the database server performs the checks at the statement level or the transaction level, depending on the setting that you specify in the SET Transaction Mode statement.

If you specify a single constraint name or a list of constraints, the SET Transaction Mode statement sets the transaction mode for the specified constraints only. If any statement in the transaction requires checking of a constraint that you did not specify in the SET Transaction Mode statement, that constraint is checked at the statement level regardless of the setting that you specified in the SET Transaction Mode statement for other constraints.

When you specify a list of constraints, the constraints do not need to be defined on the same table, but they must exist in the same database.

## Specifying Remote Constraints

You can set the transaction mode of local constraints or remote constraints. That is, the constraints that are specified in the SET Transaction Mode statement can be constraints that are defined on local tables or constraints that are defined on remote tables.

## Examples of Setting the Transaction Mode for Constraints

The following example shows how to defer checking constraints within a transaction until the transaction is complete. The SET Transaction Mode statement in the example specifies that any constraints on any tables in the database are not checked until the COMMIT WORK statement is encountered.

```
BEGIN WORK;
SET CONSTRAINTS ALL DEFERRED;
...
COMMIT WORK;
```

The following example specifies that a list of constraints is not checked until the transaction is complete:

```
BEGIN WORK;
SET CONSTRAINTS update_const, insert_const DEFERRED;
...
COMMIT WORK;
```

## SET TRIGGERS statement

Use the SET TRIGGERS statement to enable or disable all or some of the triggers on a table, or all or some of the INSTEAD OF triggers on a view.

### Syntax

#### SET TRIGGERS

, *trigger*

#### FOR

'owner' .

*table view*

#### ENABLED

#### DISABLED

| Element        | Description  | Restrictions               | Syntax                                  |
|----------------|--|----------------------------|---|
| <i>owner</i>   | The owner of <i>table</i> or <i>view</i>                         | Must own the table or view | <a href="#">Owner name on page 1488</a> |
| <i>table</i>   | Table whose triggers are all to be enabled or disabled           | Must exist                 | <a href="#">Identifier on page 1456</a> |
| <i>trigger</i> | Trigger to be enabled or disabled                                | Must exist                 | <a href="#">Identifier on page 1456</a> |
| <i>view</i>    | View whose INSTEAD OF triggers are all to be enabled or disabled | Must exist                 | <a href="#">Identifier on page 1456</a> |

### Usage

The SET TRIGGERS statement is a special case of the SET Database Object Mode statement. The SET Database Object Mode statement can also enable or disable an index or a constraint, or change the filtering mode of a unique index or of a constraint.

For the complete syntax and semantics of the SET TRIGGERS statement, see [SET Database Object Mode statement on page 871](#).

### Restrictions on secondary servers

In cluster environments, the SET TRIGGERS statement is not supported on updatable secondary servers. (More generally, session-level index, trigger, and constraint modes that the SET Database Object Mode statement specifies are not redirected for UPDATE operations on table objects in databases of secondary servers.)

## SET USER PASSWORD statement (UNIX™, Linux™)

Use the SET USER PASSWORD statement to change your password for database server access if you are an internally authenticated user. This statement is an extension to the ANSI/ISO standard for the SQL language.

### Syntax

#### SET USER PASSWORD OLD

*old\_password***NEW***new\_password*

| Element             | Description  | Restrictions                           | Syntax                                     |
|---------------------|--|--|--|
| <i>new_password</i> | New password for internal authentication of the user.      | Length must be between 6 and 32 bytes. | <a href="#">Quoted String on page 1424</a> |
| <i>old_password</i> | Existing password for internal authentication of the user. | Length must be between 6 and 32 bytes. | <a href="#">Quoted String on page 1424</a> |

### Usage

A DBSA cannot use this statement to change the password of another user. To change the passwords of other users, a DBSA can use the ALTER USER statement.

Execution of the SET USER PASSWORD statement can be audited with the PWUR audit code.

### Example

#### Example

The following statement changes the password from **joebar** to **joefoo**:

```
SET USER PASSWORD OLD 'joebar' NEW 'joefoo';
```

## START VIOLATIONS TABLE statement

Use the START VIOLATIONS TABLE statement to create a violations table and a diagnostics table for a specified target table. The START VIOLATIONS TABLE statement is an extension to the ANSI/ISO standard for SQL.

**Syntax****START VIOLATIONS TABLE FOR***'owner'* .*table***USING***violations,diagnostics***MAX ROWS***num\_rows*

| Element            | Description   | Restrictions   | Syntax                                      |
|--------------------|---|--|---|
| <i>diagnostics</i> | Declares the name of a diagnostics table to be associated with the target <i>table</i> . Default name is <b>table_dia</b> .           | Must be unique among names of tables, views, sequences, and synonyms             | <a href="#">Identifier on page 1456</a>     |
| <i>num_rows</i>    | Maximum number of rows that the database server can insert into <i>violations</i> when a single statement is executed on <i>table</i> | Must be an integer in range from 1 to the maximum value of the INTEGER data type | <a href="#">Literal Number on page 1419</a> |
| <i>owner</i>       | The owner of <i>table</i>   | Must own the table   | <a href="#">Owner name on page 1488</a>     |
| <i>table</i>       | Target table for which <i>violations</i> and <i>diagnostics</i> tables are to be created  | If USING clause is omitted, no more than 124 bytes                               | <a href="#">Identifier on page 1456</a>     |
| <i>violations</i>  | Violations table to be associated with <i>table</i> . Default name is <b>table_vio</b> .  | Same restrictions as <i>diagnostics</i>  | <a href="#">Identifier on page 1456</a>     |

**Usage**

The database server associates the *violations* table and the *diagnostics* table) with the target table that you specify after the FOR keyword by recording the relationship among the three tables in the **sysviolations** system catalog table.

A target table must satisfy these requirements:

- It cannot be a table in a database that is not the current database.
- It cannot be an object that the CREATE EXTERNAL TABLE statement defined.
- It cannot already be associated with a violations or diagnostics table.
- It cannot be a system catalog table.

The START VIOLATIONS TABLE statement creates the special violations table that holds nonconforming rows that fail to satisfy constraints and unique indexes during insert, update, and delete operations on target tables. This statement also creates the special diagnostics table that contains information about the integrity violations that each row causes in the violations table.

[Modes for constraints and unique indexes on page 876](#)

[STOP VIOLATIONS TABLE statement on page 1024](#)

[CREATE INDEX statement on page 253](#)

[CREATE TABLE statement on page 335](#)

[SET Database Object Mode statement on page 871](#)

## Relationship to the SET Database Object Mode statement

The START VIOLATIONS TABLE statement is closely related to the SET Database Object Mode statement. If you use SET Database Object Mode to set the constraints or unique indexes defined on a table to the FILTERING mode, without also using START VIOLATIONS TABLE, any rows that violate a constraint or unique-index requirement in data manipulation operations are not filtered out to a violations table. Instead you receive an error message that indicates that you must start a violations table for the target table.

Similarly, if you use the SET Database Object Mode statement to set a disabled constraint or disabled unique index to the ENABLED or FILTERING mode, but you do not use START VIOLATIONS TABLE for the table on which the database objects are defined, any rows that do not satisfy the constraint or unique-index requirement are not filtered out to a violations table.

In these cases, to identify the rows that do not satisfy the constraint or unique-index requirement, issue the START VIOLATIONS TABLE statement to start the violations and diagnostics tables. Do this before you use the SET Database Object Mode statement to set the database objects to the ENABLED or FILTERING database object mode.

## Effect on concurrent transactions

If the database has transaction logging, you must issue START VIOLATIONS TABLE in isolation. That is, no other transaction can be in progress on a target table when you issue START VIOLATIONS TABLE on that table within a transaction. Any transactions that start on the target table after the first transaction has issued the START VIOLATIONS TABLE statement will behave the same way as the first transaction with respect to the violations and diagnostics tables. That is, any constraint and unique-index violations by these subsequent transactions will be recorded in the violations and diagnostics tables.

For example, if transaction A operates on table **tab1** and issues a START VIOLATIONS TABLE statement on table **tab1**, the database server starts a violations table named **tab1\_vio** and filters any constraint or unique-index violations on table **tab1** by transaction A to table **tab1\_vio**. If transactions B and C start on table **tab1** after transaction A has issued the START VIOLATIONS TABLE statement, the database server also filters any constraint and unique-index violations by transactions B and C to table **tab1\_vio**.

The result is that all three transactions do not receive error messages about constraint and unique-index violations, even though transactions B and C do not expect this behavior. For example, if transaction B issues an INSERT or UPDATE statement that violates a check constraint on table **tab1**, the database server does not issue a constraint violation error to transaction B. Instead, the database server filters the nonconforming row (also called a "bad row") to the violations table without notifying transaction B that a data-integrity violation occurred.

You can prevent this situation from arising in Informix® by specifying `WITH ERRORS` when you specify the `FILTERING` mode in a `SET Database Object Mode`, `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX` statement. When multiple transactions operate on a table and the `WITH ERRORS` option is in effect, any transaction that violates a constraint or unique-index requirement on a target table receives a data-integrity error message.

## Stopping the Violations and Diagnostics Tables

After you use `START VIOLATIONS TABLE` to create an association between a target table and the violations and diagnostics tables, the only way to drop the association between the target table and the violations and diagnostics tables is to issue a `STOP VIOLATIONS TABLE` statement for the target table. For more information, see [STOP VIOLATIONS TABLE statement on page 1024](#).

## USING Clause

You can use the `USING` clause to declare explicit names for the violations table and for the diagnostics table.

If you omit the `USING` clause, the database server assigns names to the violation table and the diagnostics table. The system-assigned name of the violations table consists of the name of the target table followed by the string `_vio`. The name that the database server assigns to the diagnostics table consists of the name of the target table followed by the string `_dia`.

If you omit the `USING` clause, the maximum length of the name of the target table is 124 bytes.

## Using the MAX ROWS clause

The `MAX ROWS` clause specifies the maximum number of rows that the database server can insert into the diagnostics table when a single statement is executed on the target table. If you omit the `MAX ROWS` clause, no upper limit is imposed on the number of rows that can be inserted into the diagnostics table when a single statement is executed on the target table.

## Specifying the maximum number of rows in the diagnostics table

The following statement starts violations and diagnostics tables for the target table named `orders`. The `MAX ROWS` clause specifies the maximum number of rows that can be inserted into the diagnostics table when a single statement, such as an `INSERT` statement, is executed on the target table.

```
START VIOLATIONS TABLE FOR orders MAX ROWS 50000;
```

## Privileges required for starting violations or diagnostics tables

To start a violations or a diagnostics table for a target table, you must meet one of the following requirements:

- You must have the `DBA` privilege on the database.
- You must be the owner of the target table and also have the `Resource` privilege on the database.
- You must have the `Alter` privilege on the target table and also have the `Resource` privilege on the database.

## Structure of the violations table

When you issue `START VIOLATIONS TABLE` for a target table, the violations table that the statement creates has a predefined structure. This structure consists of the columns of the target table and three additional columns.

The following table shows the schema of the violations table.

| Column Name  | Data Type  | Column Description  |
|--|--|---|
| Same columns (in the same order) that appear in the target table | Same types as corresponding columns in the target table. | The violations table has the same schema as the target table, so that rows violating constraints or a unique-index during insert, update, and delete operations can be filtered to the violations table.  |
| <b>informix_tupleid</b>  | SERIAL   | Unique serial code for the nonconforming row  |
| <b>informix_optype</b>   | CHAR(1)  | The type of operation that caused this bad row. This column can have the following values:<br><br>I = Insert<br>D = Delete<br>O = Update (with original values in this row)<br>N = Update (with new values in this row)<br>S = SET Database Object Mode |
| <b>informix_reowner</b>  | CHAR(32)   | User who issued the statement that created this nonconforming row   |

If the target table of the `START VIOLATIONS TABLE` statement is protected by a security policy, the database server protects the violations table with same security policy. In this case, the schema of the violations table includes an `IDSSECURITYLABEL` column whose name and position among other columns corresponds to the `IDSSECURITYLABEL` column of the target table. When the violations table is created, any `SECURED WITH label` specifications that protect columns in the target table also protect the corresponding violations table columns.

Serial columns in the target table are converted to integer data types in the violations table.

Users can examine these nonconforming rows in the violations table, analyze the related rows that contain diagnostic information in the diagnostics table, and take corrective actions.

## Examples of START VIOLATIONS TABLE Statements

The following examples show different ways to execute the `START VIOLATIONS TABLE` statement.

### Violations and Diagnostics Tables with Default Names

The following statement starts violations and diagnostics tables for the target table named **cust\_subset**. The violations table is named **cust\_subset\_vio** by default, and the diagnostics table is named **cust\_subset\_dia** by default.

```
START VIOLATIONS TABLE FOR cust_subset;
```

## Violations and Diagnostics Tables with Explicit Names

The following statement starts a violations and diagnostics table for the target table named **items**. The USING clause assigns explicit names to the violations and diagnostics tables. The violations table is to be named **exceptions**, and the diagnostics table is to be named **reasons**.

```
START VIOLATIONS TABLE FOR items USING exceptions, reasons;
```

## Relationships Among the Target, Violations, and Diagnostics Tables

Users can take advantage of the relationships among the target, violations, and diagnostics tables to obtain diagnostic information about rows that cause data-integrity violations during INSERT, DELETE, and UPDATE statements. Each row of the violations table has at least one corresponding row in the diagnostics table.

- One row in the violations table is a copy of any row in the target table for which a data-integrity violation was detected. A row in the diagnostics table contains information about the nature of the data-integrity violation caused by the nonconforming row in the violations table.
- One row in the violations table has a unique serial identifier in the **informix\_tupleid** column. A row in the diagnostics table has the same serial identifier in its **informix\_tupleid** column.

A given row in the violations table can have more than one corresponding row in the diagnostics table. The multiple rows in the diagnostics table all have the same serial identifier in their **informix\_tupleid** column so that they are all linked to the same row in the violations table. Multiple rows can exist in the diagnostics table for the same row in the violations table because a nonconforming row in the violations table can cause more than one data-integrity violation.

For example, the same nonconforming row can violate a unique index for one column, a not-NULL constraint for another column, and a check constraint for a third column. In this case, the diagnostics table contains three rows for the single nonconforming row in the violations table. Each of these diagnostic rows identifies a different data-integrity violation that the nonconforming row in the violations table caused.

By joining the violations and diagnostics tables, the DBA or target-table owner can obtain diagnostic information about any or all nonconforming rows in the violations table. SELECT statements can perform these joins interactively, or you can write a program to perform them within transactions.

## Initial Privileges on the Violations Table

When you issue the START VIOLATIONS TABLE statement to create the violations table, the database server uses the set of privileges granted on the target table as a basis for granting privileges on the violations table. The database server follows different rules, however, when it grants each type of privilege.

The following table summarizes the circumstances under which the database server grants each type of privilege on the violations table.

### Privilege

#### Condition for Granting the Privilege

**Alter**

Alter privilege is not granted on the violations table. (Users cannot alter violations tables.)

**Index**

User has Index privilege on the violations table if the user has the Index privilege on the target table.

**Insert**

User has the Insert privilege on the violations table if the user has the Insert, Delete, or Update privilege on any column of the target table.

**Delete**

User has the Delete privilege on the violations table if the user has the Insert, Delete, or Update privilege on any column of the target table.

**Select**

User has the Select privilege on the **informix\_tupleid**, **informix\_optype**, and **informix\_recowner** columns of the violations table if the user has the Select privilege on any column of the target table.

User has the Select privilege on any other column of the violations table if the user has the Select privilege on the same column in the target table.

**Update**

User has the Update privilege on the **informix\_tupleid**, **informix\_optype**, and **informix\_recowner** columns of the violations table if the user has the Update privilege on any column of the target table.

(Even with the Update privilege on the **informix\_tupleid** column, however, the user cannot update this SERIAL column.)

User has the Update privilege on any other violations table column if the user has the Update privilege on the same column in the target table.

**References**

The References privilege is not granted on the violations table. (Users cannot add referential constraints to violations tables.)

The following rules apply to ownership of the violations table and privileges on the violations table:

- When the violations table is created, the owner of the target table becomes the owner of the violations table.
- The owner of the violations table automatically receives all table-level privileges on the violations table, including the Alter and References privileges. The database server, however, prevents the owner of the violations table from altering the violations table or adding a referential constraint to the violations table.
- You can use the GRANT and REVOKE statements to modify the initial set of privileges on the violations table.
- When you issue an INSERT, DELETE, or UPDATE statement on a target table that has a filtering-mode unique index or constraint defined on it, you must have the Insert privilege on the violations and diagnostics tables.

If you do not have the Insert privilege on the violations and diagnostics tables, the database server executes the INSERT, DELETE, or UPDATE statement on the target table provided that you have the necessary privileges on the

target table. The database server does not return an error concerning the lack of Insert privilege on the violations and diagnostics tables unless an integrity violation is detected during execution of the INSERT, DELETE, or UPDATE statement.

Similarly, when you issue a SET Database Object Mode statement to set a disabled constraint or disabled unique index to the enabled or filtering mode, and a violations table and diagnostics table exist for the target table, you must have the Insert privilege on the violations and diagnostics tables.

If you do not have the Insert privilege on the violations and diagnostics tables, the database server executes the SET Database Object Mode statement if you have the necessary privileges on the target table. The database server does not return an error concerning the lack of Insert privilege on the violations and diagnostics tables, unless an integrity violation is detected during the execution of the SET Database Object Mode statement.

- The grantor of the initial set of privileges on the violations table is the same as the grantor of the privileges on the target table.

For example, if user **henry** was granted the Insert privilege on the target table by both user **jill** and user **albert**, then the Insert privilege on the violations table is granted to **henry** both by **jill** and by **albert**.

- After the violations table is started, revoking a privilege on the target table from a user does not automatically revoke the same privilege on the violations table from that user. Instead, you must explicitly revoke the privilege on the violations table from the user.
- If you have fragment-level privileges on the target table, you have the corresponding fragment-level privileges on the violations table.

## Example of Privileges on the Violations Table

The following example illustrates how the initial set of privileges on a violations table is derived from the current set of privileges on the target table. Assume that a table named **cust\_subset** consists of the following columns: **ssn** (customer Social Security number), **fname** (customer first name), **lname** (customer last name), and **city** (city in which the customer lives).

The following set of privileges exists on the **cust\_subset** table:

- User **barbara** has the Insert and Index privileges on the table. They also have the Select privilege on the **ssn** and **lname** columns.
- User **carrie** has the Update privilege on the **city** column. They also have the Select privilege on the **ssn** column.
- User **danny** has the Alter privilege on the table.

Now user **alvin** starts a violations table named **cust\_subset\_vio** and a diagnostics table named **cust\_subset\_diags** for the **cust\_subset** table:

```
START VIOLATIONS TABLE FOR cust_subset
  USING cust_subset_vio, cust_subset_diags;
```

The database server grants the following set of initial privileges on the **cust\_subset\_vio** violations table:

- User **alvin** is the owner of the violations table, so they have all table-level privileges on the table.
- User **barbara** has the Insert, Delete, and Index privileges on the table.

User **barbara** has the Select privilege on five columns of the violations table: the **ssn**, the **lname**, the **informix\_tupleid**, the **informix\_optype**, and the **informix\_reowner** columns.

- User **carrie** has Insert and Delete privileges on the violations table.

User **carrie** has the Update privilege on four columns of the violations table: the **city**, the **informix\_tupleid**, the **informix\_optype**, and the **informix\_reowner** columns. They cannot, however, update the **informix\_tupleid** column (because this is a SERIAL column).

User **carrie** has the Select privilege on four columns of the violations table: the **ssn** column, the **informix\_tupleid** column, the **informix\_optype** column, and the **informix\_reowner** column.

- User **danny** has no privileges on the violations table.

## Using the Violations Table

The following rules concern the structure and use of the violations table:

- Every pair of update rows in the violations table has the same value in the **informix\_tupleid** column to indicate that both rows refer to the same row in the target table.
- If the target table has columns named **informix\_tupleid**, **informix\_optype**, or **informix\_reowner**, the database server attempts to generate alternative names for these columns in the violations table by appending a digit to the end of the column name (for example, **informix\_tupleid1**). If this fails, an error is returned, and no violations table is started for the target table.
- When a table functions as a violations table, it cannot have triggers or constraints defined on it.
- When a table functions as a violations table, users can create indexes on it, even though the existence of an index affects performance. Unique indexes on the violations table cannot be set to FILTERING database object mode.
- If a target table has a violations and diagnostics table associated with it, dropping the target table in cascade mode (the default mode) causes the violations and diagnostics tables to be dropped also. If the target table is dropped in the restricted mode, the DROP TABLE operation fails (because the violations and diagnostics tables exist).
- After a violations table is started for a target table, ALTER TABLE cannot add, modify, or drop columns of the violations, diagnostics, or target tables. Before you can alter any of these tables, you must issue a STOP VIOLATIONS TABLE statement for the target table.
- The database server does not clear out the contents of the violations table before or after it uses the violations table during an INSERT, UPDATE, DELETE, or SET Database Object Mode operation.
- If a target table has a filtering-mode constraint or unique index defined on it and a violations table associated with it, users cannot insert into the target table by selecting from the violations table. Before you insert rows into the target table by selecting from the violations table, you must take one of the following steps:
  - You can set the constraint or unique index to DISABLED mode.
  - You can issue STOP VIOLATIONS TABLE for the target table.

If it is inconvenient to take either of these steps, but you intend to copy records from the violations table into the target table, a third option is to select from the violations table into a temporary table and then insert the contents of the temporary table into the target table.

- If the target table that is specified in the START VIOLATIONS TABLE statement is fragmented, the violations table has the same fragmentation strategy as the target table. Each fragment of the violations table is stored in the same dbspace partition as the corresponding fragment of the target table.
- Once a violations table is started for a target table, you cannot use the ALTER FRAGMENT statement to alter the fragmentation strategy of the target table or the violations table.
- If the target table specified in the START VIOLATIONS TABLE statement is not fragmented, the database server places the violations table in the same dbspace as the target table.
- If the target table has BYTE or TEXT columns, BYTE or TEXT data values in the violations table are created in the same blob space that stores the BYTE or TEXT data in the target table.

## Example of a Violations Table

To start a violations and diagnostics table for the target table named **customer** in the demonstration database, enter the following statement:

```
START VIOLATIONS TABLE FOR customer;
```

Because you include no USING clause, the violations table is named **customer\_vio** by default. The **customer\_vio** table includes these five columns:

| Column One   | Column Two | Column Three | Column Four | Column Five      |
|--------------|------------|--------------|-------------|------------------|
| customer_num | company    | city         | zipcode     | informix_tupleid |
| fname        | address1   | state        | phone       | informix_optype  |
| lname        | address2   |              |             | informix_reowner |

The **customer\_vio** table has the same table definition as the **customer** table except that the **customer\_vio** table has three additional columns that contain information about the operation that caused the nonconforming row.

## Structure of the diagnostics table

When you issue a START VIOLATIONS TABLE statement for a target table, the diagnostics table that the statement creates has a predefined structure. This structure is independent of the structure of the target table.

The following table shows the schema of the diagnostics table.

| Column Name             | Data Type | Description   |
|-------------------------|-----------|---|
| <b>informix_tupleid</b> | INTEGER   | Implicitly refers to <b>informix_tupleid</b> column values in the violations table. This relationship, however, is not declared as a foreign-key to primary-key relationship. |
| <b>objtype</b>          | CHAR(1)   | Identifies the type of violation. This column can have the following values:  |

| Column Name     | Data Type       | Description   |
|-----------------|-----------------|---|
|                 |                 | C = Constraint violation<br>I = Unique-index violation  |
| <b>objowner</b> | CHAR(32)        | Identifies the owner of the constraint or index for which an integrity violation was detected |
| <b>objname</b>  | VARCHAR(128, 0) | Contains the name of the constraint or index for which an integrity violation was detected    |

## Initial privileges on the diagnostics table

When the START VIOLATIONS TABLE statement creates the diagnostics table, the set of access privileges granted on the target table are a basis for granting privileges on the diagnostics table. The database server follows different rules, however, when it grants each type of privilege.

The following table explains the circumstances under which the database server grants each privilege on the diagnostics table.

### Privilege

#### Condition for Granting the Privilege

#### Insert

User has the Insert privilege on the diagnostics table if the user has the Insert, Delete, or Update privilege on any column of the target table.

#### Delete

User has the Delete privilege on the diagnostics table if the user has the Insert, Delete, or Update privilege on any column of the target table.

#### Select

User has the Select privilege on the diagnostics table if the user has the Select privilege on any column in the target table.

#### Update

User has the Update privilege on the diagnostics table if the user has the Update privilege on any column in the target table.

#### Index

User has the Index privilege on the diagnostics table if the user has the Index privilege on the target table.

#### Alter

Alter privilege is not granted on the diagnostics table.

(Users cannot alter the schema of diagnostics tables.)

## References

References privilege is not granted on the diagnostics table.

(Users cannot define referential constraints on diagnostics tables.)

The following rules concern access privileges on the diagnostics table:

- When the diagnostics table is created, the owner of the target table becomes the owner of the diagnostics table.
- The owner of the diagnostics table automatically receives all table-level privileges on the diagnostics table, including the Alter and References privileges. The database server, however, prevents the owner of the diagnostics table from altering the diagnostics table or adding a referential constraint to the diagnostics table.
- You can use the GRANT and REVOKE statements to modify the initial set of privileges on the diagnostics table.
- For INSERT, DELETE, or UPDATE operations on a target table that has a filtering-mode unique index or constraint defined on it, you must have the Insert privilege on the violations and diagnostics tables.

If you do not have the Insert privilege on the violations and diagnostics tables, the database server executes the INSERT, DELETE, or UPDATE statement on the target table, provided you have the necessary privileges on the target table. The database server does not return an error concerning the lack of Insert privilege on the violations and diagnostics tables unless an integrity violation is detected during execution of the INSERT, DELETE, or UPDATE statement.

Similarly, when you issue a SET Database Object Mode statement to set a disabled constraint or disabled unique index to the enabled or filtering mode, and a violations table and diagnostics table exist for the target table, you must have the Insert privilege on the violations and diagnostics tables.

If you do not have the Insert privilege on the violations and diagnostics tables, the database server executes the SET Database Object Mode statement, provided you have the necessary privileges on the target table. The database server does not return an error concerning the lack of Insert privilege on the violations and diagnostics tables unless an integrity violation is detected during the execution of the SET Database Object Mode statement.

- The grantor of the initial set of privileges on the diagnostics table is the same as the grantor of the privileges on the target table. For example, if the user **jenny** was granted the Insert privilege on the target table by both the user **wayne** and the user **laurie**, both user **wayne** and user **laurie** grant the Insert privilege on the diagnostics table to user **jenny**.
- Once a diagnostics table is started for a target table, revoking a privilege on the target table from a user does not automatically revoke the same privilege on the diagnostics table from that user. Instead you must explicitly revoke the privilege on the diagnostics table from the user.
- If you have fragment-level privileges on the target table, you have the corresponding table-level privileges on the diagnostics table.

The next example illustrates how the initial set of privileges on a diagnostics table is derived from the current privileges on the target table. Assume that you have a table called **cust\_subset** that holds **customer** data. This table consists of the following columns: **ssn** (social security number), **fname** (first name), **lname** (last name), and **city** (city in which the customer lives). The following set of access privileges exists on the **cust\_subset** table:

- User **alvin** is the owner of the table.
- User **barbara** has the Insert and Index privileges on the table. She also has the Select privilege on the **ssn** and **lname** columns.
- User **danny** has the Alter privilege on the table.
- User **carrie** has the Update privilege on the **city** column. She also has the Select privilege on the **ssn** column.

Now user **alvin** starts a violations table named **cust\_subset\_viols** and a diagnostics table named **cust\_subset\_diags** for the **cust\_subset** table:

```
START VIOLATIONS TABLE FOR cust_subset
  USING cust_subset_viols, cust_subset_diags;
```

The database server grants the following set of initial privileges on the **cust\_subset\_diags** diagnostics table:

- User **alvin** is the owner of the diagnostics table, so he has all table-level privileges on the table.
- User **barbara** has the Insert, Delete, Select, and Index privileges on the diagnostics table.
- User **carrie** has the Insert, Delete, Select, and Update privileges on the diagnostics table.
- User **danny** has no privileges on the diagnostics table.

## Using the Diagnostics Table

The following issues concern the structure and use of the diagnostics table.

- The MAX ROWS clause of the START VIOLATIONS TABLE statement sets a limit on the number of rows that can be inserted into the diagnostics table when you execute a single statement, such as an INSERT or SET Database Object Mode statement, on the target table.
- The MAX ROWS clause limits the number of rows only for operations in which the table functions as a diagnostics table.
- When a table functions as a diagnostics table, it cannot have triggers or constraints defined on it.
- When a table functions as a diagnostics table, users can create indexes on the table, but the existence of an index affects performance. You cannot set unique indexes on a diagnostics table to FILTERING database object mode.
- If a target table has a violations and diagnostics table associated with it, dropping the target table in cascade mode (the default mode) causes the violations and diagnostics tables to be dropped also.
- If the target table is dropped in restricted mode, the DROP TABLE operation fails (because the violations and diagnostics tables exist).
- Once a violations table is started for a target table, you cannot use the ALTER TABLE statement to add, modify, or drop columns in the target table, violations table, or diagnostics table. Before you can alter any of these tables, you must issue a STOP VIOLATIONS TABLE statement for the target table.
- The database server does not clear out the contents of the diagnostics table before or after it uses the diagnostics table during an Insert, Update, Delete, Merge, SET CONSTRAINTS, or SET INDEXES operation.
- If the target table that is specified in the START VIOLATIONS TABLE statement is fragmented, the diagnostics table is fragmented with a round-robin strategy over the same tablespaces in which the target table is fragmented.

To start a violations and diagnostics table for the target table named **stock** in the demonstration database, enter the following statement:

```
START VIOLATIONS TABLE FOR stock;
```

Because your `START VIOLATIONS TABLE` statement does not include a `USING` clause, the diagnostics table is named **stock\_dia** by default. The **stock\_dia** table includes the following two columns:

| Column One               | Column Two       |
|--------------------------|------------------|
| informix_tupleid objtype | objowner objname |

This list of columns shows an important difference between the diagnostics table and violations table for a target table. Whereas the violations table has a matching column for every column in the target table, the columns of the diagnostics table do not match any columns in the target table. The diagnostics table created by any `START VIOLATIONS TABLE` statement always has the same columns, with the same column names and data types.

For information on the relationship between the diagnostics table and the violations table, see [Relationships Among the Target, Violations, and Diagnostics Tables on page 1016](#).

## STOP VIOLATIONS TABLE statement

Use the `STOP VIOLATIONS TABLE` statement to drop the association between a target table, its violations table, and its diagnostics table. This statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

#### `STOP VIOLATIONS TABLE FOR`

*'owner'* .

*table*

| Element      | Description   | Restrictions  | Syntax                                  |
|--------------|---|---|---|
| <i>owner</i> | The owner of <i>table</i>   | Must own the table  | <a href="#">Owner name on page 1488</a> |
| <i>table</i> | Name of a target table whose association with the violations and diagnostics table is to be dropped. No default value exists. | Must be a local table that has an associated violations table and a diagnostics table | <a href="#">Identifier on page 1456</a> |

### Usage

The `STOP VIOLATIONS TABLE` statement drops the association between the target table, the violations table, and the diagnostics table. After you issue this statement, the former violations and diagnostics tables continue to exist, but they no longer function as violations and diagnostics tables for the target table. They now have the status of regular database tables instead of violations and diagnostics tables for the target table. You must issue the `DROP TABLE` statement to drop these two tables explicitly.

When DML operations (INSERT, DELETE, or UPDATE) cause data-integrity violations for rows of the target table, the nonconforming rows are no longer filtered to the former violations table, and diagnostic information about the data-integrity violations is not placed in the former diagnostics table.

---

[Modes for constraints and unique indexes on page 876](#)

[SET Database Object Mode statement on page 871](#)

[START VIOLATIONS TABLE statement on page 1011](#)

## Example of Stopping the Violations and Diagnostics Tables

Assume that a target table named **cust\_subset** has an associated violations table named **cust\_subset\_vio** and an associated diagnostics table named **cust\_subset\_dia**. To drop the association between the target table and the violations and diagnostics tables, enter the following statement:

```
STOP VIOLATIONS TABLE FOR cust_subset;
```

This deletes the row in the **sysviolations** system catalog table that had registered the former association. Subsequent DML operations on the target **cust\_subset** table will no longer cause the database server to insert information about nonconforming rows into its former violations table or diagnostics table.

## Example of Dropping the Violations and Diagnostics Tables

After you execute the STOP VIOLATIONS TABLE statement in the preceding example, the **cust\_subset\_vio** and the **cust\_subset\_dia** tables continue to exist, but they are no longer associated with the **cust\_subset** table. Instead they now have the status of regular database tables. To drop these two tables, enter the following statements:

```
DROP TABLE cust_subset_vio;  
DROP TABLE cust_subset_dia;
```

If you had previously issued the DROP TABLE statement without the RESTRICT keyword to successfully drop the **cust\_subset** table, then the statements above would not be necessary, because dropping the target table in cascade mode implicitly drops any associated violations table and diagnostics table.

## Privileges Required for Stopping a Violations Table

To stop a violations or a diagnostics table for a given target table, you must meet one of the following requirements:

- You must have the DBA privilege on the database.
- You must be the owner of the target table and have the Resource privilege on the database.
- You must have the Alter privilege on the target table and the Resource privilege on the database.

## TRUNCATE statement

Use the TRUNCATE statement to quickly delete all rows from a local table and free the associated storage space. You can optionally reserve the space for the same table and its indexes. Only Informix® supports this implementation of the TRUNCATE statement, which is an extension to the ANSI/ISO standard for SQL.

### Syntax

```

      .- TABLE -.
>>- TRUNCATE +-----+-----+-----+-----+ table +-----+
              '- 'owner' -- . --' '- synonym -'

      .- DROP STORAGE --.
>+-----+ +-----+-----+-----+<
  '- REUSE STORAGE -'   '- KEEP STATISTICS -'

```

| Element        | Description  | Restrictions                                 | Syntax                                  |
|----------------|--|--|---|
| <i>owner</i>   | Owner of <i>table</i> or <i>synonym</i>  | See <b>Usage</b> notes.                      | <a href="#">Owner name on page 1488</a> |
| <i>synonym</i> | Synonym for the table from which to remove all data                                  | Must exist, and USETABLENAME must not be set | <a href="#">Identifier on page 1456</a> |
| <i>table</i>   | Name of table from which to remove all data and all B-tree structures of its indexes | Must exist in the database                   | <a href="#">Identifier on page 1456</a> |

### Usage

The TRUNCATE statement rapidly deletes from a local table all active data rows and the B-tree structures of indexes on the table. You have the option of releasing the storage space that was occupied by the rows and index extents, or of reusing the same space when the table is subsequently repopulated with new rows.

To execute the TRUNCATE statement, at least one of the following conditions must be satisfied:

- You are the owner of the table.
- You hold the Delete access privilege on the table.
- You hold the DBA access privilege on the current database.

If an enabled Delete trigger is defined on the table, you must also hold the Alter privilege on the table, even though the TRUNCATE statement does not activate triggers.

Although it requires the Delete privilege for a non-DBA user who does not own the table, TRUNCATE is a data definition language (DDL) statement. Like other DDL statements, TRUNCATE cannot operate on any table outside the database to which you are connected, nor on a table that a concurrent session is reading in Dirty Read isolation mode.

Informix® always logs the TRUNCATE operation, even for a non-logging table. In databases that support transaction logging, only the COMMIT WORK or ROLLBACK WORK statement of SQL is valid after the TRUNCATE statement within the same transaction. Here the ROLLBACK statement must cancel the entire transaction that includes the TRUNCATE

statement. Informix® issues an error if ROLLBACK TO SAVEPOINT (or any other SQL statement except for COMMIT WORK or ROLLBACK WORK without the TO SAVEPOINT clause) immediately follows the TRUNCATE statement.

When you successfully rollback the TRUNCATE statement, no rows are removed from the table, and the storage extents that hold the rows and index partitions continue to be allocated to the table. Only databases with transaction logging can support the ROLLBACK WORK statement.

After the TRUNCATE statement successfully executes, Informix® automatically updates the statistics and distributions for the table and for its indexes in the system catalog to show no rows in the table nor in its dbspace partitions. It is not necessary to run the UPDATE STATISTICS statement immediately after you commit the TRUNCATE statement. If the KEEP STATISTICS operation is used, then TRUNCATE TABLE does not update the system catalog.

If the table that the TRUNCATE statement specifies is a typed table, a successful TRUNCATE operation removes all the rows and B-tree structures from that table and from all its subtables within the table hierarchy.

The TRUNCATE statement does not reset the serial value of SERIAL, BIGSERIAL, or SERIAL8 columns. To reset the counter of a serial column, use the MODIFY clause of the ALTER TABLE statement, either before or after you execute the TRUNCATE statement.

#### Related reference

[DELETE statement on page 486](#)

[DROP TABLE statement on page 531](#)

## The TABLE Keyword

The TABLE keyword has no effect on this statement, but it can be included to make your code more legible for human readers. Both of the following statements have the same effect, deleting all rows and any related index data from the **customer** table:

```
TRUNCATE TABLE customer;
```

```
TRUNCATE customer;
```

## The Table Specification

You must specify the name or synonym of a table in the local database to which you are currently connected. If the **USETABLENAME** environment variable is set, you must use the name of the table, rather than a synonym. The table can be of type STANDARD, RAW, or TEMP, but you cannot specify the name or synonym of a view, or an object that the CREATE EXTERNAL TABLE statement defined. (Categories of tables that are not valid with TRUNCATE are listed in the section [Restrictions on the TRUNCATE statement on page 1030](#).)

In a database that is ANSI-compliant, you must specify the *owner* qualifier if you are not the owner of the *table* or *synonym*.

After the TRUNCATE statement begins execution, Informix® attempts to place an exclusive lock on the specified table, to prevent other sessions from locking the table until the TRUNCATE statement is committed or rolled back. Exclusive locks are also applied to any dependent tables of the truncated table within a table hierarchy.

While concurrent sessions that use the Dirty Read isolation level are reading the table, however, the TRUNCATE statement fails with an RSAM -106 error. To reduce this risk, you can set the **IFX\_DIRTY\_WAIT** environment variable to specify that the TRUNCATE operation wait for a specified number of seconds for Dirty Read transactions to commit or rollback.

## The STORAGE specification

The optional DROP STORAGE or REUSE STORAGE keywords specify what action the database server takes with the storage extents of the table when the TRUNCATE operation begins. If you omit this specification, the DROP STORAGE option is the default.

Using the default or explicit DROP STORAGE option, a successful TRUNCATE statement releases all but the first extent among the extents currently allocated to the table and to its indexes. You can display the current list of extents with the `oncheck -pT table` command. If your table has only one extent, no space will be freed.

For the following table, for example, four default eight-page extents were merged into what is now the first extent. There is also a second, larger extent:

| Extents      |               |      |          |       |
|--------------|---------------|------|----------|-------|
| Logical Page | Physical Page | Size | Physical | Pages |
| 0            | 1:104455      | 32   |          | 32    |
| 32           | 1:104495      | 4576 |          | 4576  |

After the TRUNCATE statement runs, output from the same `oncheck` command displays this:

| Extents      |               |      |          |       |
|--------------|---------------|------|----------|-------|
| Logical Page | Physical Page | Size | Physical | Pages |
| 0            | 1:104455      | 32   |          | 32    |

Alternatively, if you intend to keep the same storage space allocated to the same table for subsequently loaded data, specify the REUSE STORAGE keywords to prevent the space from being deallocated. The REUSE STORAGE option of TRUNCATE can make storage management more efficient in applications where the same table is periodically emptied and reloaded with new rows.

The following example truncates the **state** table and frees all of its extents except the first extent:

```
TRUNCATE TABLE state DROP STORAGE;
```

The following example truncates the same table but removes only the actual data. All extents stay the same.

```
TRUNCATE TABLE state REUSE STORAGE;
```

Whether you specify DROP STORAGE or REUSE STORAGE, any out-of-row data values are released for all rows of the table when the TRUNCATE transaction is committed. Storage occupied by any BLOB or CLOB values that become unreferenced in the TRUNCATE transaction is also released.

## The AM\_TRUNCATE Purpose Function

Informix® provides built-in **am\_truncate** purpose functions for its primary access methods that support TRUNCATE operations on columns of permanent and temporary tables. It also provides a built-in **am\_truncate** purpose function for its secondary access method for TRUNCATE operations on B-tree indexes.

For the TRUNCATE statement to work correctly in a virtual table interface (VTI) table requires a valid **am\_truncate** purpose function in the primary access method for the data type of the VTI table. To register a new primary access method in the database, use the CREATE PRIMARY ACCESS\_METHOD statement of SQL:

```
CREATE PRIMARY ACCESS_METHOD vti(
  AM_GETNEXT = vti_getnext
  AM_TRUNCATE = vti_truncate
  ...);
```

You can also use the ALTER ACCESS\_METHOD statement to add a valid **am\_truncate** purpose function to an existing access method that has no **am\_truncate** purpose function:

```
ALTER ACCESS_METHOD abc (ADD AM_TRUNCATE = abc_truncate);
```

In these examples, the **vti\_truncate** and **abc\_truncate** functions must be routines that support the functionality of the AM\_TRUNCATE purpose option keyword, and that were previously registered in the database by the CREATE FUNCTION or CREATE ROUTINE FROM statement.

## Performance Advantages of TRUNCATE

The TRUNCATE statement is not equivalent to DROP TABLE. After TRUNCATE successfully executes, the specified *table* and all its columns and indexes are still registered in the database, but with no rows of data. In information management applications that require replacing all of the records in a table after some time interval, TRUNCATE requires fewer updates to the system catalog than the equivalent DROP TABLE, CREATE TABLE, and any additional DDL statements to redefine any synonyms, views, constraints, triggers, privileges, fragmentation schemes, and other attributes and associated database objects of the table.

In contexts where no existing rows of a table are needed, the TRUNCATE statement is typically far more efficient than using the DELETE statement with no WHERE clause to empty the table, because TRUNCATE requires fewer resources and less logging overhead than DELETE:

- DELETE FROM *table* deletes each row as a separately logged operation. If indexes exist on the table, each index must be updated when a row is deleted, and this update is also logged for each row. If an enabled Delete trigger is defined on the table, its triggered actions must also be executed and logged.
- TRUNCATE *table* performs the removal of all rows and of the B-tree structures of every index on the table as a single operation, and writes a single entry in the logical log when the transaction that includes TRUNCATE is committed or rolled back. The triggered action of any enabled trigger is ignored.

These performance advantages of TRUNCATE over DELETE are reduced when the table has one or more columns with the following attributes:

- Any simple large object data types stored in blobspaces
- Any BLOB, CLOB, complex, or user-defined types stored in sbspaces
- Any opaque types for which a **destroy** support function is defined.

Each of these features require the database server to read each row of the table, substantially reducing the speed of TRUNCATE.

If a table includes one or more UDTs for which you have registered an **am\_truncate()** purpose function, then the performance difference between TRUNCATE and DELETE would reflect the relative costs of invoking the **am\_truncate** interface once for TRUNCATE versus invoking the **destroy()** support function for each row.

As listed in the next section, certain conditions cause TRUNCATE to fail with an error. Some of these conditions have no effect on DELETE operations, so in those cases you can remove all rows more efficiently with a DELETE statement, as in the following operation on the **customer** table:

```
DELETE customer;
```

The FROM keyword that immediately follows DELETE can be omitted, as in this example, only if the **DELIMITIDENT** environment variable is set.

## Restrictions on the TRUNCATE statement

The TRUNCATE statement fails if any of the following conditions exist:

- The user does not hold the Delete access privilege on the table.
- The table has an enabled Delete trigger, but the user lacks the Alter privilege.
- The specified table or synonym does not exist in the local database.
- The table was defined by the CREATE EXTERNAL TABLE statement.
- The specified synonym does not reference a table in the local database.
- The statement specifies a synonym for a local table, but the **USETABLENAME** environment variable is set.
- The statement specifies the name of a view or a synonym for a view.
- The table is a system catalog table or a system-monitoring interface (SMI) table.
- An R-tree index is defined on the table.
- The table is a virtual table (or has a virtual-index interface) for which no valid **am\_truncate** access method exists in the database.
- An Enterprise Replication replicate that is not a master replicate is defined on the table. (For more information about replicates, see the .)
- A shared or exclusive lock on the table already exists.
- One or more cursors are open on the table.
- A concurrent session with Dirty Read isolation level is reading the table.
- Another table, with at least one row, has an enabled foreign-key constraint on the specified table. (An enabled foreign key constraint of another table that has no rows, however, has no effect on a TRUNCATE operation.)

## UNLOAD statement

Use the UNLOAD statement to write the rows retrieved by a SELECT statement to an operating-system file. The UNLOAD statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

Only DB-Access supports the UNLOAD statement.

**UNLOAD TO***'filename'*  
**DELIMITER***'delimiter'*  
 SELECT Statement <sup>459</sup>  
*variable*

| Element          | Description  | Restrictions                                      | Syntax                                     |
|------------------|--|---|--|
| <i>delimiter</i> | Quoted string to specify the field delimiter character in <i>filename</i> file               | See <a href="#">DELIMITER Clause on page 1035</a> | <a href="#">Quoted String on page 1424</a> |
| <i>filename</i>  | Operating-system file to receive the rows. Default <i>pathname</i> is the current directory. | See <a href="#">UNLOAD TO File on page 1031</a> . | <a href="#">Quoted String on page 1424</a> |
| <i>variable</i>  | Host variable that contains the text of a valid SELECT statement                             | Must have been declared as a character data type  | Language- specific                         |

## Usage

 **Important:** Use the UNLOAD statement only with DB-Access.

The UNLOAD statement copies to a file the rows retrieved by a query. You must have the Select privilege on all columns specified in the SELECT statement. For information on database-level and table-level privileges, see [GRANT statement on page 592](#).

You can specify a literal SELECT statement or a character variable that contains the text of a SELECT statement. (See [SELECT statement on page 768](#).)

The following example unloads rows whose value of `customer.customer_num` is greater than or equal to `138`, and writes them to a file named `cust_file`:

```
UNLOAD TO 'cust_file' DELIMITER '!'
SELECT * FROM customer WHERE customer_num >= 138;
```

The resulting output file, `cust_file`, contains two rows of data values:

```
138!Jeffery!Padgett!Wheel Thrills!3450 EL Camino!Suite 10!Palo Alto!CA!94306!!
139!Linda!Lane!Palo Alto Bicycles!2344 University!!Palo Alto!CA!94301!
(415)323-5400
```

## UNLOAD TO File

The UNLOAD TO file, as specified by the *filename* parameter, receives the retrieved rows.

You can use an UNLOAD TO file as input to a LOAD statement.

### UNLOAD TO data formats in the default U.S. English locale

In the default locale, data values have these formats in the UNLOAD TO file.

| Data Type                               | Output Format   |
|---|---|
| BOOLEAN                                 | BOOLEAN values appear as either t for TRUE or f for FALSE.  |
| Character                               | If a character field contains the delimiter, Informix® products automatically escape it with a backslash ( \ ) to prevent interpretation as a special character. In the UNLOAD TO file, a literal backslash character is represented as two consecutive backslash characters ( \ \ ). If you use the LOAD statement of DB-Access to insert the rows into a table, the backslash escape characters are automatically stripped from that table. |
| Collections                             | A collection is unloaded with its values between braces ( { } ) and a delimiter between each element. For more information, see <a href="#">Unloading Complex Types on page 1035</a> .  |
| DATE                                    | DATE values are represented as <i>mm/dd/yyyy</i> (or the default format for the database locale), where <i>mm</i> is the month (January = 1, and so on), <i>dd</i> is the day, and <i>yyyy</i> is the year. If you have set the <b>GL_DATE</b> or <b>DBDATE</b> environment variable, the UNLOAD statement uses the specified date format for DATE values.  |
| DATETIME,<br>INTERVAL                   | Literal DATETIME and INTERVAL values appear as digits and delimiters, without keyword qualifiers, in the default format <i>yyyy-mm-dd hh:mi:ss.fff</i> . Time units outside the declared precision are omitted. If the <b>GL_DATETIME</b> or <b>DBTIME</b> environment variable is set, DATETIME values appear in the specified format.   |
| DECIMAL,<br>MONEY                       | Values are unloaded with no leading currency symbol. In the default locale, comma ( , ) is the <i>thousands</i> separator and period ( . ) is the decimal separator. If <b>DBMONEY</b> is set, UNLOAD uses its specified separators and currency format for MONEY values.   |
| NULL                                    | NULL appears as two delimiters with no characters between them.   |
| Number                                  | Values appear as literals, with no leading blanks. For BIGINT, INTEGER, INT8, and SMALLINT data types, zero appears as 0, For MONEY, FLOAT, SMALLFLOAT, and DECIMAL data types, zero appears as 0.0.  |
| ROW types<br>(named and<br>unnamed)     | A ROW type is unloaded with its values enclosed between parentheses and a field delimiter separating each element. For more information, see <a href="#">Unloading Complex Types on page 1035</a> .   |
| Simple large<br>objects (TEXT,<br>BYTE) | TEXT and BYTE columns are unloaded directly into the UNLOAD TO file. BYTE values appear in ASCII hexadecimal form, with no added white space or newline characters. For more information, see <a href="#">Unloading Simple Large Objects on page 1033</a> .   |

| Data Type                              | Output Format  |
|--|--|
| Smart large objects (CLOB, BLOB)       | CLOB and BLOB columns are unloaded into a separate operating-system file (for each column) on the client computer. The CLOB or BLOB field in the UNLOAD TO file contains the name of this file. For more information, see <a href="#">Unloading Smart Large Objects on page 1034</a> .   |
| User-defined data types (opaque types) | Opaque types must have an <b>export( )</b> support function defined. They need special processing to copy data from the internal format of the opaque data type to the UNLOAD TO file format. An <b>exportbinary( )</b> support function might also be required for data in binary format. The data in the UNLOAD TO file would correspond to the format that the <b>export( )</b> or <b>exportbinary( )</b> support function returns. |

### UNLOAD TO data formats in nondefault locales

In nondefault locales, DATE, DATETIME, MONEY, and numeric column values have formats that the locale supports for these data types. For more information, see the *Informix® GLS User's Guide*. For more information on **DBDATE**, **DBMONEY**, and **DBTIME** environment variables, refer to the *Informix® Guide to SQL: Reference*.

In databases that use a nondefault locale, if the **GL\_DATETIME** environment variable has a nondefault setting, the **USE\_DTENV** environment variable must be set to 1 before the UNLOAD statement can correctly unload localized DATETIME values from the database table, or from view, or from a table object defined by the EXTERNAL TABLE statement. For more information on the **GL\_DATETIME**, **GL\_DATE**, and **USE\_DTENV** environment variables, refer to the *Informix® GLS User's Guide*.

### Unloading Character Columns

In unloading files that contain VARCHAR or NVARCHAR columns, trailing blanks are retained in VARCHAR, LVARCHAR, or NVARCHAR fields. Trailing blanks are discarded when CHAR or NCHAR columns are unloaded.

For CHAR, VARCHAR, NCHAR, and NVARCHAR columns, an empty string (a data string of zero length, containing no characters) appears in the UNLOAD TO file as the four bytes | \ | (delimiter, backslash, blank space, delimiter).

Some earlier releases of Informix® database servers used || (consecutive delimiters) to represent the empty string in LOAD and UNLOAD operations. In this release, however, || only represents NULL values in CHAR, VARCHAR, LVARCHAR, NCHAR, and NVARCHAR columns.

### Unloading Simple Large Objects

The database server writes BYTE and TEXT values directly into the UNLOAD TO file. BYTE values are written in hexadecimal dump format with no added blank spaces or new line characters. The logical length of an UNLOAD TO file containing BYTE data can therefore be long and difficult to print or edit.

If you are unloading files that contain simple-large-object data types, do not use characters that can appear in BYTE or TEXT values as delimiters in the UNLOAD TO file. See also the section [DELIMITER Clause on page 1035](#).

The database server handles any required code-set conversions for TEXT data. For more information, see the *Informix® GLS User's Guide*.

If you are unloading files that contain simple-large-object data types, objects smaller than 10 kilobytes are stored temporarily in memory. You can adjust the 10-kilobyte setting to a larger setting with the **DBBLOBBUF** environment variable. BYTE or TEXT values larger than the default or the **DBBLOBBUF** setting are stored in a temporary file. For additional information about **DBBLOBBUF**, see the *Informix® Guide to SQL: Reference*.

## Unloading Smart Large Objects

The database server unloads smart large objects (from BLOB or CLOB columns) into a separate operating-system file for each column, in the same directory on the client computer as the UNLOAD TO file. All the smart blobs in the same column are stored in a single file. The filename has one of these formats:

- For a BLOB value: `blob#####`
- For a CLOB value: `clob#####`

In the preceding formats, the pound ( # ) symbols represent the digits of the unique hexadecimal smart-large-object identifier of the first smart large object in the file. The maximum number of digits for a smart-large-object identifier is 17. Most smart large objects, however, would have an identifier with fewer digits.

When the database server unloads the first smart large object, it creates the appropriate BLOB or CLOB client file with the hexadecimal identifier of the smart large object. If additional smart-large-object values are present in the same column, the database server writes their values to the same file, and lists in the UNLOAD TO file ( **\*.unl** ) the sbspace, chunk, and page numbers, and smart large object identifier, for each BLOB or CLOB value in the file.

The following example shows an UNLOAD TO file entry for two smart large object values from the same column:

```
Object # 1
Space Chunk Page = [5,6,3] Object ID = 1192071051

Object #2
Space Chunk Page = [5,6,4] Object ID = 1192071050

both rows unloaded
```

In an UNLOAD TO file, a BLOB or CLOB column value appears in this format:

```
start_off,length,client_path
```

Here *start\_off* is the starting offset (in hexadecimal format) of the smart-large-object value within the client file, *length* is the length (in hexadecimal) of the BLOB or CLOB value, and *client\_path* is the pathname for the client file. No blank spaces can appear between these values. If a CLOB value is 512 bytes long and is at offset 256 in the `/usr/apps/clob9ce7.318` file, for example, then the CLOB value appears as follows in the UNLOAD TO file:

```
|100,200,/usr/apps/clob9ce7.318|
```

If a BLOB or CLOB column value occupies an entire client file, the CLOB or BLOB column value appears as follows in the UNLOAD TO file:

```
client_path
```

For example, if a CLOB value occupies the entire file `/usr/apps/clob9ce7.318`, the CLOB value appears as follows in the UNLOAD TO file:

```
|/usr/apps/clob9ce7.318|
```

For locales that support multibyte code sets, be sure that the declared size (in bytes) of any column that receives character data is large enough to store the entire data string. For some locales, this can require up to 4 times the number of logical characters in the longest data string.

The database server handles any required code-set conversions for CLOB data. For more information, see the *Informix® GLS User's Guide*.

## Unloading Complex Types

In an UNLOAD TO file, values of complex data types appear as follows:

- Collections are introduced with the appropriate constructor (MULTISET, LIST, SET), with their comma-separated elements enclosed in braces ( {} ):
 

```
constructor{val1 , val2 , ... }
```

```
constructor{val1 , val2 , ... }
```

For example, to unload the SET values {1, 3, 4} from a column of the SET (INTEGER NOT NULL) data type, the corresponding field of the UNLOAD TO file appears as follows:

```
|SET{1 , 3 , 4}|
```

- ROW types (named and unnamed) are introduced by the ROW constructor and have their fields enclosed between parentheses and comma-separated:
 

```
ROW(val1 , val2 , ... )
```

```
ROW(val1 , val2 , ... )
```

For example, to unload the ROW values (1, 'abc'), the corresponding field of the UNLOAD TO file appears as follows:

```
|ROW(1 , abc)|
```

## DELIMITER Clause

Use the DELIMITER clause of the UNLOAD statement to specify the delimiter that separates the data contained in each column in a row in the output file.

If you omit this clause, then DB-Access checks the setting of the **DBDELIMITER** environment variable. If **DBDELIMITER** has not been set, the default delimiter is the pipe (|) symbol. You can specify the tab character `TAB (CTRL-I)` or a blank space (ASCII 32) as the delimiter symbol.

The following characters are not valid in any locale as delimiter symbols:

- Newline character (`CTRL-J`)
- Hexadecimal digits (0 to 9, a to f, A to F)
- Backslash ( \ )

The backslash ( \ ) is not a valid field separator or record delimiter because it is the default escape character, indicating that the next character is a literal character in the data, rather than a special character. However, if you change the default escape character by setting the DEFAULTESCCHAR configuration parameter or the **DEFAULTESCCHAR** session environment option, you can use a backslash as a field separator.

The following UNLOAD statement specifies the semicolon ( ; ) as the delimiter:

```
UNLOAD TO 'cust.out' DELIMITER ';'
SELECT fname, lname, company, city FROM customer;
```

## UNLOCK TABLE statement

Use the UNLOCK TABLE statement in a database that does not support transaction logging to unlock a table that you previously locked with the LOCK TABLE statement. The UNLOCK TABLE statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

#### UNLOCK TABLE

*table synonym*

| Element        | Description                   | Restrictions  | Syntax  |
|----------------|-------------------------------|---|---|
| <i>synonym</i> | Synonym for a table to unlock | The synonym and the table to which it points must exist   | <a href="#">Database Object Name on page 1450</a> |
| <i>table</i>   | Table to unlock               | Must be in a database without transaction logging, and must be a table that you previously locked | <a href="#">Database Object Name on page 1450</a> |

### Usage

**Restriction:** The UNLOCK TABLE statement is not valid within a transaction.

You can lock a table if you own the table or if you have the Select privilege on the table, either from a direct grant to your user ID or from a grant to PUBLIC. You can only unlock a table that you locked. You cannot unlock a table that another process locked. Only one lock can apply to a table at a time.

You must specify the name or synonym of the table that you are unlocking. Do not specify the name of a view, or a synonym for a view.

To change the lock mode of a table in a database that was created without transaction logging, use the UNLOCK TABLE statement to unlock the table, then issue a new LOCK TABLE statement. The following example shows how to change the lock mode of a table in a database that was created without transaction logging:

```
LOCK TABLE items IN EXCLUSIVE MODE;
...
UNLOCK TABLE items;
```

```
...  
LOCK TABLE items IN SHARE MODE;
```

The UNLOCK TABLE statement fails if it is issued within a transaction. Table locks set within a transaction are released automatically when the transaction completes.

If you are using an ANSI-compliant database, do not issue an UNLOCK TABLE statement. The UNLOCK TABLE statement fails if it is issued within a transaction, and a transaction is always in effect in an ANSI-compliant database.

460. Informix® extension

461. ESQL/C and SPL only

462. See [SET Clause on page 1042](#)463. See [WHERE Clause of UPDATE on page 1049](#)464. See [Optimizer Directives on page 1472](#)465. See [Collection-Derived Table on page 1436](#)466. See [Using the WHERE CURRENT OF Clause \(ESQL/C, SPL\) on page 1052](#)

## Usage

Use the UPDATE statement to update any of the following types of database objects or program objects:

- A row in a table: a single row, a group of rows, or all rows in a table
- An element in a column of a collection data type
- In a column of a named or unnamed ROW data type, a field or all fields.

With Informix®, you can also use this statement to change the values in one or more elements in Informix® ESQL/C or SPL collection variables or ROW variables.

For information on how to update elements of a collection variable, see [Collection-Derived Table on page 1436](#). Sections that follow in this description of the UPDATE statement describe how to update a row in a table.

You must either own the table or have the Update privilege for the table; see [GRANT statement on page 592](#). To update data in a view, you must have the Update privilege, and the view must meet the requirements that are explained in [Updating Rows Through a View on page 1040](#).

The target of the UPDATE statement cannot be a table object that the CREATE EXTERNAL TABLE statement defined.

The cursor (as defined in the SELECT ... FOR UPDATE portion of a DECLARE statement) can contain only column names. If you omit the WHERE clause, all rows of the target table are updated.

If you are using effective checking and the checking mode is set to IMMEDIATE, all enabled constraints are checked at the end of each UPDATE statement. If the checking mode is set to DEFERRED, all enabled constraints are *not* checked until the transaction is committed.

In DB-Access, if you omit the WHERE clause and are in interactive mode, DB-Access does not run the UPDATE statement until you confirm that you want to change all rows. If the statement is in a command file, however, and you are running at the command line, the statement executes immediately.

## Example

The following example creates and updates view.

```
CREATE VIEW cust_view AS SELECT * FROM customer;
UPDATE cust_view SET customer_num=10001 WHERE customer_num=101;
```

---

[RENAME SEQUENCE statement on page 716](#)

[Collection-Derived Table on page 1436](#)

[MERGE statement on page 663](#)

## Using the ONLY Keyword

If you use the UPDATE statement to update rows of a supertable, rows from its subtables can also be updated. To update rows from the supertable only, use the ONLY keyword prior to the table name, as this example shows:

```
UPDATE ONLY(am_studies_super)
WHERE advisor = "johnson"
SET advisor = "camarillo";
```

**Note:** If you use the UPDATE statement on a supertable without the ONLY keyword and without a WHERE clause, all rows of the supertable and its subtables are updated. You cannot use the ONLY keyword if you plan to use the WHERE CURRENT OF clause to update the current row of the active set of a cursor.

## Updating Rows Through a View

You can update data through a *single-table* view if you have the Update privilege on the view (see [GRANT statement on page 592](#)). For a view to be updatable, the query that defines the view must not contain any of the following items:

- Columns in the projection list that are aggregate values
- Columns in the projection list that use the UNIQUE or DISTINCT keyword
- A GROUP BY clause
- A UNION operator

In addition, if a view is built on a table that has a derived value for a column, that column cannot be updated through the view. Other columns in the view, however, can be updated. In an updatable view, you can update the values in the underlying table by inserting values into the view.

```
CREATE VIEW cust_view AS SELECT * FROM customer;
UPDATE cust_view SET customer_num=10001 WHERE customer_cum=101;
```

The following statements define a view that includes all the rows in the **customer** table and changes the **customer\_num** value to **10001** in any row where the value of that column is **101**:

```
CREATE VIEW cust_view AS SELECT * FROM customer;
UPDATE cust_view SET customer_num=10001 WHERE customer_num=101;
```

You can use data-integrity constraints to prevent users from updating values in the underlying table when the update values do not fit the SELECT statement that defined the view. For more information, see [WITH CHECK OPTION Keywords on page 457](#).

Because duplicate rows can occur in a view even if its base table has unique rows, be careful when you update a table through a view. For example, if a view is defined on the **items** table and contains only the **order\_num** and **total\_price** columns, and if two items from the same order have the same total price, the view contains duplicate rows. In this case, if you update one of the two duplicate **total\_price** values, you have no way to know which item price is updated.

**Important:** If you are using a view with a check option, you cannot update rows in a remote table.

An alternative to directly modifying data values in a view with the UPDATE statement is to create an INSTEAD OF trigger on the view. For more information, see [INSTEAD OF Triggers on Views on page 439](#).

## Updating Rows in a Database Without Transactions

If you are updating rows in a database without transactions, you must take explicit action to restore updated rows. For example, if the UPDATE statement fails after updating some rows, the successfully updated rows remain in the table. You cannot automatically recover from a failed update.

## Updating Rows in a Database with Transactions

If you are updating rows in a database with transactions, and you are using transactions, you can undo the update using the ROLLBACK WORK statement. If you do not execute a BEGIN WORK statement before the update, and the update fails, the database server automatically rolls back any database modifications that were made to the table since the beginning of the update operation.

The CREATE TEMP TABLE statement can include the WITH NO LOG option to create temporary tables that do not support transaction logging. These tables are not logged and are not recoverable.

Do not use RAW tables within a transaction. Tables that you create with the CREATE RAW TABLE statement are not logged. Thus, RAW tables are not recoverable, even if the database uses logging. RAW tables are intended for the initial loading and validation of data. After you have loaded the data, use the ALTER TABLE statement to change the table to type STANDARD, and perform a level-0 backup before you use the table in a transaction. For more information about RAW tables, refer to the *Informix® Administrator's Guide*.

In an ANSI-compliant database, transactions are implicit, and all database modifications take place within a transaction. In this case, if an UPDATE statement fails, you can use ROLLBACK WORK to undo the update.

If you are within an explicit transaction, and the update fails, the database server automatically undoes the effects of the update.

## Locking Considerations

When a row is selected with the intent to update, the update process acquires an update lock. Update locks permit other processes to read, or *share*, a row that is about to be updated, but they do not allow those processes to update or delete it.

Just before the update occurs, the update process *promotes* the shared lock to an exclusive lock. An exclusive lock prevents other processes from reading or modifying the contents of the row until the lock is released.

An update process can acquire an update lock on a row or on a page that has a shared lock from another process, but you cannot promote the update lock from shared to exclusive (and the update cannot occur) until the other process releases its lock.

If the number of rows that a single update affects is large, you can exceed the limits placed on the maximum number of simultaneous locks. If this occurs, you can reduce the number of transactions per UPDATE statement, or you can lock the page or the entire table before you execute the statement.

## Declaring an alias for the target table

You can declare an alias for the target table. The alias can reference the fully-qualified database object name of a local or remote table, view, or synonym.

The alias is a temporary name that is not registered in the system catalog of the database, and that persists only while the UPDATE statement is running.

If the name that you declare as the alias is also a keyword of the UPDATE statement, you must use the AS keyword to clarify the syntax:

```
UPDATE stock AS set
  SET unit_price = unit_price * 0.94;
```

The following UPDATE statement references the qualified name of a table in the target clause and in two subqueries:

```
UPDATE nmosdb@wnmserver1:test
  SET name=(SELECT name FROM test
            WHERE test.id = nmosdb@wnmserver1:test.id)
  WHERE EXISTS(
    SELECT 1 FROM test WHERE test.id = nmosdb@wnmserver1:test.id
  );
```

The next UPDATE statement is logically equivalent to the previous example, but declares **r\_t** an alias for the qualified table name:

```
UPDATE nmosdb@wnmserver1:test r_t
  SET name=(SELECT name FROM test
            WHERE test.id = r_t.id)
  WHERE EXISTS(
    SELECT 1 FROM test WHERE test.id = r_t.id
  );
```

Declaring the table alias simplifies the notation of the second example above.

## SET Clause

Use the SET clause to identify the columns to be updated and assign values to each column.

The SET clause supports the following syntax formats:

- A single-column format, which pairs each column with a single expression
- A multiple-column format, which associates a list of multiple columns with the values returned by one or more expressions

SET Clause

## SET

Single-Column Format <sup>468</sup>  
467

Multiple-Column Format<sup>469</sup>

### Example

The following UPDATE statement uses the single-column format of the SET clause to change the value of the **customer.city** column of any existing row whose value in the **customer.customer\_num** column is 103.

```
UPDATE customer
  SET city = 'Alviso'
 WHERE customer_num = 103;
```

If no row has 103 as its **customer\_num** column value, this example has no effect on the **customer** table.

## Single-Column Format

Use the single-column format to pair one column with a single expression.

Single-Column Format

, *column* =

*expression*

(*singleton\_select*)

**NULL**

*collection\_var*

| Element                 | Description                           | Restrictions   | Syntax                                       |
|-------------------------|---------------------------------------|--|--|
| <i>column</i>           | Column to be updated                  | Cannot be a serial data type   | <a href="#">Identifier on page 1456</a>      |
| <i>collection_var</i>   | Host or program variable              | Must be declared as a collection data type   | Language specific                            |
| <i>expression</i>       | Returns a value for <i>column</i>     | Cannot contain aggregate functions   | <a href="#">Expression on page 1193</a>      |
| <i>singleton_select</i> | Subquery that returns exactly one row | Returned subquery values must have a 1-to-1 correspondence with <i>column</i> list | <a href="#">SELECT statement on page 768</a> |

467. Informix® extension

468. See [Single-Column Format on page 1043](#)

469. See [Multiple-Column Format on page 1045](#)

You can use this syntax to update a column that has a ROW data type.

You can include any number of "single *column* = single *expression*" terms. The *expression* can be an SQL subquery (enclosed between parentheses) that returns a single row, provided that the corresponding *column* is of a data type that can store the value (or the set of values) from the row that the subquery returns.

To specify values of a ROW-type column in a SET clause, see [Updating ROW-Type Columns on page 1046](#). The following examples illustrate the single-column format of the SET clause.

```
UPDATE customer
  SET address1 = '1111 Alder Court', city = 'Palo Alto',
      zipcode = '94301' WHERE customer_num = 103;

UPDATE stock
  SET unit_price = unit_price * 1.07;
```

## Using a Subquery to Update a Single Column

You can update the column specified in the SET clause with the value that a subquery returns.

```
UPDATE orders
  SET ship_charge =
    (SELECT SUM(total_price) * .07 FROM items
     WHERE orders.order_num = items.order_num)
  WHERE orders.order_num = 1001;
```

If you are updating a supertable in a table hierarchy, the SET clause cannot include a subquery that references a subtable.

If you are updating a subtable in a table hierarchy, a subquery in the SET clause can reference the supertable if it references only the supertable. That is, the subquery must use the SELECT FROM ONLY (*supertable*) syntax.

## Updating a Column to NULL

Use the NULL keyword to modify a column value when you use the UPDATE statement. For example, for a customer whose previous address required two address lines but now requires only one, you would use the following entry:

```
UPDATE customer
  SET address1 = '123 New Street',
      address2 = null,
      city = 'Palo Alto',
      zipcode = '94303'
  WHERE customer_num = 134;
```

## Updating the Same Column Twice

You can specify the same column more than once in the SET clause. If you do so, the column is set to the last value that you specified for the column. In the next example, the **fname** column appears twice in the SET clause. For the row where the customer number is 101, the user sets **fname** first to *gary* and then to *harry*. After the UPDATE statement executes, the value of **fname** is *harry*.

```
UPDATE customer
  SET fname = "gary", fname = "harry"
  WHERE customer_num = 101;
```

## Multiple-Column Format

Use the multiple-column format of the SET clause to list multiple columns and set them equal to corresponding expressions.

### Multiple-Column Format

```
(
, column
)
*
=
(
, expression
, (singleton_select)
NULL
)
```

| Element                 | Description   | Restrictions   | Syntax                                       |
|-------------------------|---|--|--|
| <i>column</i>           | Name of a column to be updated                      | Cannot have a serial or ROW type. The number of <i>column</i> names must equal the number of values returned to the right of the = sign. | <a href="#">Identifier on page 1456</a>      |
| <i>expression</i>       | Expression that returns a value for a <i>column</i> | Cannot include aggregate functions   | <a href="#">Expression on page 1193</a>      |
| <i>singleton_select</i> | Subquery that returns exactly one row               | Values that the subquery returns must correspond to columns in the <i>column</i> list  | <a href="#">SELECT statement on page 768</a> |
| <i>SPL function</i>     | SPL routine that returns one or more values         | Returned values must have a 1-to-1 correspondence to columns in the <i>column</i> list   | <a href="#">Identifier on page 1456</a>      |

The multiple-column format of the SET clause offers the following options for listing a set of columns that you intend to update:

- Explicitly list each column, placing commas between columns and enclosing the set of columns between parentheses.
- Implicitly list all columns in the table by using an asterisk (\*).

470. See [Arguments on page 1433](#)

You must list each expression explicitly, placing comma ( , ) separators between expressions and enclosing the set of expressions between parentheses. The number of columns must equal the number of values returned by the expression list, unless the expression list includes an SQL subquery.

The following examples show the multiple-column format of the SET clause:

```
UPDATE customer
  SET (fname, lname) = ('John', 'Doe') WHERE customer_num = 101;

UPDATE manufact
  SET * = ('HNT', 'Hunter') WHERE manu_code = 'ANZ';
```

## Using a Subquery to Update Multiple Column Values

The expression list can include one or more subqueries. Each must return a single row containing one or more values. The number of columns that the SET clause explicitly or implicitly specifies must equal the number of values returned by the expression (or expression list) that follows the equal ( = ) sign in the multiple-column SET clause.

The subquery must be enclosed between parentheses. These parentheses are nested within the parentheses that immediately follow the equal ( = ) sign. If the expression list includes multiple subqueries, each subquery must be enclosed between parentheses, with a comma ( , ) separating successive subqueries:

```
UPDATE ... SET ... = ((subqueryA),(subqueryB), ... (subqueryN))
```

The following examples show the use of subqueries in the SET clause:

```
UPDATE items
  SET (stock_num, manu_code, quantity) =
    ( (SELECT stock_num, manu_code FROM stock
      WHERE description = 'baseball'), 2)
  WHERE item_num = 1 AND order_num = 1001;

UPDATE table1
  SET (col1, col2, col3) =
    ((SELECT MIN (ship_charge), MAX (ship_charge) FROM orders), '07/01/2007')
  WHERE col4 = 1001;
```

If you are updating a supertable in a table hierarchy, the SET clause cannot include a subquery that references one of its subtables. If you are updating a subtable in a table hierarchy, a subquery in the SET clause can reference the supertable if it references only the supertable. That is, the subquery must use the SELECT FROM ONLY (*supertable*) syntax.

## Updating ROW-Type Columns

Use the SET clause to update a named or unnamed ROW-type column. For example, suppose you define the following named ROW type and a table that contains columns of both named and unnamed ROW types:

```
CREATE ROW TYPE address_t
(
  street CHAR(20), city CHAR(15), state CHAR(2)
```

```
);
CREATE TABLE empinfo
(
  emp_id INT
  name ROW ( fname CHAR(20), lname CHAR(20)),
  address address_t
);
```

To update an unnamed ROW type, specify the ROW constructor before the parenthesized list of field values.

The following statement updates the **name** column (an unnamed ROW type) of the **empinfo** table:

```
UPDATE empinfo SET name = ROW('John','Williams') WHERE emp_id =455;
```

To update a named ROW type, specify the ROW constructor before the list (in parentheses) of field values, and use the cast (::) operator to cast the ROW value as a named ROW type. The following statement updates the **address** column (a named ROW type) of the **empinfo** table:

```
UPDATE empinfo
SET address = ROW('103 Baker St','Tracy','CA')::address_t
WHERE emp_id = 3568;
```

For more information on the syntax for ROW constructors, see [Constructor Expressions on page 1247](#). See also [Literal Row on page 1421](#).

The ROW-column SET clause can only support literal values for fields. To use an ESQL/C variable to specify a field value, you must select the ROW data into a **row** variable, use host variables for the individual field values, then update the ROW column with the **row** variable. For more information, see [Updating a Row Variable \(ESQL/C\) on page 1053](#).

You can use Informix® ESQL/C host variables to insert *non-literal* values as:

- An entire row type into a column
  - Use a **row** variable as a variable name in the SET clause to update all fields in a ROW column at one time.
- Individual fields of a ROW type
  - To insert non-literal values into a ROW-type column, you can first update the elements in a **row** variable and then specify the **collection** variable in the SET clause of an UPDATE statement.

When you use a **row** variable in the SET clause, the **row** variable must contain values for each field value. For information on how to insert values into a **row** variable, see [Updating a Row Variable \(ESQL/C\) on page 1053](#).

You can use the UPDATE statement to modify only some of the fields in a row:

- Specify the field names with field projection for all fields whose values remain unchanged.

For example, the following UPDATE statement changes only the **street** and **city** fields of the **address** column of the **empinfo** table:

```
UPDATE empinfo
SET address = ROW('23 Elm St', 'Sacramento', address.state)
WHERE emp_id = 433;
```

The **address.state** field remains unchanged.

- Select the row into an ESQL/C **row** variable and update the desired fields.

For more information, see [Updating a Row Variable \(ESQL/C\) on page 1053](#).

## Updating Collection Columns

You can use the SET clause to update values in a collection column. For more information, see [Collection Constructors on page 1248](#).

A collection variable can update a collection-type column. With a collection variable, you can insert one or more individual elements of a collection. For more information, see [Collection-Derived Table on page 1436](#).

For example, suppose you define the **tab1** table as follows:

```
CREATE TABLE tab1
(
  int1 INTEGER,
  list1 LIST(ROW(a INTEGER, b CHAR(5)) NOT NULL),
  dec1 DECIMAL(5,2)
);
```

The following UPDATE statement updates a row in **tab1**:

```
UPDATE tab1
SET list1 = LIST(ROW(2, 'zyxwv'),
  ROW(POW(2,6), '=64'),
  ROW(ROUND(ROOT(146)), '=12')),
WHERE int1 = 10;
```

Collection column **list1** in this example has three elements. Each element is an unnamed ROW type with an INTEGER field and a CHAR(5) field. The first element includes two literal values: an integer ( `2` ) and a quoted string ( `'zyxwv'` ).

The second and third elements also use a quoted string to indicate the value for the second field. They each designate the value for the first field with an expression, however, rather than with a literal value.

## Updating Values in Opaque-Type Columns

Some opaque data types require special processing when they are updated. For example, if an opaque data type contains spatial or multirepresentational data, it might provide a choice of how to store the data: inside the internal structure or, for large objects, in a smart large object.

This processing is accomplished by calling a user-defined support function called **assign()**. When you execute UPDATE on a table whose rows contain one of these opaque types, the database server automatically invokes the **assign()** function for the type. This function can make the decision of how to store the data. For more information about the **assign()** support function, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

## Data Types in Distributed UPDATE Operations

Distributed UPDATE operations across tables in databases of different server instances can return only a subset of the data types that distributed UPDATE operations can return from tables that are all in databases of the same Informix® instance.

The UPDATE statement (or any other SQL data-manipulation language statement) that accesses a database of another Informix® instance can reference only the following data types:

- Built-in data types that are not opaque or complex
- BOOLEAN
- BSON
- JSON
- LVARCHAR
- DISTINCT of built-in types that are not opaque
- DISTINCT of BOOLEAN
- DISTINCT of BSON
- DISTINCT of JSON
- DISTINCT of LVARCHAR
- DISTINCT of the DISTINCT types in this list.

Cross-server distributed UPDATE operations can support these DISTINCT types only if the DISTINCT types are cast explicitly to built-in types, and all of the DISTINCT types, their data type hierarchies, and their casts are defined exactly the same way in each participating database. For additional information about the data types that Informix® supports in cross-server DML operations, see [Data Types in Cross-Server Transactions on page 781](#).

Cross-database distributed UPDATE operations that access other databases of the local Informix® instance, however, can access the cross-server data types in the preceding list, and also the following data types:

- Most of the *built-in opaque data types*, as listed in [Data Types in Cross-Database Transactions on page 779](#)
- DISTINCT of the built-in types that are referenced in the preceding line
- DISTINCT of any of the data types that are listed in either of the two preceding lines
- Opaque user-defined data types (UDTs) that are explicitly cast to built-in data types.

Cross-database UPDATE operations can support these DISTINCT types and opaque UDTs only if all the opaque UDTs and DISTINCT types are cast explicitly to built-in types, and all of the opaque UDTs, DISTINCT types, data type hierarchies, and casts are defined exactly the same way in each of the participating databases.

Distributed UPDATE transactions cannot access the database of another Informix® instance unless both servers define TCP/IP or IPCSTR connections in their DBSERVERNAME or DBSERVERALIASES configuration parameters and in the **sqlhosts** file or SQLHOSTS registry subkey. The requirement, that both participating servers support the same type of connection (either TCP/IP or else IPCSTR), applies to any communication between Informix® instances, even if both reside on the same computer.

## WHERE Clause of UPDATE

The WHERE clause lets you specify search criteria to limit the rows to be updated. If you omit the WHERE clause, every row in the table is updated. For more information, see the [WHERE clause of SELECT on page 813](#).

## SQLSTATE Values When Updating an ANSI-Compliant Database

If you update a table in an ANSI-compliant database with an UPDATE statement that contains the WHERE clause and no rows are found, the database server issues a warning.

You can detect this warning condition in either of the following ways:

- The GET DIAGNOSTICS statement sets the **RETURNED\_SQLSTATE** field to the value `02000`. In an SQL API application, the **SQLSTATE** variable contains this same value.
- In an SQL API application, the **sqlca.sqlcode** and **SQLCODE** variables contain the value `100`.

The database server also sets **SQLSTATE** and **SQLCODE** to these values if the UPDATE ... WHERE statement is part of a multistatement PREPARE and the database server returns no rows.

## SQLSTATE Values When Updating a Non-ANSI Database

In a database that is not ANSI compliant, the database server does not return a warning when it finds no matching rows for the WHERE clause of an UPDATE statement. The **SQLSTATE** code is `00000` and the **SQLCODE** code is zero (0). If the UPDATE ... WHERE statement is part of a multistatement PREPARE, however, and no rows are returned, the database server issues a warning, and sets **SQLSTATE** to `02000` and sets **SQLCODE** to `100`.

Client-server communication protocols of Informix®, such as SQLI and DRDA®, support **SQLSTATE** code values. For a list of these codes, and for information about how to get the message text, see [Using the SQLSTATE Error Status Code on page 582](#).

## Subqueries in the WHERE Clause of UPDATE

The FROM clause of a subquery in the WHERE clause of the UPDATE statement can specify as a data source the same table or view that the Table Options clause of the UPDATE statement specifies. UPDATE operations with subqueries that reference the same table object are supported only if all of the following conditions are true:

- The subquery either returns a single row, or else has no correlated column references.
- The subquery is in the UPDATE statement WHERE clause, using Condition with Subquery syntax.
- No SPL routine in the subquery can reference the same table that UPDATE is modifying.

Unless all of these conditions are satisfied, UPDATE statements that include subqueries that reference the same table or view that the UPDATE statement modifies return error -360.

The following example updates the **stock** table by reducing the **unit\_price** value by 5% for a subset of prices. The WHERE clause specifies which prices to reduce by applying the IN operator to the rows returned by a subquery that selects only the rows of the **stock** table where the **unit\_price** value is greater than 50:

```
UPDATE stock SET unit_price = unit_price * 0.95
WHERE unit_price IN
  (SELECT unit_price FROM stock WHERE unit_price > 50);
```

This subquery includes only uncorrelated column references, because its only referenced column is in a table specified in its FROM clause. The requirements listed above are in effect, because the data source of the subquery is the same **stock** table that the Table Options clause of the outer UPDATE statement specifies.

The previous example produces the same results as issuing two separate DML statements:

- The SELECT statement, to return a temporary table, **tmp1**, that contains the same rows from the **stock** table that the subquery returned.
- The UPDATE statement, to issue a subquery of the temporary table as a predicate in its WHERE clause to modify every row of the **stock** table where the **unit\_price** matches a value in the temporary table:

```
SELECT unit_price FROM stock WHERE unit_price > 50 INTO TEMP tmp1;
UPDATE stock SET unit_price = unit_price * 0.95
WHERE unit_price IN ( SELECT * FROM tmp1 );
```

Here is an example of a more complex UPDATE statement that includes multiple uncorrelated subqueries in its WHERE clause:

```
UPDATE t1 SET a = a + 10
WHERE a > ALL (SELECT a FROM t1 WHERE a > 1) AND
      a > ANY (SELECT a FROM t1 WHERE a > 10) AND
      EXISTS (SELECT a FROM t1 WHERE a > 5);;
```

If an enabled Select trigger is defined on a table that is the data source of a subquery in the WHERE clause of an UPDATE statement that modifies the same table, executing that subquery within the UPDATE statement does not activate the Select trigger. Consider the following program fragment:

```
CREATE TRIGGER sel_t11 SELECT ON t1 BEFORE
  (UPDATE d1
   SET (c1, c2, c3, c4, c5) =
       (c1 + 1, c2 + 1, c3 + 1, c4 + 1, c5 + 1));

UPDATE t2 SET c1 = c1 + 1
WHERE c1 IN
  (SELECT t1.c1 from t1 WHERE t1.c1 > 10 );
```

In the example above, trigger **sel\_t11** is not activated as part of the UPDATE operation on table **t2**.

A subquery in the WHERE clause of the UPDATE statement can include the UNION or the UNION ALL operator, as in the following example.

```
UPDATE t1 SET a = a + 10 WHERE a in (SELECT a FROM t1 WHERE a > 1
  UNION SELECT a FROM t1, t2 WHERE a < b);
```

If the table that the outer UPDATE statement modifies a typed table within a table hierarchy, Informix® supports all of the following operations that use valid subqueries in the WHERE clause of UPDATE:

- UPDATE on target parent table with subquery ( SELECT from parent table )
- UPDATE on target parent table with subquery ( SELECT from child table )

- UPDATE on target child table with subquery ( SELECT from parent table )
- UPDATE on target child table with subquery ( SELECT from child table ).

The following program fragment illustrates UPDATE operations with subqueries on typed tables:

```
CREATE ROW TYPE r1 (c1 INT, c2 INT);
CREATE ROW TYPE r2 UNDER r1;
CREATE TABLE t1 OF TYPE r1; -- parent table
CREATE TABLE t2 OF TYPE r2 UNDER t1; -- child table

UPDATE t1 SET c1 = c1 + 1 WHERE c1 IN
  ( SELECT t1.c1 FROM t1 WHERE t1.c1 > 10);

UPDATE t1 SET c1 = c1 + 1 WHERE c1 IN
  ( SELECT t2.c1 FROM t2 WHERE t2.c1 > 10);

UPDATE t2 SET c1 = c1 + 1 WHERE c1 IN
  ( SELECT t2.c1 FROM t2 WHERE t2.c1 > 10);

UPDATE t2 SET c1 = c1 + 1 WHERE c1 IN
  ( SELECT t1.c1 FROM t1 WHERE t1.c1 > 10);
```

See the [Condition with Subquery on page 1158](#) topic for more information about how to use subqueries that return multiple rows as predicates in the WHERE clause of the UPDATE statement.

## Using the WHERE CURRENT OF Clause (ESQL/C, SPL)

Use the WHERE CURRENT OF clause to update the current row of a cursor that was declared FOR UPDATE, or to update the current element of a Collection cursor.

Here the *cursor* name cannot be specified as a host variable.

The current row is the most recently fetched row. Because the UPDATE statement does not advance the cursor to the next row, the current row position within the active set of the cursor is not changed by this operation.

For table hierarchies of Informix®, you cannot use this clause if you are selecting from only one table in a table hierarchy. That is, you cannot use this option if you use the ONLY keyword.

In ESQL/C routines, to include the WHERE CURRENT OF keywords, you must have previously used the DECLARE statement to define the *cursor* with the FOR UPDATE option. If the DECLARE statement that created the cursor specified one or more columns in the FOR UPDATE clause, you are restricted to updating only those columns in a subsequent UPDATE ... WHERE CURRENT OF statement. The advantage to specifying columns in the FOR UPDATE clause of a DECLARE statement is speed. The database server can usually perform updates more quickly if columns are specified in the DECLARE statement.

In SPL routines, you can specify a cursor after the WHERE CURRENT OF keywords in an UPDATE statement only if you declared the *cursor\_id* in the FOREACH statement of SPL. You cannot use the DECLARE statement in an SPL routine to declare the name of a dynamic cursor and to associate that cursor with the statement identifier of a prepared object that the PREPARE statement has declared in the same SPL routine.

**Note:** An Update cursor can perform updates that are not possible with the UPDATE statement.

The following Informix® ESQL/C example illustrates the CURRENT OF form of the WHERE clause. In this example, updates are performed on a range of customers who receive 10-percent discounts (assume that a new column, **discount**, is added to the **customer** table). The UPDATE statement is prepared outside the WHILE loop to ensure that parsing is done only once.

```
char answer [1] = 'y';
EXEC SQL BEGIN DECLARE SECTION;
  char fname[32],lname[32];
  int low,high;
EXEC SQL END DECLARE SECTION;
main()
{
  EXEC SQL connect to 'stores_demo';
  EXEC SQL prepare sel_stmt from
    'select fname, lname from customer
     where cust_num between ? and ? for update';

  EXEC SQL declare x cursor for sel_stmt;
  printf("\nEnter lower limit customer number: ");
  scanf("%d", &low);
  printf("\nEnter upper limit customer number: ");
  scanf("%d", &high);
  EXEC SQL open x using :low, :high;
  EXEC SQL prepare u from
    'update customer set discount = 0.1 where current of x';
  while (1)
  {
    EXEC SQL fetch x into :fname, :lname;
    if ( SQLCODE == SQLNOTFOUND) break;
  }
  printf("\nUpdate %.10s %.10s (y/n)?", fname, lname);
  if (answer = getch() == 'y')
    EXEC SQL execute u;
  EXEC SQL close x;
}
```

## Updating a Row Variable (ESQL/C)

### About this task

The UPDATE statement with the Collection-Derived Table segment allows you to update fields in a **row** variable. The Collection-Derived Table segment identifies the **row** variable in which to update the fields. For more information, see [Collection-Derived Table on page 1436](#).

To update fields

1. Create a **row** variable in your Informix® ESQL/C program.
2. Optionally, select a ROW-type column into the **row** variable with the SELECT statement (without the Collection-Derived Table segment).

3. Update fields of the **row** variable with the UPDATE statement and the Collection-Derived Table segment.
4. After the **row** variable contains the correct fields, you then use the UPDATE or INSERT statement on a table or view name to save the **row** variable in the ROW column (named or unnamed).

## Results

The UPDATE statement and the Collection-Derived Table segment allow you to update a field or a group of fields in the **row** variable. Specify the new field values in the SET clause. For example, the following UPDATE changes the **x** and **y** fields in the **myrect** Informix® ESQL/C **row** variable:

```
EXEC SQL BEGIN DECLARE SECTION;
    row (x int, y int, length float, width float) myrect;
EXEC SQL END DECLARE SECTION;
. . .
EXEC SQL select into :myrect from rectangles where area = 64;
EXEC SQL update table(:myrect) set x=3, y=4;
```

Suppose that after the SELECT statement, the **myrect2** variable has the values **x=0**, **y=0**, **length=8**, and **width=8**. After the UPDATE statement, the **myrect2** variable has field values of **x=3**, **y=4**, **length=8**, and **width=8**. You cannot use a **row** variable in the Collection-Derived Table segment of an INSERT statement.

You can, however, use the UPDATE statement and the Collection-Derived Table segment to insert new field values into a **row** host variable, if you specify a value for every field in the row.

For example, the following code fragment inserts new field values into the **row** variable **myrect** and then inserts this **row** variable into the database:

```
EXEC SQL update table(:myrect)
    set x=3, y=4, length=12, width=6;
EXEC SQL insert into rectangles
    values (72, :myrect);
```

If the **row** variable is an untyped variable, you must use a SELECT statement *before* the UPDATE so that Informix® ESQL/C can determine the data types of the fields. An UPDATE of fields in a **row** variable cannot include a WHERE clause.

The **row** variable can store the field values of the row, but it has no intrinsic connection with a database column. Once the **row** variable contains the correct field values, you must then save the variable into the ROW column with one of the following SQL statements:

- To update the ROW column in the table with contents of the **row** variable, use an UPDATE statement on a table or view name and specify the **row** variable in the SET clause. (For more information, see [Updating ROW-Type Columns on page 1046](#).)
- To insert a **row** into a column, use the INSERT statement on a table or view name and specify the **row** variable in the VALUES clause. (For more information, see [Inserting Values into ROW-Type Columns on page 647](#).)

For examples of SPL ROW variables, see the *Informix® Guide to SQL: Tutorial*. For more information on using Informix® ESQL/C **row** variables, see the discussion of complex data types in the *Informix® ESQL/C Programmer's Manual*.

## UPDATE STATISTICS statement

Use the UPDATE STATISTICS statement to update system catalog information that the query optimizer uses for operations on objects in the local database. The UPDATE STATISTICS statement is an extension to the ANSI/ISO standard for SQL.

### Syntax

#### UPDATE STATISTICS

#### LOW

Table and Column Scope

#### DROP DISTRIBUTIONS

#### ONLY

#### MEDIUM HIGH

Table and Column Scope

Resolution Clause <sup>471</sup>

#### FORCE AUTO

Routine Statistics <sup>472</sup>

Table and Column Scope

#### FOR TABLE

'owner' .

*table synonym*

(

, *column*

)

#### ONLY (

'owner' .

*table synonym*

)

(

, *column*

)

| Element        | Description  | Restrictions  | Syntax                                  |
|----------------|--|---|---|
| <i>column</i>  | A column in table or synonym                             | Must exist. With the MEDIUM or HIGH keyword, the column cannot be of BYTE, LVARCHAR, or TEXT data type. | <a href="#">Identifier on page 1456</a> |
| <i>owner</i>   | The owner of table or synonym                            | Must be the owner of table or synonym   | <a href="#">Owner name on page 1488</a> |
| <i>synonym</i> | A synonym for a table whose statistics are to be updated | The synonym and the table to which it points must exist in the current database                         | <a href="#">Identifier on page 1456</a> |

471. See [Resolution Clause on page 1065](#)

472. See [Routine Statistics on page 1068](#)

| Element      | Description                                  | Restrictions  | Syntax                                  |
|--------------|--|---|---|
| <i>table</i> | Table for which statistics are to be updated | Must exist in the current database or be a temporary table created in the current session | <a href="#">Identifier on page 1456</a> |

## Usage

Use the UPDATE STATISTICS statement to perform any of the following tasks:

- Calculate the distribution of column values for tables and table fragments.
- Update system catalog tables that the database server uses to optimize queries.
- Force reoptimization of SPL routines.
- Convert existing indexes when you upgrade the database server.

Run the UPDATE STATISTICS statement in a transaction that does not contain any other statements.

The Table and Column Scope clause and the Routine Statistics clause can be empty. If you specify no mode, no table, no routine, and no Resolution clause, the default scope of the UPDATE STATISTICS statement is all the permanent tables in the current database, as in the following example.

```
UPDATE STATISTICS; -- calculates LOW column distribution statistics for
                  -- all permanent user-defined and system catalog tables
                  -- that the AUTO_STAT_MODE and STATCHANGE settings allow
```

For more examples of UPDATE STATISTICS statements that specify no identifiers of tables or of SPL routines, see the topic [The scope of UPDATE STATISTICS statements on page 1057](#). See also the references to AUTO\_STAT\_MODE and STATCHANGE topics in [Performance considerations of UPDATE STATISTICS statements on page 1072](#).

The UPDATE STATISTICS statement is not supported on secondary servers within a high-availability cluster.

**Restriction:** You cannot update the statistics for a table or update the query plan of a UDR in any database except the current database. That is, the database server ignores remote database objects when executing the UPDATE STATISTICS statement.

**Important:** The statistics that the database server collects might require an sbspace for storage. You can create an sbspace by running the onspaces -c -S command. You must also set the SYSSBSPACENAME configuration parameter to the sbspace name. If the SYSSBSPACENAME configuration parameter is not set, the database server might not be able to store the column distribution statistics, so that the UPDATE STATISTICS statement fails with error -9814, "Invalid default sbspace name".

## The scope of UPDATE STATISTICS statements

The scope of UPDATE STATISTICS can be restricted by whatever identifiers of tables or columns follow the `FOR TABLE` keywords, or by whatever identifiers of SPL routines follow the `FOR FUNCTION`, `FOR PROCEDURE`, or `FOR ROUTINE` keywords.

### Scope of UPDATE STATISTICS for tables

The specifications that follow the STATISTICS keyword determine the scope of UPDATE STATISTICS statements.

- If the UPDATE STATISTICS statement includes no `FOR` keyword, then the scope cannot be explicitly restricted to a single table or to a single SPL routine.

In the case of no syntax tokens following the `STATISTICS` keyword, the default scope is to update statistics in `LOW` mode for every permanent table in the current database, including its system catalog tables, and to update the statistics in the **sysables**, **syscolumns**, and **sysindices** system catalog tables.

Both of the following examples produce the same result:

```
UPDATE STATISTICS;
UPDATE STATISTICS LOW;
```

For database tables with distributed storage, the CREATE TABLE or ALTER TABLE statement that defined the Statistics Options properties of the table determines the table-level or fragment-level granularity of these distribution statistics.

If you include only the `MEDIUM` or `HIGH` keyword, the scope is the same, although the resources required for the operation are greater.

- If you include only the `FOR TABLE` keywords without also specifying the name or synonym of a table, the database server recalculates distributions on all of the tables in the current database, and on all of the temporary tables in your session. UPDATE STATISTICS has no effect, however, on objects defined by the CREATE EXTERNAL TABLE statement.
- If you specify a table after the `FOR TABLE` keywords without also specifying a list of columns, the database server recalculates the statistical distributions on all of the columns of the specified table.
- If you specify a table after the `FOR TABLE` keywords and a list of columns, the database server recalculates the statistical distributions of only the specified columns.

In summary, for UPDATE STATISTICS statements that include no database object names, the database server updates distribution statistics on the following table objects by default:

- If you specify no scope or mode,

```
UPDATE STATISTICS;
```

distribution statistics are calculated in `LOW` mode for all permanent tables in the database.

- If you specify the scope as `FOR TABLE`, but with no list of tables,

```
UPDATE STATISTICS MEDIUM FOR TABLE;
```

distribution statistics are calculated in the specified mode for all permanent tables in the database and for all temporary tables in the session. In the example above, `MEDIUM` specifies a more costly statistics mode than the default `LOW` mode, but has no effect on which table objects are in scope.

### The scope of UPDATE STATISTICS for SPL routines

For `UPDATE STATISTICS` statements that include the `FOR FUNCTION`, `FOR PROCEDURE`, or `FOR ROUTINE` keywords, the scope depends on whether you also include the name of a routine and an argument list.

- If you specify the scope as `FOR PROCEDURE`, or `FOR ROUTINE`, or `FOR FUNCTION`, but with no list of SPL routines, as in these examples,

```
UPDATE STATISTICS FOR FUNCTION;
UPDATE STATISTICS FOR PROCEDURE;
UPDATE STATISTICS FOR ROUTINE;
```

the database server takes these actions:

- reoptimizes the execution plans for the DML statements in every SPL routine in the database,
- and updates the **sysprocplan** system catalog table with the reoptimized execution plan.

It does not, however, refresh any table distribution statistics.

### The scope for overloaded SPL routines

An `UPDATE STATISTICS` statement that specifies the identifier of an overloaded SPL routine identifier, where more than one routine have the same name, but different parameters, can reoptimize more than one SPL routine.

- If you specify the scope with the name of an SPL routine, but with no list of parameters,

```
UPDATE STATISTICS FOR FUNCTION someSPLroutine;
UPDATE STATISTICS FOR PROCEDURE someSPLroutine;
UPDATE STATISTICS FOR ROUTINE someSPLroutine;
```

the execution plans are reoptimized for the DML statements in any SPL routine with the specified identifier in the database. If the routine name is overloaded, because more than one SPL routine is registered in the database with that name, every SPL routine with that name is reoptimized.

- If you specify the scope with the name of an overloaded SPL routine and a parameter list,

```
UPDATE STATISTICS FOR FUNCTION someSPLroutine(INT, CHAR(140));
UPDATE STATISTICS FOR PROCEDURE someSPLroutine(INT, CHAR(140));
UPDATE STATISTICS FOR ROUTINE someSPLroutine(INT, CHAR(140));
```

the execution plans are reoptimized for the DML statements in any SPL routine with the specified identifier and the same argument types in the database.

If the name of an SPL routine is not overloaded, however, you can omit the parameter list and use the `SPECIFIC` keyword to restrict the scope of the `UPDATE STATISTICS` statement to the specified SPL routine:

```
UPDATE STATISTICS FOR SPECIFIC FUNCTION someSPLroutine;
UPDATE STATISTICS FOR SPECIFIC PROCEDURE someSPLroutine;
UPDATE STATISTICS FOR SPECIFIC ROUTINE someSPLroutine;
```

No other routine will be reoptimized, if the specified name is unique among SPL routine names in the database.

### Restricting the scope for tables with automatic mode

When the automatic mode of UPDATE STATISTICS is enabled for the database or for only the current session, the default scope of UPDATE STATISTICS can be further reduced to tables and table fragments with stale distribution statistics. Only these are refreshed, if the percentage of rows that subsequent DML operations have changed exceeds a user-defined STATCHANGE threshold. This restriction can apply to the database, to the session, or to individual tables, if you set their thresholds in the Statistics Options clause of CREATE TABLE or ALTER TABLE statements.

For example, if the AUTO\_STAT\_MODE setting is ON for the session, and one or more tables that the Perform\_work function processed have a high STATCHANGE threshold, you might decide to override the selective refreshing of table statistics by including the `FORCE` keyword:

```
UPDATE STATISTICS FOR SPECIFIC FUNCTION Perform_work FORCE;
```

This overrides the restriction to tables with stale statistics, so that the execution plan for Perform\_work will be based on the current data values, whether or not the column distribution statistics in the system catalog satisfy the STATCHANGE criteria for stale data,

For more information about automating the selective recalculation of distribution statistics, see the [STATCHANGE session environment option on page 952](#) and [AUTO\\_STAT\\_MODE session environment option on page 912](#) topics.

For information about the performance advantages of restricting the scope of UPDATE STATISTICS statements, see [Performance considerations of UPDATE STATISTICS statements on page 1072](#).

## Updating Statistics for Columns of User-Defined Types

To calculate statistics for a column of a user-defined data type (UDT), you must use either the UPDATE STATISTICS MEDIUM FOR TABLE or the UPDATE STATISTICS HIGH FOR TABLE statement.

Without the `MEDIUM` or `HIGH` keyword, the UPDATE STATISTICS FOR TABLE statement ignores UDT columns.

### Restrictions on UDT statistics

The UPDATE STATISTICS statement does not collect values for the `colmin` and `colmax` columns of the `syscolumns` system catalog table for columns that hold user-defined data types.

To drop distribution statistics for columns that store values of user-defined data types, you must execute UPDATE STATISTICS in LOW mode and include the `DROP DISTRIBUTIONS` keywords.

When you run the UPDATE STATISTICS LOW FOR TABLE DROP DISTRIBUTIONS statement, the database server deletes the row in the `sysdistrib` system catalog table that corresponds to the `tableid` and `colno` values for the column. In addition, the database server removes any large objects that might have been created to store distribution statistics for the specified opaque column.

## Requirements for Statistics on Opaque Columns

UPDATE STATISTICS can collect statistics for columns of user-defined opaque data types only if support routines for **statcollect( )**, **statprint( )**, and the selectivity functions are defined for the UDTs. You must also hold Usage privilege on these routines.

In some cases, UPDATE STATISTICS also requires an sbspace as specified by the SYSSBSPACENAME configuration parameter. For information about how to provide statistical data for a column whose data type is a UDT, refer to the *Informix® DataBlade® API Programmer's Guide*. For information about SYSSBSPACENAME, refer to your .

---

## Using the FORCE and AUTO keywords

In sessions or in databases where the automatic UPDATE STATISTICS mode is enabled, you can optionally use either the **FORCE** keyword or the **AUTO** keyword to control the scope of the UPDATE STATISTICS statement when it updates the current distribution statistics of tables and columns in the system catalog. These keywords affect only table and fragment statistics, and are not valid in operations on SPL routine statistics.

If you omit both the **FORCE** keyword and the **AUTO** keyword, the effect of the UPDATE STATISTICS statement on table and fragment distribution statistics is determined by the explicit or default setting of the AUTO\_STAT\_MODE configuration parameter, unless the AUTO\_STAT\_MODE session environment variable is set to override that configuration parameter for the current session.

Specifying either of the **FORCE** or **AUTO** keywords affects only the current UPDATE STATISTICS operation. The database server issues an exception if you attempt to include both the **FORCE** and the **AUTO** keywords in the same UPDATE STATISTICS statement.

### The FORCE keyword

The **FORCE** keyword refreshes the statistics for all tables and columns within the specified scope. If automatic mode for the UPDATE STATISTICS statement is enabled, the **FORCE** keyword overrides automatic mode, so that values of the STATCHANGE attributes of tables and fragments within the scope of the FOR TABLE specification are ignored, as if the AUTO\_STAT\_MODE setting were OFF for the current UPDATE STATISTICS **FORCE** operation.

The two examples that follow apply the **FORCE** keyword, respectively, to the default table scope of UPDATE STATISTICS, and to a nonfragmented individual table called **tableN**.

```
UPDATE STATISTICS FORCE;
UPDATE STATISTICS MEDIUM FOR TABLE tableN FORCE;
```

The first statement instructs the database server to take the following actions:

- Recalculate the distribution statistics in **LOW** mode for every permanent table and table fragment in the database, ignoring whether statistics for each table are stale according to their STATCHANGE thresholds.
- Store the new distributions in the system catalog tables.

The second statement instructs the database server to take the following actions:

- Recalculate the column distribution statistics in MEDIUM mode for table **tableN**.
- Update all the system catalog tables that store distribution statistics for that table.

Including the **FORCE** keyword emulates the previous UPDATE STATISTICS behavior of Informix® database servers before version 11.70.

## The AUTO keyword

The AUTO keyword causes the database server to run the UPDATE STATISTICS statement in automatic mode, but only for tables and fragments whose statistics are missing or stale. The distribution statistics are not refreshed for any tables or fragments whose STATCHANGE value is below the specified threshold.

The following statements specify the **AUTO** keyword.

```
UPDATE STATISTICS AUTO;
UPDATE STATISTICS MEDIUM FOR TABLE tableN AUTO;
```

The first statement instructs the database server to take the following actions:

- Examine every permanent table in the database, and recalculate only the missing or stale data distribution statistics for tables and fragments in which the percentage of new, deleted, or changed rows since the table distributions were last calculated exceeds the STATCHANGE threshold for that table. This might be an empty set, if no tables or table fragments exceed their STATCHANGE thresholds.
- If any tables or fragments qualified to be recalculated, store their new statistics in the appropriate system catalog tables.

The second statement instructs the database server to take the following actions: .

- If the current distribution statistics for **tableN** do not exceed the STATCHANGE threshold for that table, take no action.
- If the percentage of new, deleted, or changed rows indicate that the current distributions are stale, recalculate the column distribution statistics for table **tableN** in MEDIUM mode, and update all the system catalog tables that store distribution statistics for that table.

When sufficiently accurate statistics are already available to the query optimizer for some tables or table fragments, the AUTO option avoids unnecessary recalculations. In that case, an UPDATE STATISTICS AUTO operation requires less time, without detriment to query performance, than a corresponding UPDATE STATISTICS FORCE operation.

## Using the LOW mode option

Use the LOW option of the UPDATE STATISTICS statement to generate and update some of the relevant statistical data regarding table, row, and page-count statistics in the **sysables** system catalog table. If you do not specify any mode, the LOW mode is the default.

In Informix®, the LOW mode also generates and updates some index and column statistics for specified columns in the **syscolumns** and the **sysindexes** system catalog tables.

The LOW mode generates the least amount of information about the column. If you want the UPDATE STATISTICS statement to do minimal work, specify a column that is not part of an index. The **colmax** and **colmin** values in **syscolumns** are not updated unless there is an index on the column.

The following example updates statistics on the **customer\_num** column of the **customer** table:

```
UPDATE STATISTICS LOW FOR TABLE customer (customer_num);
```

Because the LOW mode option does not update data in the **sysdistrib** system catalog table, all distributions associated with the **customer** table remain intact, even those that already exist on the **customer\_num** column.

You can set the **USTLOW\_SAMPLE** configuration parameter or the USTLOW\_SAMPLE option of the SET ENVIRONMENT statement to enable sampling during the gathering of index statistics for UPDATE STATISTICS operations in LOW mode, as in the following example:

```
SET ENVIRONMENT USTLOW_SAMPLE ON;  
UPDATE STATISTICS LOW FOR TABLE items (quantity,total_price);
```

If the **USTLOW\_SAMPLE** configuration parameter value is zero, the default behavior for all sessions of the server instance is for LOW mode sampling to be disabled. In this example, however, the UPDATE STATISTICS LOW statement uses sampling, because the **ON** setting in the preceding SET ENVIRONMENT USTLOW\_SAMPLE statement overrides the **USTLOW\_SAMPLE** setting for subsequent LOW mode statistical operations in the same session. For more information, see [USTLOW\\_SAMPLE environment option on page 962](#).

---

## Using the DROP DISTRIBUTIONS Option

Use the DROP DISTRIBUTIONS option to force the removal of distribution information from the **sysdistrib** system catalog table.

When you specify the DROP DISTRIBUTIONS option, the database server removes the existing distribution data for the column or columns that you specify. If you do not specify any columns, the database server removes all the distribution data for that table.

You must have the DBA privilege or be owner of the table to use this option.

The following example shows how to remove distributions for the **customer\_num** column in the **customer** table:

```
UPDATE STATISTICS LOW  
FOR TABLE customer (customer_num) DROP DISTRIBUTIONS;
```

As the example shows, you drop the distribution data at the same time you update the statistical data that the LOW mode option generates.

## Using the DROP DISTRIBUTIONS ONLY Option

Use the DROP DISTRIBUTIONS ONLY option to remove distribution information from the **sysdistrib** table and update the **systables.version** column in the system catalog for those tables whose distributions were dropped, without gathering any LOW mode table and index statistics.

If you specify both the DROP DISTRIBUTIONS ONLY option and the FOR TABLE clause, Informix® removes the existing distribution data for the set of columns of the *table* that the FOR TABLE clause specifies (or for all columns, if you provide no *column* specification), but does not gather any LOW mode table and index statistics.

You must have the DBA privilege or be owner of the table to use this option.

The following example removes distributions for the **customer\_num** column in the **customer** table:

```
UPDATE STATISTICS LOW
FOR TABLE customer (customer_num) DROP DISTRIBUTIONS ONLY;
```

This drops the **customer.customer\_num** distribution data without updating the statistical information that the LOW mode option generates when the ONLY keyword does not follow the DROP DISTRIBUTIONS keywords. This example deletes from the system catalog any row describing **customer.customer\_num** from the **sysdistrib** table, and updates the **version** number for **customer** in the **systables** table. None of the other LOW mode updates are performed on **systables**, so the **nrow** and **npused** column values are unchanged by this example, and the **syscolumns**, **sysfragments** and **sysindexes** tables of the system catalog are not updated. The LOW keyword has no effect in this example, but the DROP DISTRIBUTIONS ONLY option is not available in MEDIUM or HIGH mode.

Because it specifies no FOR TABLE clause, the next example drops all rows from the **sysdistrib** table and updates the **systables.version** column in the system catalog for all tables in the database.

```
UPDATE STATISTICS DROP DISTRIBUTIONS ONLY;
```

## Using the MEDIUM mode option

Use the MEDIUM mode option to update the same statistics that you can perform with the LOW mode option, and also generate statistics about the distribution of data values for each specified column.

After UPDATE STATISTICS MEDIUM has been run on a table, the query optimizer typically chooses a more efficient execution plan, compared to the same SELECT statement when only LOW mode column distribution statistics are available for the table. column

The database server places distribution information in the **sysdistrib** system catalog table, and in other system catalog tables for fragmented tables that use distributed storage.

If you use the MEDIUM mode option, the database server scans tables at least once and takes longer to execute on a given table than the LOW mode option.

When you use the MEDIUM mode option, the data distributions are obtained by sampling a percentage of data rows, using a statistical confidence level that you specify, or else a default confidence level of 95 percent. You can also specify an explicit minimum sampling size in the Resolution clause. Because the MEDIUM sample size is usually much smaller than the actual number of rows, this mode executes more quickly than the HIGH mode.

In distributions obtained by sampling, the results can vary, because different samples of rows can have different sampling errors. If the results vary significantly, you can use the Resolution clause to increase the sampling size, or to lower the *percent*, or to increase the *confidence* level to obtain more consistent results.

If the Resolution clause specifies no *percent* of sampled rows per bin, the default average percentage of the sample in each bin is 2.5, which divides the range into approximately 40 intervals. If you do not specify a value for *confidence* level, the default level is 0.95. This value can be roughly interpreted to mean that 95 times out of 100, the difference between the MEDIUM estimate and the exact value from HIGH distributions is not statistically significant.

Distributions are not calculated, however, for LVARCHAR, BYTE, or TEXT columns.

You must have the DBA privilege or be the owner of the table to create MEDIUM mode distributions. For more information on the MEDIUM and HIGH mode options, see the [Resolution Clause on page 1065](#).

---

#### Related information

[Performance considerations of UPDATE STATISTICS statements on page 1072](#)

## Using the HIGH mode option

Use the HIGH mode option to update the same statistics that you can calculate with the MEDIUM mode option. The difference between UPDATE STATISTICS HIGH and UPDATE STATISTICS MEDIUM is the number of rows sampled.

UPDATE STATISTICS HIGH scans the entire table, while UPDATE STATISTICS MEDIUM samples only a subset of rows, based on the confidence and resolution used by the UPDATE STATISTICS statement.

For indexed tables that already have MEDIUM mode distribution statistics available for every column, the query optimizer typically chooses more efficient execution plans after you run UPDATE STATISTICS HIGH on every column that is part of an index key.

The database server places distribution information in the **sysdistrib** system catalog table, and in other system catalog tables for fragmented tables that use distributed storage.

If you do not specify a Resolution clause, the default percentage of data distributed to every bin is 0.5, a value that partitions the range of values for each column into approximately 200 intervals.

The constructed distribution is exact. Because more information is gathered, this mode executes more slowly than LOW or MEDIUM modes. If you use the HIGH mode option of UPDATE STATISTICS, the database server can take considerable time to gather the information across the database, particularly a database with large tables. The HIGH mode might scan each table several times for each column. To minimize processing time, specify a table name and column names within that table, rather than accept the default scope of all tables.

Distributions are not calculated, however, for LVARCHAR, BYTE, or TEXT columns.

You must have the DBA privilege or be the owner of the table to create HIGH mode distributions. For more information on the MEDIUM and HIGH mode options, see the topic [Resolution Clause on page 1065](#).

---

#### Related information

[Performance considerations of UPDATE STATISTICS statements on page 1072](#)

## Resolution Clause

Use the Resolution clause in MEDIUM or HIGH mode to adjust the size of the distribution bins, and to avoid calculating data on indexes.

In MEDIUM mode only, you can also use the Resolution clause to specify a lower limit to the sampling size and to adjust the confidence level.

Resolution Clause

Resolution Clause for MEDIUM Mode Resolution Clause for HIGH Mode

Resolution Clause for MEDIUM Mode

**SAMPLING SIZE** *min*

**RESOLUTION***percent*

*confidence*

**DISTRIBUTIONS ONLY**

Resolution Clause for HIGH Mode

**RESOLUTION***percent*

**DISTRIBUTIONS ONLY**

| Element           | Description  | Restrictions  | Syntax   |
|-------------------|--|---|--|
| <i>confidence</i> | Estimated likelihood that sampling in MEDIUM mode produces results equivalent to the exact HIGH mode. Default level is 0.95. | Must be within the range from 0.80 (minimum) to 0.99 (maximum)                | <a href="#">Literal</a><br><a href="#">Number on page 1419</a> |
| <i>percent</i>    | Average percentage of the sample in each distribution bin. Default is 2.5 for MEDIUM and 0.5 for HIGH.                       | Minimum value is $1/nrows$ , for <i>nrows</i> the number of rows in the table | <a href="#">Literal</a><br><a href="#">Number on page 1419</a> |
| <i>min</i>        | The minimum integer number of randomly selected rows on which to generate the data distributions                             | Must be greater than zero but cannot exceed <i>nrows</i>                      | <a href="#">Literal</a><br><a href="#">Number on page 1419</a> |

A *distribution* is a mapping of the data in a column into a set of column values, ordered by magnitude or by collation. The range of these sample values is partitioned into disjunct intervals, called *bins*, each containing an approximately equal portion of the sample of column values. For example, if one bin holds 2 percent of the data, approximately 50 such intervals hold the entire sample.

Some statistical texts call these bins *equivalence categories*. Each contains a disjunct subset of the range of the data values that are sampled from the column.

If you include the RESOLUTION keyword, it must be followed by a literal number, specifying the *percent* of values in each bin. In MEDIUM mode, it can be followed by either one or two literal numbers, with the optional second number specifying the *confidence* level, as in this example:

```
UPDATE STATISTICS MEDIUM FOR TABLE orders  
RESOLUTION 4 0.90 DISTRIBUTIONS ONLY;
```

This specifies 4% of the data per bin, implying approximately 25 bins, and a confidence level of 90%, and no examination of index data. If the 0.90 value were omitted, then the default level of confidence would have been in effect. If the RESOLUTION keyword and both numeric values were omitted, then default values for *percent* (2.5%) and for *confidence* (0.95) would be used.

The query optimizer estimates the selectivity of a WHERE clause by examining, for each column included in the WHERE clause, the proportional occurrence of the data values contained in the column.

You cannot create distributions for BYTE or TEXT columns. If you include a BYTE or TEXT column in an UPDATE STATISTICS statement that specifies MEDIUM or HIGH distributions, no distributions are created for those columns. Distributions are constructed for other columns in the list, however, and the statement does not return an error.

Columns of the VARCHAR data type do not use overflow bins, even when multiple bins are being used for duplicate values.

You can use the first two parameters of the **DBUPSPACE** environment variable to constrain the disk space and memory resources that the UPDATE STATISTICS statement can use to sort data when it constructs column distributions. These settings affect performance, because they determine how many times the database server scans the specified table to construct each distribution. (A third **DBUPSPACE** parameter can control whether UPDATE STATISTICS sorts with indexes when calculating column distributions, and whether the **explain** output file stores the plan by which the column distributions are calculated.)

---

[Default name and location of the explain output file on UNIX on page 965](#)

[Default name and location of the output file on Windows on page 966](#)

## Specifying the SAMPLING SIZE

In MEDIUM mode, you can optionally use the SAMPLING SIZE keywords to specify the minimum number of rows to sample for calculating column distribution statistics. If the Resolution clause omits the RESOLUTION keyword and specifies no *confidence* level and no *percent* value, then the number of rows that Informix® samples will be the larger of the following two values:

- The *min* value that you specify immediately after the SAMPLING SIZE keywords
- The sampling size that is required for the default *percent* of rows in each bin (2.5%) and for the minimum *confidence* level (0.80).

If a sampling size is specified in a Resolution clause that includes explicit values for both the average *percent* of sampled rows per bin and for the *confidence* level, then the number of sampled rows will be the larger of these two values:

- The *min* value that you specify immediately after the SAMPLING SIZE keywords
- The sampling size that is required for the specified *percent* of rows and for the specified *confidence* level.

If a sampling size is specified in a Resolution clause that includes an average *percentage* value but sets no *confidence* level, then the minimum *confidence* value of 0.80 is used to calculate the actual sampling size for Informix® to use if the specified *size* is smaller.

For example, the following statement calculates statistics for two columns of the **customer** table, without updating index information. At least 200 rows will be sampled, but the actual size of the sample might be larger than 200 if more rows are required to provide the default 0.80 confidence level for a sample distribution that uses approximately 50 equivalence categories, with an average percentage of 2% of the sampled values in each bin.

```
UPDATE STATISTICS MEDIUM FOR TABLE customer (city, state)
  SAMPLING SIZE 200 RESOLUTION 2 DISTRIBUTIONS ONLY;
```

Whether or not you include an explicit SAMPLING SIZE specification in the Resolution clause, Informix® records in the system catalog the actual sampling size (as a percentage of the total number of rows in the table) at the time of MEDIUM mode UPDATE STATISTICS creation.

## Using the DISTRIBUTIONS ONLY Option to Suppress Index Information

In Informix®, when you specify the DISTRIBUTIONS ONLY option, you do not update index information. This option does not affect existing index information.

Use this option to avoid the examination of index information that can consume considerable processing time.

This option does not affect the recalculation of information on tables, such as the number of pages used, the number of rows, and fragment information. UPDATE STATISTICS needs this information to construct accurate column distributions and requires little time and system resources to collect it.

Do not confuse this DISTRIBUTIONS ONLY option with the DROP DISTRIBUTIONS ONLY option of LOW mode, whose syntax and semantics are not supported in MEDIUM or HIGH mode. For information on how to suppress the collection of column distributions, see [Using the DROP DISTRIBUTIONS ONLY Option on page 1062](#).

## Using DBUPSPACE Settings to Suppress Index Information

You can also prevent indexes from being used by UPDATE STATISTICS operations in sorting rows by setting the third parameter of the **DBUPSPACE** environment variable to a value of 1. Refer to Chapter 3 of the *Informix® Guide to SQL: Reference* for information about the **DBSPACETEMP** and **DBUPSPACE** environment variables, which can restrict the system resources that are available for UPDATE STATISTICS operations. (The database server uses the storage locations that **DBSPACETEMP** specifies only when you use the HIGH option of UPDATE STATISTICS.)

## Output for UPDATE STATISTICS from the SET EXPLAIN Statement

The SET EXPLAIN statement can display the plan that UPDATE STATISTICS uses to generate column distributions. The following output is based on the default **DBUPSPACE** value of 15 megabytes of sort memory, which in this example requires two passes to sort the 21.9 megabytes of data:

```

UPDATE STATISTICS:
=====

Table: zelaine.t1
Mode: HIGH
Number of Bins: 267 Bin size 2505
Sort data 21.9 MB Sort memory granted 15.0 MB
Estimated number of table scans 2
PASS #1 b
PASS #2 a
Scan 9 Sort 1 Build 2 Insert 0 Close 0 Total 12
Completed pass 1 in 0 minutes 12 seconds
Scan 5 Sort 2 Build 1 Insert 0 Close 0 Total 8
Completed pass 2 in 0 minutes 8 seconds

```

## Routine Statistics

Before executing a new SPL routine for the first time, the database server optimizes the DML statements in the SPL routine. Immediately before you invoke that SPL routine, however, you can reduce the risk of error if you use the Routine Statistics syntax of UPDATE STATISTICS to update its query execution plans, some of which might reference tables whose schemas have been modified by DDL operations of concurrent sessions.

Optimization makes the code depend on the structure of tables referenced by the routine. If a DDL operation modifies the schema of a referenced table after the routine is optimized, but before it is executed, the routine can fail with an error.

This failure typically does not occur, however, if an index is added or dropped while automatic recompilation is enabled for routines referencing tables that ALTER TABLE, CREATE INDEX, or DROP INDEX operations have modified. This is the default behavior of Informix®. For more information about enabling or disabling automatic reoptimization after changes to the schema of a table, see the description of the IFX\_AUTO\_REPREPARE option to the SET ENVIRONMENT statement.

When the AUTO\_REPREPARE configuration parameter and the IFX\_AUTO\_REPREPARE session environment variable are set to disable recompilation of SPL routines that reference tables whose schema has been modified, however, adding or dropping an index to a table that an SPL routine references indirectly can cause the routine to return error -710. To avoid this error after DDL operations, or to reoptimize SPL routines after table distributions might have been modified by DML operations, use the Routine Statistics segment of UPDATE STATISTICS to update the execution plans of any SPL routines that reference the table.

Routine Statistics

**FOR**

**PROCEDURE**

**FUNCTION ROUTINE**

*routine*

(

Routine Parameter List <sup>473</sup>

)

**SPECIFIC**

**PROCEDURE FUNCTION ROUTINE**

Specific Name <sup>474</sup>

| Element        | Description   | Restrictions  | Syntax                                  |
|----------------|---|---|---|
| <i>owner</i>   | Owner of the UDR  | No more than 32 bytes. Must be the authorization identifier of the owner of <i>routine</i> .  | <a href="#">Owner name on page 1488</a> |
| <i>routine</i> | Name that a CREATE FUNCTION or CREATE PROCEDURE statement declared for an SPL routine | Must exist in the database. In ANSI-compliant databases, qualify <i>routine</i> with <i>owner</i> if you are not the <i>owner</i> . | <a href="#">Identifier on page 1456</a> |

## Usage

If you change the structure of a table that an SPL routine references, you can run UPDATE STATISTICS FOR ROUTINE, FOR FUNCTION, or FOR PROCEDURE statements to reoptimize the routines that reference the table, rather than waiting until the next time an SPL routine that uses the table executes. (If a table that an SPL routine references is dropped, however, running UPDATE STATISTICS cannot prevent the SPL routine from failing with an error.)

The keywords of the Routine Statistics segment identify one or more SPL routine whose execution plan will be reoptimized.

### Keyword

#### Which Execution Plans are Reoptimized

#### FUNCTION

The plan for any SPL function with the specified name (and with parameter types that match *routine parameter list*, if parameters are supplied). If you specify the FUNCTION keyword, the UPDATE STATISTICS statement fails with an error unless the specified routine returns a value or values, with or without the WITH RESUME option.

#### PROCEDURE

The plan for any SPL procedure with the specified name (and parameter types that match *routine parameter list*, if supplied)

473. See [Routine Parameter List on page 1514](#)

474. See [Specific Name on page 1521](#)

**ROUTINE**

The plan for SPL functions and procedures with the specified name (and parameter types that match *routine parameter list*, if supplied)

**SPECIFIC**

The plan for the SPL routine called *specific name*. If you include the SPECIFIC keyword, the immediately following keyword must be either FUNCTION, PROCEDURE, or ROUTINE.

The parentheses symbols are optional if you omit the SPECIFIC keyword and include no argument list.

If you specify no routine name immediately after the FOR FUNCTION, FOR PROCEDURE, or FOR ROUTINE keywords, the execution plans are reoptimized for all SPL routines in the current database.

The database server keeps a list of tables that the SPL routine references explicitly. Whenever an explicitly referenced table is modified, the database server reoptimizes the procedure the next time the procedure is executed.

The **sysprocplan** system catalog table stores execution plans for SPL routines. Two actions can update the **sysprocplan** system catalog table:

- Execution of an SPL routine that uses a modified table
- The UPDATE STATISTICS FOR ROUTINE, FUNCTION, or PROCEDURE statement.

If you change a table that an SPL routine references, you can run UPDATE STATISTICS to reoptimize the procedures that reference the table, rather than waiting until the next time an SPL routine that uses the table executes. If a table that an SPL routine references is dropped, however, running UPDATE STATISTICS cannot prevent the SPL routine from failing with an error.

**Examples of updating statistics for a specific routine**

The following UPDATE STATISTICS FOR SPECIFIC statement instructs the database server to update statistics for an existing function named Perform\_work that returns one or more values:

```
UPDATE STATISTICS FOR SPECIFIC FUNCTION Perform_work;
```

For the same Perform\_work function, the effect of the following example is identical to that of the previous example:

```
UPDATE STATISTICS FOR SPECIFIC ROUTINE Perform_work;
```

Similarly, use the keywords SPECIFIC PROCEDURE or SPECIFIC ROUTINE to update statistics for SPECIFIC procedures that return no value.

Do not include parentheses or a parameter list after the name of the SPECIFIC routine. Because of the parentheses that follow the name of the Perform\_work function, the following statement fails with an error:

```
UPDATE STATISTICS FOR SPECIFIC ROUTINE Perform_work();
```

The database server also issues an error if parentheses enclose arguments to the SPECIFIC routine, function, or procedure.

## Altered tables that are referenced indirectly in SPL routines

After DDL operations that change the schema of a table that an SPL routine references indirectly, but not as the target of a DML operation, you might need to perform UPDATE STATISTICS operations on the modified table and on the SPL routine to avoid exceptions when the SPL routine is invoked.

If the SPL routine depends on a table that is referenced only indirectly, the database server cannot detect the need to reoptimize the procedure after that table is modified. For example, a table can be referenced indirectly if the SPL routine activates a trigger. After schema modifications of a table that is referenced by the trigger but not referenced directly by the SPL routine, the database server does not know that it should reoptimize execution plan of the SPL routine before running it. When the procedure is run after the table has been changed, error -710 can occur.

Each SPL routine is optimized the first time that it is run, not when it is created. This behavior means that an SPL routine might succeed the first time it is run, but might fail later under virtually identical circumstances, if the schema of an indirectly referenced table has been changed. The failure of an SPL routine can also be intermittent, because failure during one execution forces an internal warning to reoptimize the procedure before the next execution.

You can use either of two methods to recover from this error:

- Issue UPDATE STATISTICS FOR PROCEDURE to force reoptimization of the routine.
- Rerun the routine.

To prevent this error, you can force reoptimization of the SPL routine. To force reoptimization, execute the following statement:

```
UPDATE STATISTICS FOR PROCEDURE routine;
```

You can add this statement to your program in either of the following ways:

- Issue UPDATE STATISTICS after each statement that changes the mode of an object.
- Issue UPDATE STATISTICS FOR PROCEDURE before each invocation of the SPL routine.

For efficiency, you can put the UPDATE STATISTICS statement with the action that occurs less frequently in the program (change of object mode or execution of the procedure). In most cases, the action that occurs less frequently in the program is the change of object mode.

When you follow this method of recovering from this error, you must execute UPDATE STATISTICS FOR PROCEDURE for each SPL procedure that indirectly references the altered tables, unless the procedure also references the tables explicitly.

You can also recover from error -710 after an indirectly referenced table is altered simply by re-executing the SPL routine. The first time that the stored procedure fails, the database server marks the procedure as in need of reoptimization. The next time that you run the procedure, the database server reoptimizes the procedure before running it. Running the SPL routine twice, however, might be neither practical nor safe. A safer choice is to use the UPDATE STATISTICS FOR PROCEDURE statement to force reoptimization of the procedure.

When

## Updating statistics when you upgrade the database server

When you upgrade a database to use with a newer database server, you can use the UPDATE STATISTICS statement to convert the indexes to the form that the newer database server uses.

You can choose to convert the indexes one table at a time or for the entire database at one time. Follow the conversion guidelines that are outlined in the *Informix® Migration Guide*.

Migration to a newer database server is the only context in which the UPDATE STATISTICS statement causes table indexes to be implicitly dropped and re-created.

## Performance considerations of UPDATE STATISTICS statements

The more specific you make the list of objects that the UPDATE STATISTICS statement examines, the faster it completes execution. Limiting the number of column distributions speeds the update. Similarly, precision affects the speed of the update. If all other keywords are the same, LOW works fastest, but HIGH examines the most data.

For version 11.70 and later of the Informix® database server, the AUTO\_STAT\_MODE setting can improve the efficiency of UPDATE STATISTICS operations that refresh data distribution statistics. This enables the database server to selectively recalculate only the table or fragment distributions that have become stale as a result of DML operations since the statistics were last calculated, as determined by a change threshold that an explicit or default STATCHANGE table attribute defines. For information about how to set STATCHANGE and how to enable the automatic mode of UPDATE STATISTICS for refreshing only stale distribution statistics, see these topics:

- [Using the FORCE and AUTO keywords on page 1060](#)
- [AUTO\\_STAT\\_MODE session environment option on page 912](#)
- [STATCHANGE session environment option on page 952](#)
- [Statistics options of the CREATE TABLE statement on page 395](#)
- [Statistics options of the ALTER TABLE statement on page 163](#)

The [USTLOW\\_SAMPLE environment option on page 962](#) enables sampling during the gathering of index statistics for UPDATE STATISTICS operations in LOW mode. For an index with more than 100 K leaf pages, the gathering of statistics using sampling can increase the speed of the UPDATE STATISTICS operation.

## Examples of UPDATE STATISTICS statements

```
UPDATE STATISTICS MEDIUM;
UPDATE STATISTICS MEDIUM RESOLUTION 10;
UPDATE STATISTICS MEDIUM RESOLUTION 10 .95;
{ RESOLUTION 10, CONFIDENCE .95}
UPDATE STATISTICS MEDIUM RESOLUTION 10 DISTRIBUTIONS ONLY;
UPDATE STATISTICS MEDIUM RESOLUTION 10 .95 DISTRIBUTIONS ONLY;

UPDATE STATISTICS HIGH;
UPDATE STATISTICS HIGH RESOLUTION 10;
UPDATE STATISTICS HIGH RESOLUTION 10 DISTRIBUTIONS ONLY;
```

Resolution must be greater than 0.005 and less than or equal to 10.0. Confidence must be in the range [0.80, 0.99] (inclusive).

Examples that follow are based on the **company\_proc** procedure and **square\_w\_default** function, as defined below:

```

CREATE PROCEDURE company_proc ( no_of_items INT,
                               itm_quantity SMALLINT, sale_amount MONEY,
                               customer VARCHAR(50), sales_person VARCHAR(30) )
SPECIFIC spec_cmpy

DEFINE salesperson_proc VARCHAR(60);

-- Update the company table
INSERT INTO company_tbl VALUES (no_of_items, itm_quantity,
                                sale_amount, customer, sales_person);

-- Generate the procedure name for the variable salesperson_proc
LET salesperson_proc = sales_person || "." || "tbl" ||
    month(current) || "-" || year(current) || "_proc" ;

-- Execute the SPL procedure that the salesperson_proc
-- variable specifies
EXECUTE PROCEDURE salesperson_proc (no_of_items,
                                    itm_quantity, sale_amount, customer);
END PROCEDURE;

CREATE FUNCTION square_w_default
    (i INT DEFAULT 0) {Specifies default value of i}
RETURNING INT {Specifies return of INT value}
SPECIFIC spec_square
    DEFINE j INT; {Defines routine variable j}
    LET j = i * i; {Finds square of i and assigns it to j}
    RETURN j; {Returns value of j to calling module}
END FUNCTION;

```

The UPDATE STATISTICS examples that follow reference the **company\_proc** procedure and **square\_w\_default** function:

```

UPDATE STATISTICS FOR PROCEDURE;
UPDATE STATISTICS FOR PROCEDURE company_proc1;
UPDATE STATISTICS FOR PROCEDURE
    company_proc1(INT,SMALLINT,MONEY,VARCHAR(50), VARCHAR(30));
UPDATE STATISTICS FOR SPECIFIC PROCEDURE spec_cmpy;

UPDATE STATISTICS FOR FUNCTION;
UPDATE STATISTICS FOR FUNCTION square_w_default;
UPDATE STATISTICS FOR FUNCTION square_w_default(INT);
UPDATE STATISTICS FOR SPECIFIC FUNCTION spec_square;

```

For a discussion of the performance implications of UPDATE STATISTICS, see your *Informix® Performance Guide*.

For a discussion of how to use the **dbschema** utility to view distributions created with UPDATE STATISTICS, see the *Informix® Migration Guide*.

## WHENEVER statement

Use the WHENEVER statement to trap exceptions that occur during the execution of SQL statements. The WHENEVER statement is equivalent to placing an exception-checking routine after every SQL statement.

**Syntax****WHENEVER****SQLERROR NOT FOUND**<sup>475</sup>**SQLWARNING**<sup>475</sup>**ERROR****CONTINUE****GOTO GO TO***:label*<sup>475</sup>*label***CALL***routine***STOP**

| Element        | Description   | Restrictions                                  | Syntax                                  |
|----------------|---|---|---|
| <i>label</i>   | Statement label to which program control transfers when an exception occurs | Must exist in the same source-code module.    | Language-specific                       |
| <i>routine</i> | Name of a user-defined routine (UDR) to be invoked when an exception occurs | No arguments; UDR must exist at compile time. | <a href="#">Identifier on page 1456</a> |

**Usage****Important:** Use this statement only with Informix® ESQL/C.

The following table summarizes the types of exceptions that you can check with the WHENEVER statement.

| Type of exception | WHENEVER Keyword  | For More Information                          |
|-------------------|-------------------|---|
| Errors            | SQLERROR or ERROR | <a href="#">SQLERROR Keyword on page 1076</a> |

475. Informix® extension

| Type of exception        | WHENEVER Keyword                                | For More Information |
|--------------------------|---|----------------------|
| Warnings                 | <a href="#">SQLWARNING Keyword on page 1076</a> |                      |
| Not Found or End of Data | <a href="#">NOT FOUND Keywords on page 1077</a> |                      |

Programs that do not use the `WHENEVER` statement do not automatically abort when an exception occurs. Such programs must explicitly check for exceptions and take whatever corrective action their logic specifies. If you do not check for exceptions, the program simply continues running. If errors occur, however, the program might not perform its intended purpose.

The first keyword that follows `WHENEVER` specifies some type of exceptional condition; the last part of the statement specifies some action to take when the exception is encountered (or no action, if `CONTINUE` is specified). The following table summarizes possible actions that `WHENEVER` can specify.

| Type of action                        | WHENEVER keyword                              | For more information                      |
|---------------------------------------|---|---|
| Continue program execution            | <a href="#">CONTINUE Keyword on page 1077</a> |   |
| Stop program execution                | <a href="#">STOP Keyword on page 1077</a>     |   |
| Transfer control to a specified label | <code>GOTO GO TO</code>                       | <a href="#">GOTO Keyword on page 1077</a> |
| Transfer control to a UDR             | <a href="#">CALL Clause on page 1078</a>      |   |

[BEGIN WORK statement on page 176](#)

## The Scope of `WHENEVER`

`WHENEVER` is a preprocessor directive, rather than an executable statement. The Informix® ESQL/C preprocessor, not the database server, handles the interpretation of the `WHENEVER` statement. When the preprocessor encounters a `WHENEVER` statement in the Informix® ESQL/C source file, it inserts appropriate code into the preprocessed code after each SQL statement, based on the exception and the action that `WHENEVER` specifies. The scope of the `WHENEVER` statement begins where the statement appears in the source module and remains in effect until the preprocessor encounters one or the other of the following things while sequentially processing the source module:

- The next `WHENEVER` statement with the same condition (`SQLERROR`, `SQLWARNING`, or `NOT FOUND`) in the same source module
- The end of the source module

The following Informix® ESQL/C example program has three `WHENEVER` statements, two of which are `WHENEVER SQLERROR` statements. Line 4 uses `STOP` with `SQLERROR` to override the default `CONTINUE` action for errors.

Line 8 specifies the CONTINUE keyword to return the handling of errors to the default behavior. For all SQL statements between lines 4 and 8, the preprocessor inserts code that checks for errors and halts program execution if an error occurs. Therefore, any errors that the INSERT statement on line 6 generates cause the program to stop.

After line 8, the preprocessor does not insert code to check for errors after SQL statements. Therefore, any errors that the INSERT statement (line 10), the SELECT statement (line 11), and DISCONNECT statement (line 12) generate are ignored. The SELECT statement, however, does not stop program execution if it does not locate any rows; the WHENEVER statement on line 7 tells the program to continue if such an exception occurs:

```

1  main()
2  {
3  EXEC SQL connect to 'test';
4  EXEC SQL WHENEVER SQLERROR STOP;
5  printf("\n\nGoing to try first insert\n\n");
6  EXEC SQL insert into test_color values ('green');
7  EXEC SQL WHENEVER NOT FOUND CONTINUE;
8  EXEC SQL WHENEVER SQLERROR CONTINUE;
9  printf("\n\nGoing to try second insert\n\n");
10 EXEC SQL insert into test_color values ('blue');
11 EXEC SQL select paint_type from paint where color='red';
12 EXEC SQL disconnect all;
13 printf("\n\nProgram over\n\n");
14 }
```

## SQLERROR Keyword

If you use the SQLERROR keyword, any SQL statement that encounters an error is handled as the WHENEVER SQLERROR statement directs. If an error occurs, the **sqlcode** variable (**sqlca.sqlcode**, **SQLCODE**) is set to a value less than zero (0) and the SQLSTATE variable is set to a class code with a value greater than 02.

The next example terminates program execution if an SQL error is detected:

```
WHENEVER SQLERROR STOP
```

If you do not include any WHENEVER SQLERROR statements in a program, the default action for WHENEVER SQLERROR is CONTINUE.

## ERROR Keyword

Within the WHENEVER statement (and only in this context), the keyword ERROR is a synonym for the SQLERROR keyword.

## SQLWARNING Keyword

If you use the SQLWARNING keyword, any SQL statement that generates a warning is handled as the WHENEVER SQLWARNING statement directs. If a warning occurs, the first field (**sqlca.sqlwarn.sqlwarn0**) of the warning structure in SQLCA is set to w, and the SQLSTATE variable is set to a class code of 01.

Besides the first field of the warning structure, a warning also sets an additional field to `w`. The field that is set indicates what type of warning occurred.

The next statement causes execution to stop if a warning condition exists:

```
WHENEVER SQLWARNING STOP
```

If you do not use any `WHENEVER SQLWARNING` statements in a program, the default action for `WHENEVER SQLWARNING` is `CONTINUE`.

## NOT FOUND Keywords

If you use the `NOT FOUND` keywords, exception handling for `SELECT` and `FETCH` statements (including implicit `SELECT` and `FETCH` statements in `FOREACH` and `UNLOAD` statements) is treated differently from other SQL statements. The `NOT FOUND` keyword checks for the following cases:

- The **End of Data** condition: a `FETCH` statement that attempts to get a row beyond the first or last row in the active set
- The **Not Found** condition: a `SELECT` statement that returns no rows

In each case, the `sqlcode` variable is set to `100`, and the `SQLSTATE` variable has a class code of `02`. For the name of the `sqlcode` variable in each Informix® product, see the table in [SQLERROR Keyword on page 1076](#).

The following statement calls the `no_rows()` function each time the `NOT FOUND` condition exists:

```
WHENEVER NOT FOUND CALL no_rows
```

If you do not use any `WHENEVER NOT FOUND` statements in a program, the default action for `WHENEVER NOT FOUND` is `CONTINUE`.

## CONTINUE Keyword

Use the `CONTINUE` keyword to instruct the program to ignore the exception and to continue execution at the next statement after the SQL statement. The default action for all exceptions is `CONTINUE`. You can use this keyword to turn off a previously specified action for an exceptional condition.

## STOP Keyword

Use the `STOP` keyword to instruct the program to stop execution when the specified exception occurs. The following statement halts execution of an ESQL/C program each time that an SQL statement generates a warning:

```
EXEC SQL WHENEVER SQLWARNING STOP;
```

## GOTO Keyword

Use the GOTO clause to transfer control to the statement that the label identifies when a specified exception occurs. The GOTO and GO TO keywords are ANSI-compliant syntax for this feature of embedded SQL languages like ESQL/C. The following Informix® ESQL/C code fragment shows a WHENEVER statement that transfers control to the label **missing** each time that the NOT FOUND condition occurs:

```
query_data()
...
EXEC SQL WHENEVER NOT FOUND GO TO missing;
```

```
...
EXEC SQL fetch lname into :lname;
...
missing:
    printf("No Customers Found\n");
```

Within the scope of the WHENEVER GOTO statement, you must define the labeled statement in *each* routine that contains SQL statements. If your program contains more than one user-defined function, you might need to include the labeled statement and its code in *each* function.

If the preprocessor encounters an SQL statement within the scope of a WHENEVER ... GOTO statement, but within a routine that does not have the specified label, the preprocessor tries to insert the code associated with the labeled statement, but generates an error when it cannot find the label.

To correct this error, either put a labeled statement with the same label name in each UDR, or issue another WHENEVER statement to reset the error condition, or use the CALL clause to call a separate function.

## CALL Clause

Use the CALL clause to transfer program control to the specified UDR when the specified type of exception occurs. Do not include parentheses after the UDR name. The following WHENEVER statement causes the program to call the **error\_recovery()** function if the program detects an error:

```
EXEC SQL WHENEVER SQLERROR CALL error_recovery;
```

When the UDR returns, execution resumes at the next statement after the line that is causing the error. If you want to halt execution when an error occurs, include statements that terminate the program as part of the specified UDR.

Observe the following restrictions on the specified routine:

- The UDR cannot accept arguments nor can it return values. If it needs external information, use global variables or the WHENEVER ... GOTO option to transfer program control to a label that calls the UDR.
- You cannot specify the name of an SPL routine in the CALL clause. To call an SPL routine, use the CALL clause to invoke a UDR that contains the EXECUTE FUNCTION (or EXECUTE PROCEDURE) statement.
- Make sure that all functions within the scope of WHENEVER ... CALL statements can find a declaration of the specified function.

## Related Statements

For discussions on exception handling and error checking, see the *Informix® ESQL/C Programmer's Manual*.

## WITH statement (Common Table Expressions)

A common table expression (CTE) is a named temporary result set that exists within the scope of a single statement and that can be referred to later within that statement, possibly multiple times. The following discussion describes how to write statements that use CTEs.

### Syntax

```
|--WITH -----> (1)
      .-,-----+
      V                                     |
(1)---- cte_name ---+-----AS (Subset of SELECT statement)---+> (2)
          |      .-,----- .      |
          |      V               |   |
          |      '-(----column----)-' |
(2)----- SELECT/UPDATE/INSERT/DELETE statement
```

| Element         | Description   | Restrictions   | Syntax     |
|-----------------|---|--|------------|
| <i>column</i>   | Name that you declare here for a column in CTE.<br>Default is a column name from Projection list of SELECT  |  | Identifier |
| <i>cte_name</i> | Name that you declare here for the table expression, and it can be used as a virtual table in the following SELECT/UPDATE/INSERT/DELETE statement | Must be unique among view, table, sequence, and synonym names in the database. | Identifier |

### Usage

WITH statement can be run directly like SELECT/UPDATE/INSERT/DELETE statements, and it can be used with

- CREATE VIEW
- CREATE TRIGGER
- CREATE PROCEDURE/FUNCTION

### Recursive CTE

A recursive CTE starts with either one non-recursive sub-query or several non-recursive sub-queries joined by UNION or UNION ALL and ends with exactly one recursive sub-query joined by UNION ALL. A recursive sub-query references the CTE being defined.

```

WITH recursive_cte AS (
    <initial subquery>
    UNION ALL
    <recursive subquery>
) SELECT ...

```

**Example****Example 1: Recursive query computing the factorial of numbers from 0 to 9**

```

WITH temp (n, fact) AS (
    SELECT 0, 1 -- Initial Subquery
    UNION ALL
    SELECT n+1, (n+1)*fact FROM temp -- Recursive Subquery
    WHERE n < 9)
SELECT * FROM temp;

```

Other example of computing Fibonacci Numbers

```

WITH fib(p, n) as (
    select 0, 1 -- initial subquery
    UNION ALL -- 'UNION ALL'
    select n, (p+n) from fib -- recursive subquery
    where n < 100 -- terminate condition
)
select p as fn from fib;

```

| fn  |
|-----|
| 0   |
| 1   |
| 1   |
| 2   |
| ... |
| 34  |
| 55  |
| 89  |

**Example****Example 2: Recursive CTE optional Cycle clause**

```

CYCLE <column list> SET <cycle pseudo column>
    TO <value1> DEFAULT <value2>

create table cycle (id int, pid int);
insert into cycle values (1,2);
insert into cycle values (2,1);

WITH cte AS (
    select id, pid from cycle where id = 1 UNION ALL
    select t.id, t.pid
    from cycle t, cte where t.pid = cte.id)
cycle id set iscycle to "yes" default "no"
SELECT id, pid, iscycle from cte ;

```

| id | pid | iscycle |
|----|-----|---------|
| 1  | 2   | no      |
| 2  | 1   | yes     |

**Example**

### Example 3: Recursive CTE Loops

```
with cte(n) as
(
  select 1
  UNION ALL
  select n+1 from cte
)
select first 2 n from cte;          -- 2 rows return

without the 'FIRST 2' the query will loop till integer limit error.
```

## SPL statements

These topics describe Stored Procedure Language (SPL) statements, which you use to write SPL routines. You can store these routines in the database as user-defined routines (UDRs).

SPL routines (formerly referred to as *stored procedures*) are effective tools for controlling SQL activity. This chapter contains descriptions of the SPL statements. The description of each statement includes the following information:

- A brief introduction that explains the effect of the statement
- A syntax diagram that shows how to enter the statement correctly
- A syntax table that explains each input parameter in the syntax diagram
- Rules of usage, including examples that illustrate these rules

If a statement is composed of multiple clauses, the statement description provides information about each clause.

For an overview of the SPL language and task-oriented information about creating and using SPL routines, see the *Informix® Guide to SQL: Tutorial*.

For an overview with detailed examples of how to create and use prepared objects and Dynamic SQL in SPL routines, see this article: [Dynamic SQL support in Informix® Dynamic Server Stored Procedure Language](#).

Informix® can create an SPL function with the CREATE PROCEDURE or CREATE PROCEDURE FROM statement, but requires the CREATE FUNCTION or CREATE FUNCTION FROM statement for external functions. It is recommended, however, that you use the CREATE FUNCTION or CREATE FUNCTION FROM statement to create new user-defined functions.

---

#### Related information

[Overloading the Name of a Function on page 247](#)

## << *Label* >> statement

Use the <<*label*>> statement of SPL to declare a statement label or a loop label.

- A *statement label* is an SQL identifier, delimited by double angle-brackets, immediately preceding a statement within a statement block to which the GOTO statement of SPL can transfer control of program execution.
- A *loop label* is an SQL identifier, delimited by double angle-brackets, immediately preceding a loop statement of SPL. The same label, without double angle-bracket delimiters, can follow the END LOOP keywords, or END FOR keywords, or END WHILE keywords that terminate the labeled loop. The EXIT *label* statement can pass control of program execution to whatever statement immediately follows the undelimited loop label.

Note that *label* is not a keyword of the <<*label*>> statement, but is a placeholder for some specific user-defined identifier of the statement label or loop label that the <<*label*>> statement declares.

## Syntax

<<*label*>>

| Element      | Description  | Restrictions   | Syntax                                  |
|--------------|--|--|---|
| <i>label</i> | Name that you declare here for a statement label or for a loop label | Must be unique among the identifiers of statement labels and of loop labels within the SPL routine | <a href="#">Identifier on page 1456</a> |

## Usage

You can use the <<*Label*>> statement in two ways:

- To declare a *statement label* before an executable statement to which the GOTO statement of SPL can transfer control of execution. The SPL statement that immediately follows the statement label declaration is called a *labeled statement*.
- To declare a *loop label* immediately before a LOOP, FOR, or WHILE statement of SPL. The LOOP, FOR, or WHILE statement that immediately follows the loop label declaration is called a *labeled loop*.

The EXIT *label* or EXIT *label* WHEN (*condition*) statement can exit from the labeled loop, passing control of execution to the statement immediately following an END LOOP *label* statement. The *label* specified in the EXIT statement can match the label identifier of the labeled loop of the EXIT statement, or if loops are nested, this *label* can match the label of an outer labeled loop. In either case, the EXIT *label* statement passes control to a statement that follows an END LOOP *label* statement that specifies the same loop label. This EXIT *label* behavior differs from that of the GOTO *label* statement, which passes control to the statement that follows the declaration of the specified statement label.

The following restrictions apply to labels in SPL routines:

- The name of a statement label must be within the scope of reference of the GOTO statement.
- The GOTO option of the WHENEVER statement of SQL cannot reference an SPL statement label, because the WHENEVER statement is valid only in ESQL/C applications.
- The GOTO statement of SPL cannot reference a loop label.
- The GOTO statement cannot reference a statement label within an ON EXCEPTION statement block.

- A statement label cannot be declared within an ON EXCEPTION statement block.
- The label name must be unique among statement labels and loop labels within the SPL routine.

## Examples of Labels

The following example illustrates a statement label called **increment\_x** within an SPL routine:

```
DEFINE x INT;
LET x = 0;
BEGIN
  <<increment_x>>
  BEGIN
    LET x = x + 1;
  END;
  IF x < 10 THEN
    GOTO increment_x;
  END IF;
END;
END PROCEDURE;
```

The following program fragment shows an example of a labeled FOR loop:

```
<<lb_for>>
FOR i IN 1..5
  i := i + 1 ;
END FOR lb_for;
```

The following program fragment illustrates a labeled loop from which an EXIT *label* statement can exit:

```
<<outer>>
LOOP
...
LOOP
...
EXIT outer WHEN ... -- exit from both loops
END LOOP;
...
END LOOP outer;
```

## CALL

Use the CALL statement to execute a user-defined routine (UDR) from within an SPL routine.

**Syntax****CALL***procedure*

```
(
, Argument476
)
```

*function*

```
(
, Argument476
)
```

**RETURNING***, data\_var**routine\_var***RETURNING***, data\_var*

| Element                               | Description  | Restrictions   | Syntax                                  |
|---------------------------------------|--|--|---|
| <i>data_var</i>                       | Variable to receive the values <i>function</i> returns | The data type of <i>data_var</i> must be appropriate for the returned value      | <a href="#">Identifier on page 1456</a> |
| <i>function</i> ,<br><i>procedure</i> | User-defined function or procedure                     | The function or procedure must exist   | <a href="#">Identifier on page 1456</a> |
| <i>routine_var</i>                    | Variable that contains the name of a UDR               | Must be a character data type that contains the non-NULL name of an existing UDR | <a href="#">Identifier on page 1456</a> |

**Usage**

The CALL statement invokes a UDR. The CALL statement is identical in behavior to the EXECUTE PROCEDURE and EXECUTE FUNCTION statements, but you can only use CALL from within an SPL routine.

You can use CALL in Informix® ESQL/C programs or with DB-Access, but only if the statement is in an SPL routine that the program or DB-Access executes.

When you use CALL to invoke a user-defined function that you specify by its *function* identifier or as a *routine\_var* that stores the identifier of the function, the CALL statement must also include the RETURNING clause.

The CALL statement cannot invoke an iterator TABLE function from a subquery in the FROM clause of a SELECT statement. For the syntax of iterator TABLE functions, see [Iterator Functions on page 801](#).

476. See [Arguments on page 1433](#)

**Related reference**[EXECUTE FUNCTION statement on page 549](#)[EXECUTE PROCEDURE statement on page 557](#)[Arguments on page 1433](#)

## Specifying Arguments

The argument list of the CALL statement, delimited by parentheses, immediately follows the name of the UDR. If you include no arguments, empty parentheses must follow the name of the UDR. If the list includes more arguments than the UDR expects, you receive an error.

If CALL specifies fewer arguments than the UDR expects, the arguments are said to be missing. The database server initializes missing arguments to their corresponding default values. (See CREATE PROCEDURE and CREATE FUNCTION.) This initialization occurs before the first executable statement in the body of the UDR. If missing arguments do not have default values, they are initialized to the value of UNDEFINED. An attempt to use any variable of UNDEFINED value results in an error.

In each UDR call, you have the option of specifying parameter names for the arguments that you pass to the UDR. Each of the following examples are valid for a UDR that expects character arguments named `t`, `n`, and `d`, in that order:

```
CALL add_col (t='customer', n = 'newint', d ='integer');
CALL add_col('customer','newint','integer');
```

Both of the CALL statements above have the same effect.

The syntax of the argument list is described in more detail in the topic [Arguments on page 1433](#).

## Receiving input from the called UDR

The RETURNING clause specifies the variable that receives values that the function returns to its calling context.

The following example shows two UDR calls:

```
CREATE PROCEDURE not_much()
  DEFINE i, j, k INT;
  CALL no_args (10,20);
  CALL yes_args (5) RETURNING i, j, k;
END PROCEDURE;
```

The first routine call (**no\_args**) expects no returned values. The second routine call is to a function (**yes\_args**), which expects three returned values. The **not\_much()** procedure declares three integer variables (**i**, **j**, and **k**) to receive the returned values from **yes\_args**.

## CASE

Use the CASE statement when program execution needs to take exactly one among multiple branches, depending on the value of an SPL variable or of a simple expression. The CASE statement is a logical alternative to the IF statement.

**Syntax****CASE***value\_expr*

ELSE Clause

**WHEN***constant\_expr* **NULL****THEN**Statement Block<sup>477</sup>

ELSE Clause

**END CASE**

ELSE Clause

**ELSE**Statement Block<sup>477</sup>

| Element              | Description                               | Restrictions   | Syntax  |
|----------------------|---|--|---|
| <i>constant_expr</i> | Expression that specifies a literal value | Can be a literal number, quoted string, literal datetime, or literal interval. The data type must be compatible with the data type of <i>value_expr</i> .  | <a href="#">Constant Expressions on page 1235</a> |
| <i>value_expr</i>    | Expression that returns a value           | An SPL variable or any other type of expression that returns a value or NULL. The data type cannot be a large object (BLOB, BYTE, CLOB, TEXT), a collection, nor a user-defined OPAQUE or DISTINCT type. Among built-in OPAQUE types, only BOOLEAN and LVARCHAR are valid. | <a href="#">Expression on page 1193</a>           |

**Usage**

You can use the CASE statement to create a set of conditional branches within an SPL routine. The WHEN and the ELSE clauses are optional, but you must include at least one of them.

- If you include no WHEN clause and no ELSE clause, the CASE statement fails with a syntax error.
- If you include no ELSE clause, but no WHEN clause specifies a *constant\_expr* that matches the *value\_expr*, the CASE statement fails with runtime error -26062 when the routine is executed.

Do not confuse the CASE statement with CASE expressions of SQL. (CASE expressions support the same keywords as the CASE statement, but use different syntax and semantics to evaluate *conditions* that you specify. CASE expressions return a single value or NULL, as described in [CASE Expressions on page 1227](#).)

**How the database server executes a CASE statement**

The database server executes the CASE statement by taking the following sequence of actions:

- The database server evaluates the *value\_expr* expression.
- If the resulting value matches a literal value specified as the *constant\_expr* specification of a WHEN clause, the database server executes the statement block that immediately follows the THEN keyword in that WHEN clause.

477. See [Statement Block on page 1522](#)

- If the value to which the *value\_expr* parameter evaluates matches the *constant\_expr* specification in more than one WHEN clause, the database server executes the statement block that immediately follows the THEN keyword in the first matching WHEN clause of the CASE statement. (In this case, the lexical order of the WHEN clauses can determine the result of the CASE statement.) If the database server executes a GOTO statement in the statement block that follows the THEN keyword, the database server transfers program control to the specified statement label. Otherwise, the database server executes the next SPL or SQL statement that follows the END CASE keywords that mark the end of the current CASE statement in the SPL routine.
- If the value to which the *value\_expr* parameter evaluates does not match the literal value specified in the *constant\_expr* specification of any WHEN clause, and if the CASE statement includes an ELSE clause, the database server executes the statement block that immediately follows the ELSE keyword. If the database server executes a GOTO statement in the statement block that follows the ELSE keyword, the database server transfers program control to the specified statement label. Otherwise, the database server executes the next SPL or SQL statement that follows the END CASE keywords that mark the end of the current CASE statement in the SPL routine.
- If the value to which the *value\_expr* parameter evaluates does not match the literal value specified in the *constant\_expr* specification of any WHEN clause, and if the CASE statement does not include an ELSE clause, the database server issues an exception, and the CASE statement fails with error -26062. Whether the SPL routine terminates or continues to execute depends on its exception-handling logic.

This implementation of the CASE statement closely resembles that of HCL Informix® Parallel Server, except that HCL Informix® Parallel Server issues no error when no ELSE clause is specified and no WHEN clause matches the *value\_expr* parameter. In this case, program execution continues at the SPL or SQL statement that immediately follows the CASE statement.

The statement block that follows the THEN or ELSE keywords can include any SQL statement or SPL statement that is valid in a statement block of an SPL routine. For more information, see [Statement Block on page 1522](#).

## Evaluating the value expression in a CASE statement

The database server calculates the value of the *value\_expr* parameter only once, at the start of execution of the CASE statement. If the expression specified in that parameter contains one or more SPL variables, and the value of any of these variables subsequently changes in one of the statement blocks within the CASE statement, the database server does not recalculate the value of the *value\_expr* parameter. For this reason, any change in the value of variables specified in the *value\_expr* parameter has no effect on the branch taken by the CASE statement.

## Examples of CASE statements

In the following example, the CASE statement initializes one of a set of SPL variables (named **j**, **k**, **l**, and **m**) to the value of an SPL variable named **x**, depending on the value of another SPL variable named **i**:

```
CASE i
  WHEN 1 THEN LET j = x;
  WHEN 2 THEN LET k = x;
  WHEN 3 THEN LET l = x;
  WHEN 4 THEN LET m = x;
  ELSE
    RAISE EXCEPTION 100; --invalid value
END CASE;
```

Here each WHEN clause specifies a literal integer as its constant expression, under the assumption that the value expression has a numeric data type. (If these literal values had been delimited by quotation marks, the database server would treat them as character values.)

The following example includes a test for NULL in a WHEN clause, where the value expression and constant expression data types are CHAR(1):

```
CREATE PROCEDURE case_proc( )
RETURNING CHAR(1);
DEFINE grade CHAR(1);
LET grade = 'D';
CASE grade
  WHEN 'A' THEN LET grade = 'a';
  WHEN 'B' THEN LET grade = 'b';
  WHEN 'C' THEN LET grade = 'c';
  WHEN NULL THEN LET grade = 'z';
  ELSE LET grade = 'd';
END CASE;
RETURN grade;
END PROCEDURE;
```

## Related statement

[IF on page 1114](#)

## CONTINUE

Use the CONTINUE statement to start the next iteration of the innermost FOR, LOOP, WHILE, or FOREACH loop.

### Syntax

#### CONTINUE

#### FOR FOREACH LOOP WHILE

```
;
```

### Usage

When control of execution passes to a CONTINUE statement, the SPL routine skips the rest of the statements in the innermost loop of the specified type. Execution continues at the top of the loop with the next iteration.

In the following example, the **loop\_skip** function inserts values 3 through 15 into the table **testtable**. The function also returns values 3 through 9 and 13 through 15 in the process. The function does not return the value 11 because it encounters the CONTINUE FOR statement. The CONTINUE FOR statement causes the function to skip the RETURN WITH RESUME statement:

```
CREATE FUNCTION loop_skip()
RETURNING INT;
DEFINE i INT;
...
FOR i IN (3 TO 15 STEP 2)
  INSERT INTO testtable values(i, null, null);
  IF i = 11
```

```
        CONTINUE FOR;  
    END IF;  
    RETURN i WITH RESUME;  
END FOR;  
  
END FUNCTION;
```

Just as with the EXIT statement, ([EXIT on page 1101](#)), in FOREACH statements and in FOR or WHILE statements that do not include the LOOP keyword, the FOR, WHILE, or FOREACH keyword must immediately follow the CONTINUE keyword to specify the type of loop. Errors are generated if the specified type of loop does not match the context in which the CONTINUE statement is issued.

In the LOOP, FOR LOOP, and WHILE LOOP statements, whether labeled or unlabeled, a keyword indicating the type of loop is optional after the CONTINUE keyword, but Informix® issues an error if you specify a keyword that does not correspond to the type of loop.

## DEFINE

Use the DEFINE statement to declare local variables that an SPL routine uses, or to declare global variables that can be shared by several SPL routines.

**Syntax****DEFINE****GLOBAL**, *SPL\_var**data\_type***DEFAULT**Default Value<sup>478</sup>**REFERENCES****BYTE TEXT****DEFAULT NULL**, *SPL\_var**data\_type***REFERENCES****BYTE TEXT****LIKE***view synonym table**.column***PROCEDURE****BLOB CLOB**Subset of Complex Data Types<sup>479</sup>*distinct\_type opaque\_type*

;

| Element                     | Description                       | Restrictions  | Syntax                                  |
|-----------------------------|-----------------------------------|---|---|
| <i>column</i>               | Column name                       | Must already exist in the <i>table</i> or <i>view</i>                             | <a href="#">Identifier on page 1456</a> |
| <i>data_type</i>            | Type of <i>SPL_var</i>            | See <a href="#">Declaring Global Variables on page 1092</a>                       | <a href="#">Data Type on page 1163</a>  |
| <i>distinct_type</i>        | A distinct type                   | Must already be defined in the database   | <a href="#">Data Type on page 1163</a>  |
| <i>opaque_type</i>          | An opaque type                    | Must already be defined in the database   | <a href="#">Data Type on page 1163</a>  |
| <i>SPL_var</i>              | New SPL variable                  | Must be unique within statement block   | <a href="#">Identifier on page 1456</a> |
| <i>synonym, table, view</i> | Name of a table, view, or synonym | Synonym and the table or view to which it points must exist when DEFINE is issued | <a href="#">Identifier on page 1456</a> |

**Usage**

The DEFINE statement is not an executable statement. The DEFINE statement must appear after the routine header and before any other statements. If you declare a local variable (by using DEFINE without the GLOBAL keyword), its scope of

478. See [Default Value on page 1093](#)

479. See [Subset of Complex Data Types on page 1096](#)

reference is the statement block in which it is defined. You can use the variable within the statement block. Another variable outside the statement block with a different definition can have the same name.

A variable with the GLOBAL keyword is global in scope and is available outside the statement block and to other SPL routines. Global variables can be any built-in data type except BIGSERIAL, BLOB, BYTE, CLOB, SERIAL, SERIAL8, or TEXT. Local variables can be any built-in data type except BIGSERIAL, BYTE, SERIAL, SERIAL8, or TEXT. If *column* is of the BIGSERIAL, SERIAL, or SERIAL8 data type, declare a BIGINT, INT, or INT8 variable to store its value.

Declaring the names of SQL keywords or the identifiers of other database objects as SPL variables can produce errors or unexpected results in some contexts. For discussions of some potential problems of name conflicts that involve SPL variables, see the related concepts below.

[Using CURRENT, DATETIME, INTERVAL, and NULL in INSERT on page 1467](#)

## Referencing TEXT and BYTE Variables

The REFERENCES keyword lets you use BYTE and TEXT variables. These do not contain the actual data but are pointers to the data. The REFERENCES keyword indicates that the SPL variable is just a pointer. You can use BYTE and TEXT variables exactly as you would use any other variable in SPL.

## Redeclaration or Redefinition

If you define the same variable twice in the same statement block, you receive an error. You can redefine a variable within a nested block, in which case it temporarily hides the outer declaration. This example produces an error:

```
CREATE PROCEDURE example1()
  DEFINE n INT; DEFINE j INT;
  DEFINE n CHAR (1);  -- redefinition produces an error
```

Redeclaration is valid in the following example. Within the nested statement block, **n** is a character variable. Outside the block, **n** is an integer variable.

```
CREATE PROCEDURE example2()
  DEFINE n INT; DEFINE j INT;
  ...
  BEGIN
    DEFINE n CHAR (1);  -- character n masks global integer variable
    ...
  END;
```

## Declaring Global Variables

Use the following syntax for declaring global variables:

```

DEFINEGLOBAL
, SPL_var
data_typeDEFAULT
Default Value480
REFERENCES
BYTE TEXT
DEFAULT NULL
;

```

| Element          | Description            | Restrictions  | Syntax                                  |
|------------------|------------------------|---|---|
| <i>data_type</i> | Type of <i>SPL_var</i> | See <a href="#">Declaring Global Variables on page 1092</a> . | <a href="#">Data Type on page 1163</a>  |
| <i>SPL_var</i>   | New SPL variable       | Must be unique within statement block                         | <a href="#">Identifier on page 1456</a> |

The GLOBAL keyword indicates that the variables that follow have a scope of reference that includes all SPL routines that run in a given DB-Access or SQL administration API session. The data types of these variables must match the data types of variables in the *global environment*. The global environment is the memory that is used by all the SPL routines that run in a given DB-Access or SQL administration API session. The values of global variables are stored in memory.

SPL routines that are running in the current session share global variables. Because the database server does not save global variables in the database, the global variables do not remain when the current session closes.

The first declaration of a global variable establishes the variable in the global environment; subsequent global declarations simply bind the variable to the global environment and establish the value of the variable at that point.

The following example shows two SPL procedures, **proc1** and **proc2**; each has defined the global variable **gl\_out**:

- SPL procedure **proc1**

```

CREATE PROCEDURE proc1()
...
DEFINE GLOBAL gl_out INT DEFAULT 13;
...
LET gl_out = gl_out + 1;
END PROCEDURE;

```

- SPL procedure **proc2**

```

CREATE PROCEDURE proc2()
...
DEFINE GLOBAL gl_out INT DEFAULT 23;

```

480. See [Default Value on page 1093](#)

```

DEFINE tmp INT;
...
LET tmp = gl_out
END PROCEDURE;

```

If **proc1** is called first, **gl\_out** is set to 13 and then incremented to 14. If **proc2** is then called, it sees that **gl\_out** is already defined, so the default value of 23 is not applied. Then, **proc2** assigns the existing value of 14 to **tmp**. If **proc2** had been called first, **gl\_out** would have been set to 23, and 23 would have been assigned to **tmp**. Later calls to **proc1** would not apply the default of 13.

Databases of different database server instances do not share global variables, but all the databases of the same database server instance can share global SPL variables in a single session. The database server and any application development tools, however, do not share global variables.

## Default Value

Global variables can have literal, NULL, or system constant default values.

Default Value

Literal Number<sup>481</sup>

Quoted String<sup>482</sup>

Literal Interval<sup>483</sup>

Literal Datetime<sup>484</sup>

**CURRENT SYSDATE**

DATETIME Field Qualifier<sup>485</sup>

**CURRENT\_USER DBSERVERNAME SITENAME TODAY USER NULL**

If you specify a default value, the global variable is initialized with the specified value.

## CURRENT

**CURRENT** is a valid default only for a DATETIME variable. If the YEAR TO FRACTION(3) is its declared precision, no qualifier is needed. Otherwise, you must specify the same DATETIME qualifier when **CURRENT** is the default, as in the following example of a DATETIME variable:

```

DEFINE GLOBAL d_var DATETIME YEAR TO MONTH
DEFAULT CURRENT YEAR TO MONTH;

```

481. See [Literal Number on page 1419](#)

482. See [Quoted String on page 1424](#)

483. See [Literal INTERVAL on page 1418](#)

484. See [Literal DATETIME on page 1414](#)

485. See [DATETIME Field Qualifier on page 1191](#)

## SYSDATE

**SYSDATE** is a valid default only for a DATETIME variable. If the YEAR TO FRACTION(5) is the declared precision of the variable, no qualifier is needed. Otherwise, you must specify the same DATETIME qualifier when **SYSDATE** is the default, as in the following example of a DATETIME variable:

```
DEFINE GLOBAL dt_var DATETIME YEAR TO DAY
    DEFAULT SYSDATE YEAR TO DAY;
```

## USER

If you use the value that **USER**, or its synonym **CURRENT\_USER**, returns as the default, the variable must be defined as a CHAR, VARCHAR, NCHAR, or NVARCHAR data type. It is recommended that the length of the variable be at least 32 bytes. You risk getting an error message during INSERT and ALTER TABLE operations if the length of the variable is too small to store the default value.

## TODAY

If you use **TODAY** as the default, the variable must be a DATE value. (See [Constant Expressions on page 1235](#) for descriptions of **TODAY** and of the other system constants that can appear in the Default Value clause.)

## BYTE and TEXT

The only default value valid for a BYTE or TEXT variable is NULL. The following example defines a TEXT global variable that is called **l\_blob**:

```
CREATE PROCEDURE use_text()
    DEFINE i INT;
    DEFINE GLOBAL l_blob REFERENCES TEXT DEFAULT NULL;
    ...
END PROCEDURE
```

Here the REFERENCES keyword is required, because the DEFINE statement cannot declare a BYTE or TEXT data type directly; the **l\_blob** variable is a pointer to a TEXT value that is stored in the global environment.

## SITENAME or DBSERVERNAME

If you use the SITENAME or DBSERVERNAME keyword as the default, the variable must be a CHAR, VARCHAR, NCHAR, NVARCHAR, or LVARCHAR data type. Its default value is the name of the database server at runtime. It is recommended that the size of the variable be at least 128 bytes long. You risk getting an error message during INSERT and ALTER TABLE operations if the length of the variable is too small to store the default value.

The following example uses the SITENAME keyword to specify a default value. This example also initializes a global BYTE variable to NULL:

```
CREATE PROCEDURE gl_def()
    DEFINE GLOBAL gl_site CHAR(200) DEFAULT SITENAME;
    DEFINE GLOBAL gl_byte REFERENCES BYTE DEFAULT NULL;
    ...
END PROCEDURE
```

## Declaring Local Variables

A *local variable* has as its scope of reference the routine in which it is declared. If you omit the GLOBAL keyword, any variables declared in the DEFINE statement are local variables, and are not visible in other SPL routines.

For this reason, different SPL routines that declare local variables of the same name can run without conflict in the same DB-Access or SQL administration API session.

If a local variable and a global variable have the same name, the global variable is not visible within the SPL routine where the local variable is declared. (In all other SPL routines, only the global variable is in scope.)

The following DEFINE statement syntax is for declaring local variables:

### DEFINE

*, SPL\_var*

*data\_type*

### REFERENCES

### BYTE TEXT

### LIKE

*view synonym table*

*.column*

### PROCEDURE

### BLOB CLOB

Subset of Complex Data Types<sup>486</sup>

*distinct\_type opaque\_type*

;

| Element                     | Description                       | Restrictions   | Syntax  |
|-----------------------------|-----------------------------------|--|---|
| <i>column</i>               | Column name                       | Must already exist in the <i>table</i> or <i>view</i>  | <a href="#">Identifier on page 1456;</a>          |
| <i>data_type</i>            | Type of <i>SPL_var</i>            | Cannot be BIGSERIAL, BYTE, SERIAL, SERIAL8, or TEXT  | <a href="#">Data Type on page 1163</a>            |
| <i>distinct_type</i>        | A distinct type                   | Must already be defined in the database  | <a href="#">Identifier on page 1456</a>           |
| <i>opaque_type</i>          | An opaque type                    | Must already be defined in the database  | <a href="#">Identifier on page 1456</a>           |
| <i>SPL_var</i>              | New SPL variable                  | Must be unique within statement block  | <a href="#">Identifier on page 1456;</a>          |
| <i>synonym, table, view</i> | Name of a table, view, or synonym | Synonym and the table or view to which it points must already exist when the statement is issued | <a href="#">Database Object Name on page 1450</a> |

486. See [Subset of Complex Data Types on page 1096](#)

Local variables do not support default values. The following example shows some typical definitions of local variables:

```
CREATE PROCEDURE def_ex()
  DEFINE i INT;
  DEFINE word CHAR(15);
  DEFINE b_day DATE;
  DEFINE c_name LIKE customer.fname;
  DEFINE b_text REFERENCES TEXT;
END PROCEDURE
```

## Subset of Complex Data Types

To store one or more data values in a complex data type, the DEFINE statement can declare a local SPL variable as a collection of type SET, MULTISET, or LIST, with elements of a specified type, or as a generic COLLECTION. The DEFINE statement can also declare a local SPL variable as a named or an unnamed ROW type with an ordered set of fields, or as a generic ROW type.

Complex Data Types (Subset)

### COLLECTION

#### SET MULTISET LIST

(

*data\_type*

#### SET MULTISET LIST

(*data\_type*NOT NULL)

NOT NULL)

*row*

### ROW

(

, *field**data\_type*

)

| Element          | Description   | Restrictions  | Syntax                                  |
|------------------|---|---|---|
| <i>data_type</i> | Data type of collection elements, or of fields in an unnamed ROW type | Must match the data type of the values that the variable will store. Cannot be BIGSERIAL, BLOB, BYTE, CLOB, SERIAL, SERIAL8, or TEXT. | <a href="#">Data Type on page 1163</a>  |
| <i>field</i>     | Field of an unnamed ROW   | If you specify no <i>field</i> list, the generic ROW variable can store data of any ROW type  | <a href="#">Identifier on page 1456</a> |
| <i>row</i>       | Named ROW data type   | Must exist in the database  | <a href="#">Identifier on page 1456</a> |

### Example of a named ROW type variable

The following statement registers in the database a named ROW data type that can store two non-NULL integer values, and declares `two_whole_numbers_t` as its identifier:

```
CREATE ROW TYPE IF NOT EXISTS
  two_whole_numbers_t( x INT NOT NULL, y INT NOT NULL);
```

Because this CREATE ROW TYPE statement specifies no supertype, the new named ROW type inherits no fields from any existing ROW type hierarchy.

This DEFINE statement declares `numbers` as an SPL variable whose data type is the `two_whole_numbers_t` named ROW type:

```
DEFINE numbers two_whole_numbers_t; -- named ROW type
```

In the statement above, the name of this ROW type identifies the structure of the `numbers` variable as having two fields of type INT that can store only non-NULL values.

### Example of a generic ROW type variable

The next example assigns to the variable `whatever` a generic ROW data type, without field declarations:

```
DEFINE whatever ROW; -- generic ROW type
```

If an SPL function included both of these DEFINE statements, the `numbers` variable could return two integers as the result of the SPL routine, but the results cannot be returned to the calling context by the `whatever` variable.

#### Important:

Generic ROW and generic COLLECTION types are not supported as return data types of SPL functions. In the example above, the SPL routine must cast the fields of the generic ROW variable `whatever` into specific SQL data types.

Similarly, if elements of a generic COLLECTION variable store the routine results, those values must be cast into specific SQL data types that the SPL routine can return.

## Declaring Collection Variables

A local variable of type COLLECTION, SET, MULTISSET, or LIST can hold a collection of values fetched from the database. You cannot define a collection variable as global (with the GLOBAL keyword) or with a default value.

A variable declared with the keyword COLLECTION is an untyped (or generic) collection variable that can hold a collection of any data type.

A variable declared as type SET, MULTISSET, or LIST is a *typed collection variable*. It can hold a collection of its specified data type only.

You must use the NOT NULL keywords when you define the elements of a typed collection variable, as in the following examples:

```
DEFINE a SET ( INT NOT NULL );

DEFINE b MULTISSET ( ROW ( b1 INT,
                          b2 CHAR(50)
                        ) NOT NULL );

DEFINE c LIST( SET( INTEGER NOT NULL ) NOT NULL );
```

With variable `c`, both the INTEGER values in the SET and the SET values in the LIST are defined as NOT NULL.

You can define collection variables with nested complex types to hold matching nested complex type data. Any type or depth of nesting is allowed. You can nest **ROW** types within collection types, collection types within **ROW** types, collection types within collection types, **ROW** types within collection and **ROW** types, and so on.

If you declare a variable as **COLLECTION** type, the variable acquires varying data type declarations if it is reassigned within the same statement block, as in the following example:

```
DEFINE a COLLECTION;
LET a = setB;
...
LET a = listC;
```

In this example, **varA** is a generic collection variable that changes its data type to the data type of the currently assigned collection. The first **LET** statement makes **varA** a **SET** variable. The second **LET** statement makes **varA** a **LIST** variable.

## Declaring ROW Variables

**ROW** variables hold data from named or unnamed **ROW** types. You can define a generic **ROW** variable, a named **ROW** variable, or an unnamed **ROW** variable.

A generic **ROW** variable, defined with the **ROW** keyword, can hold data from any **ROW** type. A named **ROW** variable holds data from the named **ROW** type that you specified in the declaration of the variable.

The following statements show examples of generic **ROW** variables and named **ROW** variables:

```
DEFINE d ROW;           -- generic ROW variable

DEFINE rectv rectangle_t; -- named ROW variable
```

A named **ROW** variable holds named **ROW** types of the same type in the declaration of the variable.

To define a variable that will hold data stored in an unnamed **ROW** type, use the **ROW** keyword followed by the fields of the **ROW** type, as in:

```
DEFINE area ROW ( x int, y char(10) );
```

Unnamed **ROW** types are type-checked only by structural equivalence. Two unnamed **ROW** types are considered equivalent if they have the same number of fields, and if the fields have the same type definitions. Therefore, you could fetch either of the following **ROW** types into the variable **area** defined above:

```
ROW ( a int, b char(10) )
ROW ( area int, name char(10) )
```

**ROW** variables can have fields, just as **ROW** types have fields. To assign a value to a field of a **ROW** variable, use the qualifier notation *variableName.fieldName*, followed by an expression, as in the following example:

```
CREATE ROW TYPE rectangle_t (start point_t, length real, width real);

DEFINE r rectangle_t;
    -- Define a variable of a named ROW type
LET r.length = 45.5;
    -- Assign a value to a field of the variable
```

When you assign a value to a **ROW** variable, you can use any valid expression.

## Declaring Opaque-Type Variables

Opaque-type variables hold data retrieved from opaque data types, which you create with the CREATE OPAQUE TYPE statement. An opaque-type variable can only hold data of the same opaque type on which it is defined. The following example defines a variable of the opaque type **point**, which holds the **x** and **y** coordinates of a two-dimensional point:

```
DEFINE b point;
```

## Declaring Variables LIKE Columns

If you use the LIKE clause, the database server assigns the variable the same data type as a specified column in a table, synonym, or view.

The data types of variables that are defined as database columns are resolved at runtime; therefore, *column* and *table* do not need to exist at compile time.

You can use the LIKE keyword to declare that a variable is like a serial column. This declares:

- An INTEGER variable if the column is of the SERIAL data type
- An INT8 variable if the column is of the SERIAL8 data type
- A BIGINT variable if the column is of the BIGSERIAL data type

For example, if the column **serialcol** in the **mytab** table has the SERIAL data type, you can create the following SPL function:

```
CREATE FUNCTION func1()
DEFINE local_var LIKE mytab.serialcol;
RETURN;
END FUNCTION;
```

The variable **local\_var** is treated as an INTEGER variable.

## Defining Variables with Logical Character Semantics

When the SQL\_LOGICAL\_CHAR configuration parameter has specified for the current session) is set to 'ON' or to a value greater than 1, Informix® interprets size declarations as logical characters, rather than as bytes, in declarations of SPL variables of the following data types:

- CHAR or CHARACTER
- CHARACTER VARYING or VARCHAR
- LVARCHAR
- NCHAR
- NVARCHAR
- DISTINCT types whose base types are built-in character data types
- DISTINCT types whose base types are the previously listed data types
- ROW data type fields of any of the previously listed data types.
- Elements of these data types in LIST, MULTISSET, or SET collection data types.

Enabling logical character semantics for the database locale guarantees that sufficient storage is available for the data type to store the specified number of logical characters. The resulting size in bytes of the SPL variable is the product of the declared size of the data type multiplied by the SQL\_LOGICAL\_CHAR value, if this is 2, 3, or 4, or (if SQL\_LOGICAL\_CHAR is set to 'ON') by the number of bytes of storage that the largest logical character in the code set of the database locale requires.

If a client session connects to a database in which the SQL\_LOGICAL\_CHAR configuration parameter was enabled at the time of database creation, that setting takes effect at connection time.

DEFINE statements that use the LIKE keyword in datatype declarations create SPL variables whose data types match the schema of the column that the LIKE specification references. The SQL\_LOGICAL\_CHAR setting, if any is defined, has no effect on the size in memory of variables that DEFINE declares with the LIKE keyword.

For more information about the effect of the SQL\_LOGICAL\_CHAR setting in locales that use a multibyte code set, such as **UTF-8**, where a single logical character can require more than one byte of storage, see the description of the SQL\_LOGICAL\_CHAR configuration parameter in your . For additional information about multibyte locales and logical characters, see the *Informix® GLS User's Guide*.

## Declaring Variables as the PROCEDURE Type

The PROCEDURE keyword indicates that in the current scope, the variable is a call to a UDR.

The DEFINE statement does not support a FUNCTION keyword. Use the PROCEDURE keyword, whether you are calling a user-defined procedure or a user-defined function.

Declaring a variable as PROCEDURE type indicates that in the current statement scope, the variable is not a call to a built-in function. For example, the following statement defines **length** as an SPL routine, not as the built-in LENGTH function:

```
DEFINE length PROCEDURE;
...
LET x = length (a,b,c)
```

This definition disables the built-in LENGTH function within the scope of the statement block. You would use such a definition if you had already created a user-defined routine with the name **length**.

If you create an SPL routine with the same name as an aggregate function (SUM, MAX, MIN, AVG, COUNT) or with the name **extend**, you must qualify the routine name with the owner name.

## Declaring Variables for BYTE and TEXT Data

The keyword REFERENCES indicates that the variable does not contain a BYTE or TEXT value but is a pointer to the BYTE or TEXT value. Use the variable as though it holds the data.

The following example defines a local BYTE variable:

```
CREATE PROCEDURE use_byte()
  DEFINE i INT;
  DEFINE l_byte REFERENCES BYTE;
END PROCEDURE --use_byte
```

If you pass a variable of BYTE or TEXT data type to an SPL routine, the data is passed to the database server and stored in the root dbspace or dbspaces that the **DBSPACETEMP** environment variable specifies, if it is set. You do not need to know the location or name of the file that holds the data. BYTE or TEXT manipulation requires only the name of the BYTE or TEXT variable as it is defined in the routine.

## EXIT

The EXIT statement can terminate FOR, FOREACH, LOOP, or WHILE statements.

### Syntax

**EXIT**

**FOREACH**

**FOR LOOP WHILE**

*label*

**WHEN***condition*

;

| Element          | Description                                  | Restrictions   | Syntax                                  |
|------------------|--|--|---|
| <i>condition</i> | Loop terminates when this evaluates to TRUE. | If <i>condition</i> evaluates to FALSE, the loop continues.            | <a href="#">Condition on page 1144</a>  |
| <i>label</i>     | Label of a loop from which to exit           | Must be the label of a loop statement that includes the EXIT statement | <a href="#">Identifier on page 1456</a> |

### Usage

The EXIT statement transfers control of execution from an iterative statement, causing the innermost loop of the enclosing statement type (FOR, FOREACH, LOOP, or WHILE) to terminate. If no loop label or WHEN condition is specified, execution resumes at the first statement that follows the current FOR, FOREACH, LOOP, or WHILE statement.

### EXIT From FOREACH Statements

If the EXIT statement has the FOREACH statement as its innermost enclosing statement, the FOREACH keyword must immediately follow the EXIT keyword. The EXIT FOREACH statement unconditionally terminates the FOREACH statement, or else returns an error, if no FOREACH statement encloses the EXIT FOREACH statement.

The following program fragment includes the EXIT FOREACH statement:

```
FOREACH cursor1 FOR
  SELECT * INTO a FROM TABLE(b);
  IF a = 4 THEN
    DELETE FROM TABLE(b)
      WHERE CURRENT OF cursor1;4
    EXIT FOREACH;
  END IF;
END FOREACH;
```

## EXIT From FOR, LOOP, and WHILE Loops

If the EXIT statement is issued outside the FOREACH statement, it returns an error unless it is issued from the FOR, FOR LOOP, LOOP, WHILE LOOP, or WHILE statement as its innermost enclosing statement. In FOR or WHILE statements that do not include the LOOP keyword, the corresponding FOR or WHILE keyword is required after the EXIT keyword. Execution resumes at the first executable statement that follows the innermost loop from which the EXIT statement was issued.

The EXIT statement requires no other keyword when it is issued from the FOR LOOP, LOOP, or WHILE LOOP statement, with or without a loop label, but if you include the FOR, LOOP, or WHILE keyword after the EXIT keyword, that keyword must correspond to the type of loop from which the EXIT statement is issued.

If the EXIT keyword is followed by the identifier of a loop label, and no *condition* is specified, execution resumes at the first executable statement that follows the FOR, FOR LOOP, LOOP, WHILE LOOP, or WHILE statement whose label is specified. This enables the EXIT statement to exit from nested loops, if an outer loop is labeled.

If a WHEN *condition* follows the EXIT or EXIT *label* specification, EXIT has no effect unless the *condition* is true. If the condition is true, execution resumes after the labeled loop, or after the innermost loop, if no *label* is specified.

If the database server cannot find the specified loop or loop label, the EXIT statement fails. If EXIT is issued outside any FOR, FOREACH, LOOP, or WHILE statement, it generates errors.

The following example uses an EXIT FOR statement. In the FOR loop, when *j* becomes 6, the IF condition *i = 5* in the WHILE loop is true. The FOR loop stops executing, and the SPL procedure continues at the next statement outside the FOR loop (in this case, the END PROCEDURE statement). In this example, the procedure ends when *j* equals 6:

```
CREATE PROCEDURE ex_cont_ex()
  DEFINE i,s,j, INT;
  FOR j = 1 TO 20
    IF j > 10 THEN
      CONTINUE FOR;
    END IF
    LET i,s = j,0;
    WHILE i > 0
      LET i = i -1;
      IF i = 5 THEN
        EXIT FOR;
      END IF
    END WHILE
  END FOR
END PROCEDURE;
```

The following program fragment shows two conditional EXIT statements in a labeled WHILE LOOP statement that is nested within another labeled LOOP statement:

```
<<outer>>
LOOP
LET x = x+1;
  <<inner>>
  WHILE ( i >10 ) LOOP
    LET x = x+1;
    EXIT inner WHEN x = 2;
    EXIT outer WHEN x > 3;
  END LOOP inner;
LET x = x+1;
END LOOP outer;
```

When the `x=2` condition is true, the `EXIT inner` statement transfers control to the LET statement that follows the loop whose label is `inner`. When the `x>3` condition is true, the `EXIT outer` statement terminates execution of the `outer` loop.

| <i>loop_var</i>   | Variable that determines how many times the loop executes   | Must be defined and in scope within this statement block  | <a href="#">Identifier on page 1456</a> |
| <i>right_expr</i> | Ending expression in the range  | Same as for <i>left_expr</i>  | <a href="#">Expression on page 1193</a> |

## Usage

The database server evaluates all expressions before the FOR statement executes. If one or more of the expressions are variables whose values change during the loop, the change has no effect on the iterations of the loop.

You can use the output from a SELECT statement as the *expression*.

The FOR loop terminates when *loop\_var* is equal to the values of each element in the expression list or range in succession, or when it encounters an EXIT FOR statement. An error is issued, however, if an assignment within the body of the FOR statement attempts to modify the value of *loop\_var*.

The size of *right\_expr* relative to *left\_expr* determine whether the range is stepped through by positive or by negative increments:

- The increments are positive if *left\_expr* < *right\_expr*.
- The increments are negative if *left\_expr* > *right\_expr*.

If you specify no *increment\_expr*, the default size of each step is 1, with a positive or negative sign determined by the rules above.

## Using the TO Keyword to Define a Range

The TO keyword implies a range operator. The range is defined by *left\_expression* and *right\_expression*, and the STEP *increment\_expr* option implicitly sets the number of increments. If you use the TO keyword, *loop\_var* must be an INT or SMALLINT data type.

The next example shows two equivalent FOR statements. Each uses the TO keyword to define a range. The first uses the IN keyword, and the second uses an equal sign (=). Each statement causes the loop to execute five times:

```
FOR index_var IN (12 TO 21 STEP 2)
  -- statement block
END FOR;
```

```
FOR index_var = 12 TO 21 STEP 2
  -- statement block
END FOR;
```

If you omit the STEP option, the database server gives *increment\_expr* the value of `-1` if *right\_expression* is less than *left\_expression*, or `+1` if *right\_expression* is more than *left\_expression*. If *increment\_expr* is specified, it must be negative if *right\_expression* is less than *left\_expression*, or positive if *right\_expression* is more than *left\_expression*.

The two statements in the following example are equivalent. In the first statement, the STEP increment is explicit. In the second statement, the STEP increment is implicitly `1`:

```
FOR index IN (12 TO 21 STEP 1)
  -- statement block
END FOR;

FOR index = 12 TO 21
  -- statement block
END FOR;
```

The database server initializes the value of *loop\_var* to the value of *left\_expression*. In subsequent iterations, the server adds *increment\_expr* to the value of *loop\_var* and checks *increment\_expr* to determine whether the value of *loop\_var* is still between *left\_expression* and *right\_expression*. If so, the next iteration occurs. Otherwise, an exit from the loop takes place. Or, if you specify another range, the variable takes on the value of the first element in the next range.

## Specifying Two or More Ranges in a Single FOR Statement

The following example shows a statement that traverses a loop forward and backward and uses different increment values for each direction:

```
FOR index_var IN (15 to 21 STEP 2, 21 to 15 STEP -3)
  -- statement body
END FOR;
```

## Using an Expression List as the Range

The database server initializes the value of *loop\_var* to the value of the first expression specified. In subsequent iterations, *loop\_var* takes on the value of the next expression. When the database server has evaluated the last expression in the list and used it, the loop stops.

The expressions in the IN list do not need to be numeric values, as long as you do not use range operators in the IN list. The following example uses a character expression list:

```
FOR c IN ('hello', (SELECT name FROM t), 'world', v1, v2)
  INSERT INTO t VALUES (c);
END FOR;
```

The following FOR statement shows the use of a numeric expression list:

```
FOR index IN (15,16,17,18,19,20,21)
  -- statement block
END FOR;
```

## Mixing Range and Expression Lists in the Same FOR Statement

If *loop\_var* is an INT or SMALLINT value, you can mix ranges and expression lists in the same FOR statement. The following example shows a mixture that uses an integer variable. Values in the expression list include the value that is returned from a SELECT statement, a sum of an integer variable and a constant, the values that are returned from an SPL function named **p\_get\_int**, and integer constants:

```
CREATE PROCEDURE for_ex ()
  DEFINE i, j INT;
  LET j = 10;
  FOR i IN (1 TO 20, (SELECT c1 FROM tab WHERE id = 1),
           j+20 to j-20, p_get_int(99),98,90 to 80 step -2)
    INSERT INTO tab VALUES (i);
  END FOR;
END PROCEDURE;
```

## Specifying a Labelled FOR Loop

### About this task

To create a labeled FOR loop, declare a loop label before the initial FOR keyword, and repeat the label after the END FOR keywords, as in this example:

```
CREATE PROCEDURE ex_cont_ex()
  DEFINE i,s,j, INT;
  <<for_lab>>
  FOR j = 1 TO 20
    IF j > 10 THEN
      CONTINUE FOR;
    END IF
    LET i,s = j,0;
    WHILE i > 0
      LET i = i -1;
      IF i = 5 THEN
        EXIT for_lab;
      END IF
    END WHILE
  END FOR for_lab
END PROCEDURE;
```

Here the `EXIT for_lab` statement has the same effect that the `EXIT` or `EXIT FOR` keywords would have, terminating both the FOR loop and the routine. In this example, the statement that includes the `EXIT for_lab` statement has the same effect that `EXIT for_lab WHEN i = 5` would have.

You can also label a LOOP statement that begins with a loop `<<label>>` specification that immediately precedes the initial FOR keyword. In this type of loop, the `CONTINUE LOOP`, `EXIT LOOP`, and `END LOOP` keywords replace the `CONTINUE FOR`, `EXIT FOR`, and `END FOR` keywords. Both the `LOOP` and `FOR` keywords are optional after the `CONTINUE` and `EXIT` keywords, but the `END LOOP` keywords are required in SPL loop statements that include the `LOOP` keyword.

You can use similar syntax to create an unlabeled loop that omits the `<<label>>` specification that immediately precedes the initial FOR keyword. In this case, you must also omit the undelimited loop label identifier that follows the `END LOOP` keywords. See the `LOOP` statement for a description and examples of these forms of labeled and unlabeled loop statements that enable you to combine FOR statement syntax, with a finite number of loop iterations, with the "loop forever" syntax of the `LOOP` statement.

**FOREACH**

Use the FOREACH statement to declare a direct cursor that can select and manipulate more than one row from a the result set of a query, or more than one element from a collection.

**Syntax**

Direct sequential cursors that the FOREACH statement of SPL can create are distinct from the dynamic cursors that the DECLARE statement of SQL can create in SPL routines. (For the syntax and usage of dynamic cursors in SPL routines, see [Declaring a Dynamic Cursor in an SPL Routine on page 484.](#))

| Element                    | Description   | Restrictions   | Syntax  |
|----------------------------|---|--|---|
| <i>cursor</i>              | Identifier that you declare here as the name of this direct cursor    | Must be unique among names of cursors, prepared statements, and SPL variables in the routine | <a href="#">Identifier on page 1456</a>           |
| <i>data_var</i>            | SPL variable in the calling routine that receives the returned values | Data type of <i>data_var</i> must be appropriate for returned value                          | <a href="#">Identifier on page 1456</a>           |
| <i>function, procedure</i> | SPL function or procedure to execute                                  | Function or procedure must exist   | <a href="#">Database Object Name on page 1450</a> |
| <i>SPL_var</i>             | SPL variable that contains the name of a routine to execute           | Must be of type CHAR, VARCHAR, NCHAR, or NVARCHAR  | <a href="#">Identifier on page 1456</a>           |

## Usage

To execute a FOREACH statement, the database server takes these actions:

1. It declares and implicitly opens a direct sequential cursor.
2. It obtains the first row from the query contained within the FOREACH loop, or else the first set of values from the called routine.
3. It assigns to each variable in the variable list the value of the corresponding value from the active set that the SELECT statement or the called routine creates.
4. It executes the statement block.
5. It fetches the next row from the SELECT statement or called routine on each iteration, and it repeats steps 3 and 4.
6. It terminates the loop when it finds no more rows that satisfy the SELECT statement or called routine. It closes the direct sequential cursor when the loop terminates.

Because the statement block can contain additional FOREACH statements, cursors can be nested. No limit exists on the number of nested cursors.

An SPL routine that returns more than one row, collection element, or set of values is called a *cursor function*. An SPL routine that returns only one row or value is called a *noncursor function*.

This SPL procedure illustrates FOREACH statements with a SELECT ... INTO clause, with an explicitly named cursor, and with a procedure call:

```
CREATE PROCEDURE foreach_ex()
  DEFINE i, j INT;
  FOREACH SELECT c1 INTO i FROM tab ORDER BY 1
    INSERT INTO tab2 VALUES (i);
  END FOREACH
  FOREACH cur1 FOR SELECT c2, c3 INTO i, j FROM tab
    IF j > 100 THEN
      DELETE FROM tab WHERE CURRENT OF cur1;
      CONTINUE FOREACH;
    END IF
    UPDATE tab SET c2 = c2 + 10 WHERE CURRENT OF cur1;
  END FOREACH
  FOREACH EXECUTE PROCEDURE bar(10,20) INTO i
```

```
INSERT INTO tab2 VALUES (i);
END FOREACH
END PROCEDURE; -- foreach_ex
```

A Select cursor is closed when any of the following situations occur:

- The cursor returns no further rows.
- The cursor is a Select cursor without a HOLD specification, and a transaction completes using the COMMIT or ROLLBACK statement.
- An EXIT statement executes, which transfers control out of the FOREACH statement.
- An exception occurs that is not trapped inside the body of the FOREACH statement. (See [ON EXCEPTION on page 1124](#).)
- A cursor in the calling routine that is executing this cursor routine (within a FOREACH loop) closes for any reason.

**Note:**

The FOREACH statement cannot define a SCROLL cursor. Each FOREACH cursor is a sequential cursor, which can fetch only the next row in sequence from the active set. A cursor that FOREACH defines can read through the active set only once each time it is opened.

## Using a SELECT ... INTO Statement

As indicated in the diagram for [FOREACH on page 1107](#), not all clauses and options of the SELECT statement are available for you to use in a FOREACH statement. The SELECT statement in the FOREACH statement must include the INTO clause. It can also include UNION and ORDER BY clauses, but it cannot use the INTO TEMP clause. For a complete description of SELECT syntax and usage, see [SELECT statement on page 768](#). The data type and count of each variable in the variable list must match each value that the `SELECT ... INTO` statement returns.

The database server issues an error if you include a semicolon ( ; ) within the FOREACH statement to terminate the `SELECT ... INTO` specification. The following program fragment, for example, fails with a syntax error:

```
CREATE DBA PROCEDURE IF NOT EXISTS shapes()

DEFINE vertexes SET( point NOT NULL );
DEFINE pnt point;
```

```

SELECT definition INTO vertexes FROM polygons
  WHERE id = 207;

FOREACH cursor1 FOR
  SELECT * INTO pnt FROM TABLE(vertexes); -- Semicolon not valid
  . . .
END FOREACH
. . .
END PROCEDURE;

```

In the example above, you can avoid this error by deleting the semicolon that immediately follows the `TABLE(vertexes)` specification.

## Using the ORDER BY Clause of the SELECT Statement

The ORDER BY clause of the SELECT statement implies that the query returns more than one row. Unless you use the DECLARE statement of SQL to define a Select cursor or a Function cursor, the database server issues an error if you specify the ORDER BY clause outside the context of a FOREACH loop to process the returned rows individually within an SPL routine.

For the syntax and usage of the DECLARE statement in SPL routines, see [Declaring a Dynamic Cursor in an SPL Routine on page 484](#).

## Using Hold Cursors

The WITH HOLD keywords specify that the cursor should remain open when a transaction closes (by being committed or by being rolled back).

## Updating or Deleting Rows Identified by Cursor Name

Specify a *cursor* name in the FOREACH statement if you intend to use the WHERE CURRENT OF *cursor* clause in UPDATE or DELETE statements that operate on the current row of *cursor* within the FOREACH loop. Although you cannot include the FOR UPDATE keywords in the SELECT ... INTO segment of the FOREACH statement, the cursor behaves like a FOR UPDATE cursor.

For a discussion of locking, see the section on [Locking with an Update Cursor on page 474](#). For a discussion of isolation levels, see the description of [SET ISOLATION statement on page 974](#).

## Using Collection Variables

The FOREACH statement allows you to declare a cursor for an SPL collection variable. Such a cursor is called a *Collection cursor*. Use a collection variable to access the elements of a collection (SET, MULTISSET, LIST) column. Use a cursor when you want to access one or more elements in a collection variable.

The following excerpt from an SPL routine shows how to fill a collection variable and then how to use a cursor to access individual elements:

```

DEFINE a SMALLINT;
DEFINE b SET(SMALLINT NOT NULL);
SELECT numbers INTO b FROM table1 WHERE id = 207;
FOREACH cursor1 FOR

```

```
SELECT * INTO a FROM TABLE(b);
...
END FOREACH;
```

In this example, the SELECT statement selects one element at a time from the collection variable **b** into the element variable **a**. The projection list is an asterisk, because the collection variable **b** contains a collection of built-in types. The variable **b** is used with the TABLE keyword as a Collection-Derived Table. For more information, see [Collection-Derived Table on page 1436](#).

The next example also shows how to fill a collection variable and then how to use a cursor to access individual elements. This example, however, uses a list of ROW-type fields in its projection list:

```
DEFINE employees employee_t;
DEFINE n VARCHAR(30);
DEFINE s INTEGER;

SELECT emp_list into employees FROM dept_table
WHERE dept_no = 1057;
FOREACH cursor1 FOR
  SELECT name,salary
  INTO n,s FROM TABLE( employees ) AS e;
...
END FOREACH;
```

Here the collection variable **employees** contains a collection of ROW types. Each ROW type contains the fields **name** and **salary**. The collection query selects one name and salary combination at a time, placing **name** into **n** and **salary** into **s**. The AS keyword declares **e** as an alias for the collection-derived table **employees**. The alias exists as long as the SELECT statement executes.

## Restrictions on collection cursors

When you use a Collection cursor to fetch individual elements from a collection variable, the FOREACH statement has the following restrictions:

- It cannot contain the WITH HOLD keywords.
- It must contain a restricted SELECT statement in the FOREACH loop.

In addition, the SELECT statement that you associate with the Collection cursor has the following restrictions:

- Its general structure is SELECT INTO FROM TABLE. The statement selects one element at a time from a collection variable specified after the TABLE keyword into another variable called an *element variable*.
- It cannot contain an expression in the Projection list.
- It cannot include the following clauses or options: WHERE, GROUP BY, ORDER BY, HAVING, INTO TEMP, and WITH REOPTIMIZATION.
- The data type of the element variable must be the same as the element type of the collection.
- The data type of the element variable can be any opaque, distinct, or collection data type, or any built-in data type except BIGSERIAL, BLOB, BYTE, CLOB, SERIAL, SERIAL8, or TEXT.

- If the collection contains opaque, distinct, built-in, or collection types, the projection list must be an asterisk ( \* ) symbol.
- If the collection contains ROW types, the projection list can be a list of one or more field names.

## Modifying Elements in a Collection Variable

To update an element of a collection within an SPL routine, you must first declare a cursor with the FOREACH statement.

Then, within the FOREACH loop, select elements one at a time from the collection variable, using the collection variable as a collection-derived table in a SELECT query.

When the cursor is positioned on the element to be updated, you can use the WHERE CURRENT OF clause, as follows:

- The UPDATE statement with the WHERE CURRENT OF clause updates the value in the current element of the collection variable.
- The DELETE statement with the WHERE CURRENT OF clause deletes the current element from the collection variable.

## Using Select Cursors with FOREACH

When using the FOREACH statement, if the result set from a query is to be modified, do not use this result set as an exit criterion for the FOREACH loop. For example, if the FOREACH statement declares a Select cursor that is expected to return 30 rows, but DELETE, INSERT, or UPDATE operations within the FOREACH loop modify the result set of the query, this might cause unexpected behavior. To ensure that a FOREACH loop works as intended, make sure that any Select cursor in the FOREACH statement completes its execution before you begin modifying its result set.

One way to avoid unexpected results from a FOREACH loop that performs DML operations on the rows returned by a query is to use an ORDER BY clause in the SELECT statement to materialize the result set.

## Calling a UDR in the FOREACH Loop

In general, use these guidelines for calling another UDR from an SPL routine:

- To call a user-defined procedure, use EXECUTE PROCEDURE *procedure name*.
- To call a user-defined function, use EXECUTE FUNCTION *function name* (or EXECUTE PROCEDURE *function name* if the user-defined function was created with the CREATE PROCEDURE statement).

If you use EXECUTE PROCEDURE, the database server looks first for a user-defined procedure of the name you specify. If it finds the procedure, the database server executes it. If it does not find the procedure, it looks for a user-defined function of the same name to execute. If the database server finds neither a function nor a procedure, it issues an error message. If you use EXECUTE FUNCTION, the database server looks for a user-defined function of the name you specify. If it does not find a function of that name, the database server issues an error message.

An SPL function can return zero (0) or more values or rows.

The data type and count of each variable in the variable list must match each value that the function returns.

## Related Statements

[CONTINUE on page 1088](#), [EXIT on page 1101](#), [FOR on page 1103](#), [LOOP on page 1120](#), [WHILE on page 1136](#)

## GOTO

Use the GOTO statement to transfer control of program execution to the statement that has a specified statement label.

### Syntax

**GOTO***label*

;

| Element      | Description                          | Restrictions                                    | Syntax                                  |
|--------------|--------------------------------------|---|---|
| <i>label</i> | Name of the loop label for this loop | Must be unique among labels in this SPL routine | <a href="#">Identifier on page 1456</a> |

### Usage

The GOTO statement branches to a statement label unconditionally. The statement label must be unique within its scope and must precede an executable statement. When successfully executed, the GOTO statement transfers control to the labeled statement or statement block.

In the following program fragment, the **jump\_back** function transfers control to a LET statement that has the statement label **back** if the value of variable **j** is greater than 100.

```
CREATE FUNCTION jump_back()
  RETURNING INT;
  DEFINE i,j INT;
  ...
  <<back>>
  LET j = j + i
  FOR i IN (1 TO 52 STEP 5)
    IF i < 11 THEN
      LET j = j + 3
      CONTINUE FOR;
    END IF;
    IF j > 100 THEN
      GOTO back
    END IF;
    RETURN j WITH RESUME;
  END FOR;
END FUNCTION;
```

The GOTO statement is not valid in an ON EXCEPTION statement block.

The identifier of the statement label that the GOTO statement references must exist in the database, must be unique among statement labels and loop labels the SPL routine, and must be within a scope that the GOTO statement can reach.

### Example

## Related Statements

[<< Label >> statement on page 1081](#)

## IF

Use the IF statement to create a logical branch within an SPL routine.

### Syntax

#### IF

Condition<sup>492</sup>

#### THEN

IF Statement List<sup>493</sup>

#### ELIF

Condition<sup>492</sup>

#### THEN

IF Statement List<sup>493</sup>

#### ELSE

IF Statement List<sup>493</sup>

#### END IF

;

### Usage

The database server processes the IF statement by the following steps:

1. If the condition that follows the IF keyword is true, any statements that follow the first THEN keyword of the IF statement execute, and the IF statement terminates.
2. If the result of the initial IF condition is false, but an ELIF clause exists, the database server evaluates the condition that follows the ELIF keyword.
3. If the result of the ELIF condition is true, any statements that follow the THEN keyword of the ELIF clause execute, and the IF statement terminates.
4. If the result of the condition in the first ELIF clause is also false, but one or more additional ELIF clauses exist, the database server evaluates the condition in the next ELIF clause, and proceeds as in the previous step if it is true. If it is false, the database server evaluates the condition in successive ELIF clauses, until it finds a condition that is true, in which case it executes the statement list that follows the THEN keyword of that ELIF clause, and the IF statement terminates.
5. If no condition in the IF statement is true, but the ELSE clause exists, statements that follow the ELSE keyword execute, and the IF statement terminates.
6. If none of the conditions in the IF statement are true, and no ELSE clause exists, the IF statement terminates without executing any statement list.

492. See [Condition on page 1144](#)

493. See [IF Statement List on page 1116](#)

## ELIF Clause

Use the ELIF clause to specify one or more additional conditions to evaluate. If the IF condition is false, the ELIF condition is evaluated. If the ELIF condition is true, the statements that follow the THEN keyword in the ELIF clause execute.

If no statement follows the THEN keyword of the ELIF clause when the ELIF condition is true, program control passes from the IF statement to the next statement.

## ELSE Clause

The ELSE clause executes if no true previous condition exists in the IF clause or any of the ELIF clauses.

In the following example, the SPL function uses an IF statement with both an ELIF clause and an ELSE clause. The IF statement compares two strings.

The function displays `1` to indicate that the first string comes before the second string alphabetically, or `-1` if the first string comes after the second string alphabetically. If the strings are the same, a zero (0) is returned.

```
CREATE FUNCTION str_compare (str1 CHAR(20), str2 CHAR(20))
  RETURNING INT;
  DEFINE result INT;
  IF str1 > str2 THEN LET result =1;
    ELIF str2 > str1 THEN LET result = -1;
    ELSE LET result = 0;
  END IF
  RETURN result;
END FUNCTION -- str_compare
```

## Conditions in an IF Statement

Just as in the WHILE statement, if any expression in the *condition* evaluates to NULL, then the condition cannot be true, unless you are explicitly testing for NULL using the IS NULL operator. The following rules summarize NULL values in conditions:

1. If the expression **x** evaluates to NULL, then **x** is not true by definition. Furthermore, NOT (**x**) is also not true .
2. IS NULL is the only operator that can return true for **x**. That is, **x** IS NULL is true, and **x** IS NOT NULL is not true.

If an expression in the condition has an UNKNOWN value from an uninitialized SPL variable, the statement terminates and raises an exception.

You can specify a trigger-type Boolean operator (DELETING, INSERTING, SELECTING, or UPDATING) as a condition in an IF statement only within a trigger routine.

## IF Statement List

IF Statement List

**BEGIN**

Statement Block<sup>494</sup>

**END**

Subset of SPL Statements<sup>495</sup>

Subset of SQL Statements<sup>496</sup>

;

## Subset of SPL Statements Allowed in the IF Statement List

You can use any of the following SPL statements in the IF statement list:

- <<Label >>
- CALL
- CASE
- CONTINUE
- EXIT
- FOR
- FOREACH
- GOTO
- IF
- LET
- LOOP
- RAISE EXCEPTION
- RETURN
- SYSTEM
- TRACE
- WHILE

The Subset of SPL Statements syntax diagram for the [IF Statement List on page 1116](#) refers to the SPL statements that are listed above.

## SQL Statements Not Valid in an IF Statement

The Subset of SQL Statements element in the syntax diagram for the [IF Statement List on page 1116](#) refers to all SQL statements, except for the following SQL statements, which are not valid in the IF statement list.

- ALLOCATE DESCRIPTOR
- CLOSE DATABASE

494. See [Statement Block on page 1522](#)

495. See [Subset of SPL Statements Allowed in the IF Statement List on page 1116](#)

496. See [SQL Statements Not Valid in an IF Statement on page 1116](#)

- CONNECT
- CREATE DATABASE
- CREATE PROCEDURE
- DATABASE
- DEALLOCATE DESCRIPTOR
- DESCRIBE
- DISCONNECT
- DROP DATABASE
- EXECUTE
- FLUSH
- GET DESCRIPTOR
- GET DIAGNOSTICS
- INFO
- LOAD
- OUTPUT
- PUT
- RENAME DATABASE
- SET AUTOFREE
- SET CONNECTION
- SET DESCRIPTOR
- UNLOAD
- WHENEVER

You can use a SELECT statement only if you use the INTO TEMP clause to store the result set of the SELECT statement in a temporary table.

### **Related Statements**

[WHILE on page 1136](#)

## **LET**

Use the LET statement to assign values to variables or to call a user-defined SPL routine and assign the returned value or values to SPL variables.

**Syntax****LET**

```

, SPL_var
=
,
function(
, Argument497
)
, Expression498
(
, SELECT Statement499
)
;

```

| Element         | Description   | Restrictions  | Syntax                                   |
|-----------------|---|---|--|
| <i>function</i> | SPL function to be invoked  | Must exist in the database                              | <a href="#">Identifier on page 1456</a>  |
| <i>SPL_var</i>  | SPL variable to receive a value that the <i>function</i> , expression, or query returns | Must be defined and in scope within the statement block | <a href="#">Identifier on page 1456;</a> |

**Usage**

The LET statement can assign a value returned by an expression, function, or query to an SPL variable. At runtime, the value to be assigned is calculated first. The resulting value is cast to the data type of *SPL\_var*, if possible, and the assignment occurs. If conversion is not possible, an error occurs, and the value of the variable remains undefined. (A LET operation that assigns a single value to a single SPL variable is called a *simple assignment*.)

A *compound assignment* assigns multiple expressions to multiple SPL variables. The data types of expressions in the expression list do not need to match the data types of the corresponding variables in the variable list, because the database server automatically converts the data types. (For a detailed discussion of casting, see the *Informix® Guide to SQL: Reference*.)

In multiple-assignment operations, the number of variables to the left of the equal (=) sign must match the number of values returned by the functions, expressions, and queries listed on the right of the equal (=) sign. The following example shows several LET statements that assign values to SPL variables:

```

LET a = c + d ;
LET a,b = c,d ;
LET expire_dt = end_dt + 7 UNITS DAY;
LET name = 'Brunhilda';
LET sname = DBSERVERNAME;
LET this_day = TODAY;

```

497. See [Arguments on page 1433](#)

498. See [Expression on page 1193](#)

499. See [SELECT statement on page 768](#)

You cannot use multiple values to the right of the equal (=) sign to operate on other values. For example, the following statement is not valid:

```
LET a,b = (c,d) + (10,15); -- INVALID EXPRESSION
```

### Related reference

[EXECUTE PROCEDURE statement on page 557](#)

## Using a SELECT Statement in a LET Statement

The examples in this section use a SELECT statement in a LET statement. You can use a SELECT statement to assign values to one or more variables on the left side of the equals (=) operator, as the following example shows:

```
LET a,b = (SELECT c1,c2 FROM t WHERE id = 1);
LET a,b,c = (SELECT c1,c2 FROM t WHERE id = 1), 15;
```

You cannot use a SELECT statement to make multiple values operate on other values. The following example is invalid:

```
LET a,b = (SELECT c1,c2 FROM t) + (10,15); -- INVALID CODE
```

Because a LET statement is equivalent to a SELECT ... INTO statement, the two statements in the following example have the same results: `a=c` and `b=d`:

```
CREATE PROCEDURE proof()
  DEFINE a, b, c, d INT;
  LET a,b = (SELECT c1,c2 FROM t WHERE id = 1);
  SELECT c1, c2 INTO c, d FROM t WHERE id = 1
END PROCEDURE
```

If the SELECT statement returns more than one row, you must enclose the SELECT statement in a FOREACH loop.

For a description of SELECT syntax and usage, see [SELECT statement on page 768](#).

## Calling a Function in a LET Statement

You can call a user-defined function in a LET statement and assign the returned values to an SPL variable that receives the values that the function returns.

An SPL function can return multiple values (that is, values from multiple columns in the same row) into a list of variable names. In other words, the function can have multiple values in its RETURN statement and the LET statement can have multiple variables to receive the returned values.

When you call the function, you must specify all the necessary arguments to the function unless the arguments of the function have default values. If you specify the name of one of the parameters in the called function with syntax such as **name = 'smith'**, you must name all of the parameters.

An SPL function that selects and returns more than one row must be enclosed in a FOREACH loop.

The following two examples show valid LET statements:

```
LET a, b, c = func1(name = 'grok', age = 17);
LET a, b, c = 7, func2('orange', 'green');
```

The following LET statement is not valid because it tries to add the output of two functions and then assign the sum to two variables, **a** and **b**.

```
LET a, b = func1() + func2(); -- INVALID CODE
```

You can easily split this LET statement into two valid LET statements:

```
LET a = (func1() + func2());
LET b = a; -- VALID CODE
```

A function called in a LET statement can have an argument of COLLECTION, SET, MULTISSET, or LIST. You can assign the value that the function returns to a variable, for example:

```
LET d = function1(collection1);
LET a = function2(set1);
```

In the first statement, the SPL function **function1** accepts **collection1** (that is, any collection data type) as an argument and returns its value to the variable **d**. In the second statement, the SPL function **function2** accepts **set1** as an argument and returns a value to the variable **a**.

## LOOP

Use the LOOP statement to define a loop with an indeterminate number of iterations.

### Syntax

```
<<label >>
```

#### WHILE

```
Condition500
```

```
FORloop_var
```

```
IN(
```

```
Range
```

```
expression
```

```
)
```

```
= Range
```

#### LOOP

```
Statement Block501
```

#### END LOOP

```
label502
```

```
;
```

```
Range
```

```
left_expressionTOright_expression
```

```
STEPincrement_expr
```

500. See [Condition on page 1144](#)

501. See [Statement Block on page 1522](#)

502. Valid only if <<label>> precedes the first keyword

| Element                 | Description  | Restrictions  | Syntax                                  |
|-------------------------|--|---|---|
| <i>expression</i>       | Value to compare with <i>loop_var</i>                              | Must match <i>loop_var</i> data type                          | <a href="#">Expression on page 1193</a> |
| <i>increment_expr</i>   | Positive or negative value by which <i>loop_var</i> is incremented | Must return an integer. Cannot return 0.                      | <a href="#">Expression on page 1193</a> |
| <i>label</i>            | Name of the loop label for this loop                               | Must be unique among labels in this SPL routine               | <a href="#">Identifier on page 1456</a> |
| <i>left_expression</i>  | Starting expression of a range                                     | Value must match SMALLINT or INT data type of <i>loop_var</i> | <a href="#">Expression on page 1193</a> |
| <i>loop_var</i>         | Variable that determines how many times the loop executes          | Must be defined and in scope within this statement block      | <a href="#">Identifier on page 1456</a> |
| <i>right_expression</i> | Ending expression in the range                                     | Same as for <i>left_expression</i>                            | <a href="#">Expression on page 1193</a> |

## Usage

The LOOP statement is an iterative statement that resembles the FOR and WHILE statements. Like FOR and WHILE, the LOOP statement can have an optional loop label, It can include the CONTINUE statement to specify another iteration, and the EXIT statement to terminate execution of the loop.

Besides resembling FOR and WHILE in its functionality, the LOOP statement can use the syntax of FOR or WHILE that precedes the statement block. Sections that follow describe several forms of the LOOP statement, including these:

- Simple LOOP statements that iterate a statement loop indefinitely
- FOR LOOP statements, that use FOR statement syntax specify a finite number of iterations
- WHILE LOOP statements, that iterate while a specified condition is true
- Labeled versions of each of these LOOP statements, which can terminate deeply nested loops.

## Simple LOOP Statements

The following program fragment illustrates a simple form of the LOOP statement.

```

LOOP
LET i = i + 1;
  IF i = 5 THEN EXIT;
  ELSE
  CONTINUE;
  END IF
END LOOP;

```

In this example the IF statement limits the number of iterations. Here the CONTINUE and EXIT statements omit the optional LOOP keyword, but the END LOOP statement is required at the end of the statement loop. A similar FOR or WHILE keyword would have required the FOR or WHILE keywords, respectively, in the CONTINUE and EXIT statements.

The next example uses a conditional EXIT statement to terminate the loop:

```

LOOP
LET i = i + 1;
  EXIT WHEN i = 4;
END LOOP;

```

No keyword identifying the type of loop statement is required after the EXIT statement, as would be the case for an EXIT statement in a FOR, WHILE, or FOREACH statement. When the `i = 4` condition becomes true, program control passes from the LOOP statement to whatever statement follows the END LOOP keywords.

## FOR LOOP Statements

The FOR LOOP statement uses FOR statement syntax to specify a variable and a range of values that the variable can take. The loop iterates until the specified limit to these values is reached, or until control is transferred outside the loop, as by the unconditional EXIT statement in the following example:

```

FOR i IN (1 TO 5) LOOP
  IF i = 5 THEN EXIT;
  ELSE
    CONTINUE;
  END IF;
END LOOP;

```

In the FOR LOOP statement, the FOR keyword can follow the EXIT or CONTINUE keyword, but the FOR keyword is not required, as it is in an ordinary FOR statement.

The following example replaces the IF statement with a functionally equivalent conditional EXIT statement:

```

FOR i IN (1 TO 5) LOOP
  EXIT WHEN i = 5;
END LOOP;

```

## WHILE LOOP Statements

To create a WHILE LOOP statement, loop, you can immediately follow a WHILE *condition* specification with a LOOP statement. The resulting loop terminates after the *condition* becomes false, or when some other statement transfers program control from the loop. In the following WHILE LOOP statement, the condition specifies that the loop terminates after the loop variable `i` has been incremented to the value of 6:

```

WHILE (i < 6) LOOP
  LET i = i + 1;
  IF i = 5 THEN EXIT;
  ELSE
    CONTINUE;
  END IF;
END LOOP;

```

As in the FOR LOOP statement, the EXIT and CONTINUE keywords do not need to specify the type of loop statement, but the example would not be affected if EXIT WHILE and CONTINUE WHILE replaced the EXIT and CONTINUE keywords. The END LOOP keywords are required, however, because Informix® treats the WHILE LOOP (and FOR LOOP) statements as LOOP statements, despite their initial FOR and WHILE specifications.

## Labeled LOOP Statements

### About this task

All forms of the LOOP statement, including the FOR LOOP, WHILE LOOP, and simple LOOP statements can have statement labels. You can create a labeled LOOP statement in the following steps:

1. Write a valid LOOP, FOR LOOP, or WHILE LOOP statement.
2. Create a statement label by enclosing an SQL identifier (that is not already the name of a label in the same SPL routine) between angle brackets (`<<loop_label>>`) immediately before the first line of the LOOP, FOR LOOP, or WHILE LOOP statement.
3. Enter the same SQL identifier, but without angle bracket delimiters, immediately after the END LOOP keywords that terminate the statement, which is now a labeled loop statement.

One advantage of labeled LOOP statements is that they can be referenced in EXIT statements. When the EXIT *label* statement executes, program control passes from the EXIT statement to the statement that follows the specified loop label. In the following example, a labeled WHILE LOOP loop, whose loop label identifier is **endo**, is part of the statement block of a labeled LOOP statement whose loop label identifier is **voort**. If the conditional EXIT statement `EXIT endo WHEN x = 7;` detects that its condition is true, program control passes to the `LET x = x + 1` statement that follows the `END LOOP endo` statement. If the conditional EXIT statement `EXIT voort WHEN x > 9;` detects that its condition is true, program control passes to the `LET x = x + 1` statement that follows the `END LOOP voort` statement, and the value of x is not incremented by the LET statement,

```
<<voort>>
LOOP
  LET x = x+1;
  <<endo>>
  WHILE ( i < 10 ) LOOP
    LET x = x+1;
    EXIT endo WHEN x = 7;
    EXIT voort WHEN x > 9;
    END LOOP endo;
    LET x = x+1;
  END LOOP voort;
```

uses FOR statement syntax to specify a variable and a range of values that the variable can take. The loop iterates until the specified limit to these values is reached, or until control is transferred outside the loop, as by the unconditional EXIT statement in the following example:

```
FOR i IN (1 TO 5) LOOP
  IF i = 5 THEN EXIT;
  ELSE
  CONTINUE;
END LOOP;
```

In the FOR LOOP statement, the FOR keyword can follow the EXIT or CONTINUE keyword, but the FOR keyword is not required, as it is in an ordinary FOR statement.

The following example replaces the IF statement with a functionally equivalent conditional EXIT statement:

```
FOR i IN (1 TO 5) LOOP
  EXIT WHEN i = 5;
END LOOP;
```

**Example****Related Statements**

<< Label >> statement on page 1081, FOR on page 1103, WHILE on page 1136

**ON EXCEPTION**

Use the ON EXCEPTION statement to specify actions to be taken for any error, or for a list of one or more specified errors, during execution of a statement block.

**Syntax**

```

ON EXCEPTION
IN(
, error_number
)
SETSQL_error_var
,ISAM_error_var
,error_data_var
Statement Block503
END EXCEPTION
WITH RESUME
;

```

| Element               | Description   | Restrictions   | Syntax                                      |
|-----------------------|---|--|---|
| <i>error_data_var</i> | SPL variable to receive a string returned by an SQL error or by a user-defined exception  | Must be a character type to receive the error information. Must be valid in current statement block. | <a href="#">Identifier on page 1456</a>     |
| <i>error_number</i>   | SQL error number or a number defined by a RAISE EXCEPTION statement that is to be trapped | Must be of integer type. Must be valid in current statement block.                                   | <a href="#">Literal Number on page 1419</a> |
| <i>ISAM_error_var</i> | SPL variable that receives the ISAM error number of the exception raised                  | Same as for <i>error_number</i>  | <a href="#">Identifier on page 1456</a>     |
| <i>SQL_error_var</i>  | SPL variable that receives the SQL error number of the exception raised                   | Same as for <i>ISAM_error_var</i>  | <a href="#">Identifier on page 1456</a>     |

**Usage**

The ON EXCEPTION statement, together with the RAISE EXCEPTION statement, provides an error-trapping and error-recovery mechanism for SPL routines. ON EXCEPTION can specify the errors that you want to trap as the SPL routine executes, and

503. See [Statement Block on page 1522](#)

specifies the action to take if the error occurs within the statement block. The ON EXCEPTION statement can list one or more specific error numbers in the IN clause, or it can trap all errors (or any error) if the IN clause is omitted.

A statement block can include more than one ON EXCEPTION statement. The exceptions that are trapped can be either system-defined or user-defined.

The scope of the ON EXCEPTION statement is the statement block that contains it, and any statement blocks that are nested within that statement block, unless one of the nested statement blocks provides an ON EXCEPTION statement that overrides the outer one.

When an exception is trapped, the error status is cleared.

If you specify a variable to receive an ISAM error, but no accompanying ISAM error exists, a zero (0) is assigned to the variable. If you specify a variable to receive the error text, but none exists, the variable stores an empty string.

### No ON EXCEPTION Support in Triggered Actions

The ON EXCEPTION statement has no effect when it is issued from an SPL routine in the following calling contexts:

- in a trigger routine,
- in the Action clause or the Correlated Action clause of a trigger on a table,
- in the Action clause of an INSTEAD OF trigger on a view.

When a UDR includes ON EXCEPTION in any of these contexts, the database server ignores the ON EXCEPTION statement.

## Placement of the ON EXCEPTION statement

The ON EXCEPTION statement is a declarative statement, not an executable statement. For this reason, ON EXCEPTION must follow immediately after any DEFINE statements, and must precede any executable statement within the same SPL statement block.

Because the body of the SPL routine is a statement block, the ON EXCEPTION statement often appears at the top of the routine, and applies to all of the code in the routine.

The following example positions an ON EXCEPTION statement so that a FOREACH statement can continue processing rows after an error occurs. Procedure X() reads customer numbers from table A and inserts them into table B. Because the INSERT statement is in scope of the ON EXCEPTION statement, any error during an INSERT operation causes control of execution to move to the next row of the FOREACH cursor, without terminating the FOREACH loop.

```
CREATE PROCEDURE X()

  DEFINE v_cust_num CHAR(20);

  FOREACH cs_insert FOR SELECT cust_num INTO v_cust_num FROM A
  BEGIN
    ON EXCEPTION
    END EXCEPTION WITH RESUME;
    INSERT INTO B(cust_num) VALUES(v_cust_num);
  END
END FOREACH
```

```
END PROCEDURE
```

In the next example, function `add_salesperson()` inserts a set of values into a table. If the table does not exist, it is created, and the values are inserted. The function also returns the total number of rows in the table after the insert occurs:

```
CREATE FUNCTION add_salesperson(last CHAR(15), first CHAR(15))
RETURNING INT;
DEFINE x INT;
ON EXCEPTION IN (-206) -- If no table was found, create one
  CREATE TABLE emp_list
    (lname CHAR(15), fname CHAR(15), tele CHAR(12));
  INSERT INTO emp_list VALUES -- and insert values
    (last, first, '800-555-1234');
END EXCEPTION WITH RESUME;
INSERT INTO emp_list VALUES (last, first, '800-555-1234');
SELECT count(*) INTO x FROM emp_list;
RETURN x;
END FUNCTION;
```

When an error occurs, the database server searches for the last `ON EXCEPTION` statement that traps the error code. If the database server finds no pertinent `ON EXCEPTION` statement, the error code is passed back to the calling context (the SPL routine, application, or interactive user), and execution terminates.

In the previous example, the minus sign (-) is required in the `IN` clause that specifies error -206; most error codes are negative integers.

The next example uses two `ON EXCEPTION` statements with the same error number so that error code 691 can be trapped in two levels of nesting. All of the `DELETE` statements except the one that is marked { 6 } are within the scope of the first `ON EXCEPTION` statement. The `DELETE` statements that are marked { 1 } and { 2 } are within the scope of the inner `ON EXCEPTION` statement:

```
CREATE PROCEDURE delete_cust (cnum INT)
ON EXCEPTION IN (-691) -- children exist
BEGIN -- Begin-end so no other DELETes get caught in here.
  ON EXCEPTION IN (-691)
    DELETE FROM another_child WHERE num = cnum; { 1 }
    DELETE FROM orders WHERE customer_num = cnum; { 2 }
  END EXCEPTION -- for error -691
  DELETE FROM orders WHERE customer_num = cnum; { 3 }
END
DELETE FROM cust_calls WHERE customer_num = cnum; { 4 }
DELETE FROM customer WHERE customer_num = cnum; { 5 }
END EXCEPTION
DELETE FROM customer WHERE customer_num = cnum; { 6 }
END PROCEDURE
```

## Using the IN Clause to Trap Specific Exceptions

An error is trapped if the SQL error code or the ISAM error code matches an exception code in the list of error numbers. The search through the list of errors begins from the left and stops with the first match. You can use a combination of an `ON EXCEPTION` statement without an `IN` clause and one or more `ON EXCEPTION` statements with an `IN` clause. When an error occurs, the database server searches for the last declaration of the `ON EXCEPTION` statement that traps the particular error code.

```

CREATE PROCEDURE ex_test()
  DEFINE error_num INT;
  ...
  ON EXCEPTION SET error_num
  -- action C
  END EXCEPTION
  ON EXCEPTION IN (-300)
  -- action B
  END EXCEPTION
  ON EXCEPTION IN (-210, -211, -212) SET error_num
  -- action A
  END EXCEPTION

```

A summary of the sequence of statements in the previous example would be:

1. Test for an error.
2. If error `-210`, `-211`, or `-212` occurs, take action `A`.
3. If error `-300` occurs, take action `B`.
4. If any other error occurs, take action `C`.

## Receiving Error Information in the SET Clause

If you use the SET clause, when an exception occurs, the SQL error code and (optionally) the ISAM error code are inserted into the variables that are specified in the SET clause. If you provide an *error\_data\_var*, any error text that the database server returns is put into the *error\_data\_var*. Error text includes information such as the offending table or column name.

## Forcing Continuation of the Routine

The first example in [Placement of the ON EXCEPTION statement on page 1125](#) includes the WITH RESUME keyword to specify that if the ON EXCEPTION statement traps an error, execution of the FOREACH loop resumes on the next row of the `cs_insert` cursor, the row immediately following the row on which the error was raised. If an error is issued on the last row of the active set, the procedure exits. After procedure `X` completes execution, table `B` contains a copy of every customer number in table `A` on which no error was issued during the INSERT operation.

The second example in [Placement of the ON EXCEPTION statement on page 1125](#) uses the WITH RESUME keyword to indicate that after the statement block in the ON EXCEPTION statement executes, execution is to continue at the `SELECT COUNT(*) FROM emp_list` statement, which is the line following the line that raised the error. For this function, the result is that the count of salespeople names occurs even if the error occurred.

## Continuing Execution After an Exception Occurs

If you omit the WITH RESUME keywords, the next statement that executes after an exception occurs depends on the placement of the ON EXCEPTION statement, as the following scenarios describe:

- If the ON EXCEPTION statement is inside a statement block with a BEGIN and an END keyword, execution resumes with the first statement (if any) after that BEGIN ... END block. That is, it resumes after the scope of the ON EXCEPTION statement.
- If the ON EXCEPTION statement is inside a loop (FOR, WHILE, FOREACH), the rest of the loop is skipped, and execution resumes with the next iteration of the loop.
- If no statement or block, but only the SPL routine, contains the ON EXCEPTION statement, the routine executes a RETURN statement with no arguments, returning a successful status and no values.

To prevent an infinite loop, if an error occurs during execution of the statement block, then the search for another ON EXCEPTION statement to trap the error does not include the current ON EXCEPTION statement.

## Related Statements

[RAISE EXCEPTION on page 1128](#)

## RAISE EXCEPTION

Use the RAISE EXCEPTION statement to simulate the generation of an error.

### Syntax

```
RAISE EXCEPTION SQL_error_var
,ISAM_error
,error_text
;
```

| Element           | Description  | Restrictions   | Syntax   |
|-------------------|--|--|--|
| <i>error_text</i> | SPL variable or expression that contains error message text for error -746               | Must be a character data type and be valid in the statement block                              | <a href="#">Identifier on page 1456</a> ;<br><a href="#">Expression on page 1193</a> |
| <i>ISAM_error</i> | SPL variable or other expression that represents an ISAM error number. The default is 0. | Must return a value in SMALLINT range. You can specify a unary minus sign before error number. | <a href="#">Expression on page 1193</a>  |
| <i>SQL_error</i>  | SPL variable or other expression that represents an SQL error number                     | Same as for <i>ISAM_error</i>  | <a href="#">Expression on page 1193</a>  |

### Usage

Use the RAISE EXCEPTION statement to simulate an error or to generate an error with a custom message. An ON EXCEPTION statement can trap the generated error.

If you omit *ISAM\_error*, the database server sets the ISAM error code to zero (0) when the exception is raised. If you want to specify *error\_text* but not specify a value for *ISAM\_error*, specify zero (0) as the value of *ISAM\_error*.

The RAISE EXCEPTION statement can raise either system-generated exceptions or user-generated exceptions. For example, the following statement raises the error number -208:

```
RAISE EXCEPTION -208, 0;
```

Here the minus ( - ) symbol is required after the EXCEPTION keyword for error -208; most error codes are negative integers.

## Special Error Number -746

The special error number -746 allows you to produce a customized message. For example, the following statement raises the error number -746 and returns the quoted text:

```
RAISE EXCEPTION -746, 0, 'You broke the rules';
```

In the following example, a negative value for **alpha** raises exception -746 and provides a specific message that describes the problem. The code should contain an ON EXCEPTION statement that traps for an exception of -746.

```
FOREACH SELECT c1 INTO alpha FROM sometable
IF alpha < 0 THEN
RAISE EXCEPTION -746, 0, 'a < 0 found' -- emergency exit
END IF
END FOREACH
```

When the SPL routine executes and the IF condition is met, the database server returns the following error:

```
-746: a < 0 found.
```

For more information about the scope and compatibility of exceptions, see [ON EXCEPTION on page 1124](#).

## Related Statements

[ON EXCEPTION on page 1124](#)

## RETURN

Use the RETURN statement to specify what values (if any) the SPL function returns to the calling context.

### Syntax

#### RETURN

, Expression<sup>504</sup>

#### WITH RESUME

;

### Usage

In Informix®, for backward compatibility, you can use the RETURN statement inside a CREATE PROCEDURE statement to create an SPL function. By only using RETURN in CREATE FUNCTION statements, however, you can maintain the convention of using CREATE FUNCTION to define routines that return a value, and CREATE PROCEDURE for other routines.

504. See [Expression on page 1193](#)

All RETURN statements in the SPL function must be consistent with the RETURNING clause of the CREATE FUNCTION (or CREATE PROCEDURE) statement that defines the function. Any RETURN list of expressions must match in cardinality (and be of data types compatible with) the ordered list of data types in the RETURNING clause of the function definition.

Alternatively, however, the RETURN statement can specify no expressions, even if the RETURNING clause lists one or more data types. In this case, a RETURN statement that specifies no expression is equivalent to returning the expected number of NULL values to the calling context. A RETURN statement without any expressions exits only if the SPL function is declared as not returning any values. Otherwise it returns NULL values.

The following SPL function has two valid RETURN statements:

```
CREATE FUNCTION two_returns (stockno INT) RETURNING CHAR (15);
  DEFINE des CHAR(15);
  ON EXCEPTION (-272)      -- if user does not have select privilege
    RETURN;                -- return no values.
  END EXCEPTION;
  SELECT DISTINCT descript INTO des FROM stock
    WHERE stock_num = stockno;
  RETURN des;
END FUNCTION;
```

A program that calls the function in the previous example should test whether no values are returned and act accordingly.

## WITH RESUME Keyword

If you use the WITH RESUME keywords, then after the RETURN statement completes execution, the next invocation of the SPL function (upon the next FETCH or FOREACH statement) starts from the statement that follows the RETURN statement. Any function that executes a RETURN WITH RESUME statement must be invoked within a FOREACH loop, or else in the FROM clause of a SELECT statement. If an SPL routine executes a RETURN WITH RESUME statement, a FETCH statement in the Informix® ESQL/C application can call the SPL routine.

The following example shows a cursor function that another UDR can call. After the RETURN WITH RESUME statement returns each value to the calling UDR or program, the next line of **series** executes the next time **series** is called. If the variable **backwards** equals zero (0), no value is returned to the calling UDR or program, and execution of **series** stops:

```
CREATE FUNCTION series (limit INT, backwards INT) RETURNING INT;
  DEFINE i INT;
  FOR i IN (1 TO limit)
    RETURN i WITH RESUME;
  END FOR;
  IF backwards = 0 THEN
    RETURN;
  END IF;
  FOR i IN (limit TO 1 STEP -1)
    RETURN i WITH RESUME;
  END FOR;
END FUNCTION; -- series
```

## Returning Values from Another Database

If an SPL function uses the Return clause to return values from another database of the local Informix® instance, the following data types are supported as the returned data type:

- Built-in data types that are not opaque
- Most of the *built-in opaque data types*, as listed in [Data Types in Cross-Database Transactions on page 779](#)
- DISTINCT of the built-in types that are referenced in the two lines above
- DISTINCT of any DISTINCT data type in this list
- Any opaque user-defined type (UDT) that is cast explicitly to one of the built-in data types in this list.

The definitions of the UDF and of the type hierarchies, casts, DISTINCT types, and UDTs must be exactly the same in each of the participating databases. The same data-type restrictions apply to a value that an external function returns from another database of the local Informix® instance. For more information about data types that are supported in distributed operations across two or more databases of the same database server, see [Data Types in Cross-Database Transactions on page 779](#).

UDRs can return only the following data types from tables in databases of other database servers:

- Any non-opaque built-in data type
- BOOLEAN
- LVARCHAR
- DISTINCT of non-opaque built-in types
- DISTINCT of BOOLEAN
- DISTINCT of LVARCHAR
- DISTINCT of any DISTINCT type that appears in this list.

UDRs can return these DISTINCT types from databases of other Informix® instances only if the DISTINCT types are cast explicitly to built-in types. The definitions of the DISTINCT data types, their type hierarchies, and their casts must be exactly the same in all databases that participate in the distributed operations. For queries or other DML operations in cross-server UDRs that use the data types in the preceding list as parameters or as returned data types, the UDR must be defined in each participating database, and the participating Informix® instances must support the data type as a returned value in cross-server operations.

For additional information about the data types that Informix® can access in distributed operations, see [Data Types in Distributed Queries on page 779](#).

## External Functions and Iterator Functions

In an SPL program, you can use a C or Java™ language external function as an expression in a RETURN statement, provided that the external function is not an iterator function. An *iterator function* is an external function that returns one or more rows of data (and therefore requires a cursor to execute).

SPL iterator functions must include the RETURN WITH RESUME statement. For information about using an iterator function with a virtual table interface in the FROM clause of a query, see [Iterator Functions on page 801](#).

## SYSTEM

Use the SYSTEM statement to issue an operating-system command from within an SPL routine.

### Syntax

#### SYSTEM

```
expression SPL_var
```

```
;
```

| Element           | Description   | Restrictions  | Syntax                                   |
|-------------------|---|---|--|
| <i>expression</i> | Evaluates to a user-executable operating-system command | You cannot specify that the command run in the background | Operating-system dependent               |
| <i>SPL_var</i>    | SPL variable containing a command                       | Must be of a character data type                          | <a href="#">Identifier on page 1456;</a> |

### Usage

If the specified *expression* is not a character expression, it is converted to a character expression and passed to the operating system for execution.

The command that SYSTEM specifies cannot run in the background. The database server waits for the operating system to complete execution of the command before it continues to the next statement in the SPL routine. The SPL routine cannot use any returned values from the command.

If the operating-system command fails (that is, returns a nonzero status for the command), an exception is raised that contains the returned operating-system status as the ISAM error code and an appropriate SQL error code.

A rollback does not terminate a system call, so a suspended transaction can wait indefinitely for the call to return. For instructions on recovery from a deadlock during a long transaction rollback, see the *Informix® Administrator's Guide*.

The dynamic log feature of Informix® automatically adds log files until the long transaction completes or rolls back successfully.

In DBA- and owner-privileged SPL routines that contain SYSTEM statements, the command runs with the access privileges of the user who executes the routine.

## Executing the SYSTEM statement on UNIX™

In SPL procedures for UNIX™ platforms, a specification that evaluates to a valid UNIX™ operating system command must immediately follow the SYSTEM keyword.

Both of the program fragments that follow use the SYSTEM statement of SPL to send a message to the system administrator.

- In the first example, the **sensitive\_update** routine defines an SPL variable called **mailcall** to store a character string that specifies the name of the **mail** utility, and the user ID of the message recipient, and the message text.
- In the second example, the **sensitive\_update2** routine similarly invokes the **mail** utility with a **SYSTEM** statement. The expression constructs a valid command line by concatenating three quoted strings and the SPL variables **user1** and **user2** to send to the system administrator a file called **violations\_file**.

## Sending email using the SYSTEM statement

The **SYSTEM** statement in the following example of an SPL routine causes the UNIX™ operating system to send a mail message to the system administrator whose user ID is **headhoncho**:

```
CREATE PROCEDURE sensitive_update()
...
LET mailcall = 'mail headhoncho < alert';
-- code to execute if user tries to execute a specified
-- command, then sends email to system administrator
SYSTEM mailcall;
...
END PROCEDURE; -- sensitive_update
```

You can use a double-pipe symbol ( `||` ) to concatenate expressions within a **SYSTEM** statement, as the following example shows:

```
CREATE PROCEDURE sensitive_update2()
DEFINE user1 char(15);
DEFINE user2 char(15);
LET user1 = 'joe';
LET user2 = 'mary';
...
-- code to execute if user tries to execute a specified
-- command, then sends email to system administrator
SYSTEM 'mail -s violation' || user1 || ' ' || user2
      || '< violation_file';
...
END PROCEDURE; --sensitive_update2
```

In both examples above, blank spaces separate elements of the command line, so the expression that follows the **SYSTEM** keyword evaluates to a character string that conforms to the syntax requirements of the operating system mail utility.

## Executing the SYSTEM statement on Windows™

On Windows™ systems, any **SYSTEM** statements in an SPL routine are executed only if the current user who is executing the SPL routine has logged on with a password.

The database server must have the password and login name of the user in order to execute a command on behalf of that user.

The first **SYSTEM** statement in the following example of an SPL routine causes Windows™ to send an error message to a temporary file and to put the message in a system log that is sorted alphabetically. The second **SYSTEM** statement causes the operating system to delete the temporary file:

```
CREATE PROCEDURE test_proc()
...
```

```

SYSTEM 'type errormess101 > %tmp%tmpfile.txt |
      sort >> %SystemRoot%systemlog.txt';
SYSTEM 'del %tmp%tmpfile.txt';
...
END PROCEDURE; --test_proc

```

The expressions that follow the SYSTEM statements in this example contain variables **%tmp%** and **%SystemRoot%** that are defined by Windows™.

## Setting Environment Variables in SYSTEM Commands

### About this task

When the operating-system command that SYSTEM specifies is executed, no guarantee exists that any environment variables that the user application sets are passed to the operating system. If you set an environment variable in a SYSTEM command, the setting is only valid during that SYSTEM command.

To avoid this potential problem, the following method is recommended to ensure that any environment variables that the user application requires are carried forward to the operating system.

To Change Environment Settings for an Operating System Command

1. Create a shell script (on UNIX™ systems) or a batch file (on Windows™ platforms) that sets up the desired environment and then executes the operating system command.
2. Use the SYSTEM command to execute the shell script or batch file.

### Results

This solution has an additional advantage: if you subsequently need to change the environment, you can modify the shell script or the batch file without needing to recompile the SPL routine.

For information about operating system commands that set environment variables, see the *Informix® Guide to SQL: Reference*.

## TRACE

Use the TRACE statement to control the generation of debugging output.

### Syntax

#### TRACE

#### ON OFF PROCEDURE

Expression<sup>505</sup>

;

505. See [Expression on page 1193](#)

## Usage

The TRACE statement generates output that is sent to the file that the SET DEBUG FILE TO statement specifies. Tracing writes to the debug file the current values of the following program objects:

- SPL variables
- Routine arguments
- Return values
- SQL error codes
- ISAM error codes

The output of each executed TRACE statement appears on a separate line.

If you use the TRACE statement before you specify a DEBUG file to contain the output, an error is generated.

Any routine that the SPL routine calls inherits the trace state. That is, a called routine (on the same database server) assumes the same trace state (ON, OFF, or PROCEDURE) as the calling routine. The called routine can set its own trace state, but that state is not passed back to the calling routine.

A routine that is executed on a remote database server does not inherit the trace state.

---

### Related reference

[SET DEBUG FILE statement on page 886](#)

## TRACE ON

If you specify the keyword ON, all statements are traced. The values of variables (in expressions or otherwise) are printed before they are used. To turn tracing ON implies tracing both routine calls and statements in the body of the routine.

## TRACE OFF

If you specify the keyword OFF, all tracing is turned off.

## TRACE PROCEDURE

If you specify the keyword PROCEDURE, only the routine calls and return values, but not the body of the routine, are traced.

The TRACE statement supports no ROUTINE or FUNCTION keywords. Use the TRACE PROCEDURE keywords when the SPL routine that you trace is a function.

## Displaying Expressions

You can use the TRACE statement with a quoted string or an expression to display values or comments in the output file. If the expression is not a literal expression, the expression is evaluated before it is written to the output file.

You can use the TRACE statement with an expression even if you used a TRACE OFF statement earlier in a routine. You must first, however, use the SET DEBUG statement to establish a trace output file.

The next example uses a TRACE statement with an expression after using a TRACE OFF statement. The example uses UNIX™ file naming conventions:

```
CREATE PROCEDURE tracing ()
  DEFINE i INT;
BEGIN
  ON EXCEPTION IN (1)
  END EXCEPTION; -- do nothing
  SET DEBUG FILE TO '/tmp/foo.trace';
  TRACE OFF;
  TRACE 'Forloop starts';
  FOR i IN (1 TO 1000)
    BEGIN
      TRACE 'FOREACH starts';
      FOREACH SELECT...INTO a FROM t
        IF <some condition> THEN
          RAISE EXCEPTION 1 -- emergency exit
        END IF
      END FOREACH -- return some value
    END
  END FOR -- do something
END;
END PROCEDURE
```

## Example Showing Different Forms of TRACE

The following example shows several different forms of the TRACE statement. The example uses Windows™ file naming conventions:

```
CREATE PROCEDURE testproc()
  DEFINE i INT;
  SET DEBUG FILE TO 'C:\tmp\test.trace';
  TRACE OFF;
  TRACE 'Entering foo';
  TRACE PROCEDURE;
  LET i = test2();

  TRACE ON;
  LET i = i + 1;

  TRACE OFF;
  TRACE 'i+1 = ' || i+1;
  TRACE 'Exiting testproc';

  SET DEBUG FILE TO 'C:\tmp\test2.trace';

END PROCEDURE
```

## Looking at the Traced Output

### About this task

To see the traced output, use a text editor or similar utility to display or read the contents of the file.

## WHILE

Use the WHILE statement to establish a loop with variable end conditions.

### Syntax

```
<<label >>
```

#### WHILE

Condition<sup>506</sup>

Statement Block<sup>507</sup>

#### END WHILE

label<sup>508</sup>

#### LOOP

Statement Block<sup>507</sup>

#### END LOOP

label<sup>508</sup>

```
;
```

| Element      | Description                          | Restrictions                                    | Syntax                                  |
|--------------|--------------------------------------|---|---|
| <i>label</i> | Name of the loop label for this loop | Must be unique among labels in this SPL routine | <a href="#">Identifier on page 1456</a> |

### Usage

The *condition* is evaluated before the *statement block* first runs and before each subsequent iteration. Iterations<sup>®</sup> continue as long as the *condition* remains true. The loop terminates when the *condition* evaluates to not true.

If any expression within the *condition* evaluates to NULL, the *condition* becomes not true unless you are explicitly testing for NULL with the IS NULL operator.

If an expression within the *condition* has an UNKNOWN value because it references uninitialized SPL variables, an immediate error results. In this case, the loop terminates, raising an exception.

### Example of WHILE Loops in an SPL Routine

The following example illustrates the use of WHILE loops in an SPL routine. In the SPL procedure, **simp\_while**, the first WHILE loop executes a DELETE statement. The second WHILE loop executes an INSERT statement and increments the value of an SPL variable.

```
CREATE PROCEDURE simp_while()
  DEFINE i INT;
  WHILE EXISTS (SELECT fname FROM customer
    WHERE customer_num > 400)
    DELETE FROM customer WHERE id_2 = 2;
  END WHILE;
```

506. See [Condition on page 1144](#)

507. See [Statement Block on page 1522](#)

508. Valid only if <<label>> precedes the first WHILE keyword

```

LET i = 1;
WHILE i < 10
  INSERT INTO tab_2 VALUES (i);
  LET i = i + 1;
END WHILE;
END PROCEDURE;

```

## Labeled WHILE Loops

To create a labeled WHILE loop, you can declare a loop label before the initial WHILE keyword, and repeat the label after the END WHILE keywords, as in the two WHILE loops of the following example:

```

CREATE PROCEDURE ex_cont_ex()
  DEFINE i,s,j, INT;
  <<while_jlab>>
  WHILE j < 20
    IF j > 10 THEN
      CONTINUE WHILE;
    END IF
    LET i,s = j,0;
    <<while_slab>>
    WHILE i > 0
      LET i = i -1;
      IF i = 5 THEN
        EXIT while_jlab;
      END IF
    END WHILE while_slab
  END WHILE while_jlab
END PROCEDURE;

```

Here the `EXIT while_jlab` statement has the same effect that the `EXIT` or `EXIT FOR` keywords would have, terminating both the outer WHILE loop and the routine. In this example, the statement that includes the `EXIT while_jlab` statement has the same effect that `EXIT while_jlab WHEN i = 5` would have.

You can also label a LOOP statement that begins with a loop `<<label>>` specification that immediately precedes the initial WHILE keyword and *condition*. In this type of loop, the CONTINUE LOOP, EXIT LOOP, and END LOOP keywords replace the CONTINUE WHILE, EXIT WHILE, and END WHILE keywords. Both the LOOP and WHILE keywords are optional after the CONTINUE and EXIT keywords, but the END LOOP keywords are required in SPL loop statements that include the LOOP keyword.

You can use similar syntax to create an unlabeled loop that omits the `<<label>>` declaration that immediately precedes the WHILE *condition* specification. In this case, you must also omit the undelimited loop label identifier that follows the END LOOP keywords. See the LOOP statement for a description and examples of these forms of labeled and unlabeled loop statements that enable you to combine WHILE statement syntax, with its condition-based number of loop iterations, with the "loop forever" syntax of the LOOP statement.

## Related Statements

[<< Label >> statement on page 1081](#), [CONTINUE on page 1088](#), [EXIT on page 1101](#), [LOOP on page 1120](#)

## Data types and expressions

These topics describe the data types and expressions that Informix® supports.

These fundamental syntax segments can appear in data definition language (DDL) and data manipulation language (DML) statements, and in other types of SQL statements. Some SPL statements can also specify data types or expressions. You can use these features of a relational or object-relational database in various contexts, such as to define the schema of a table, to specify the signature and arguments of a routine, or to represent or calculate specific data values.

---

### Related reference

[CREATE CAST statement on page 198](#)

## Scope of Segment Descriptions

The description of each segment includes the following information:

- A brief introduction that explains the effect of the segment
- A syntax diagram that shows how to enter the segment correctly
- A table that explains the terms in the syntax diagram for which you must substitute names, values, or other specific information
- Rules of usage, typically including examples that illustrate these rules

If a segment consists of multiple parts, the segment description provides similar information about each part. Some descriptions conclude with references to related information in this document and in other documents.

## Use of Segment Descriptions

The syntax diagram within each segment description is not a stand-alone diagram. Rather, it is a subdiagram of the syntax of the SQL statements (in [SQL statements on page 16](#)) or of SPL statements (in [SPL statements on page 1081](#)) that can include the segment.

SQL or SPL syntax descriptions can refer to segment descriptions in two ways:

- A *subdiagram reference* in a syntax diagram can list a segment name and the page in this document where the segment description begins.
- The **Syntax** column of the table that immediately follows a syntax diagram can list a segment name and the page where the segment description begins.

If the syntax diagram for a statement includes a reference to a segment, turn to that segment description to see the complete syntax for the segment.

For example, if you want to write a CREATE VIEW statement that includes a *database* and *database server* qualifiers of the view name, first look up the syntax diagram for the [CREATE VIEW statement on page 452](#). The table beneath that diagram refers to the Database Object Name segment for the syntax of *view*. Then use the Database Object Name segment

syntax to enter a valid CREATE VIEW statement that also specifies the *database* and *database server* name for the view. In the following example, the CREATE VIEW statement defines a view called **name\_only** in the **sales** database on the **boston** database server:

```
CREATE VIEW sales@boston:name_only AS
  SELECT customer_num, fname, lname FROM customer;
```

Besides the Data Types and Expressions syntax segments that this chapter documents, [Other syntax segments on page 1433](#) provides additional syntax segments that are referenced in the syntax diagrams of this document.

## Data type and expression segments

Data type and expression segments can appear in SQL statements.

Data type and expression segments can include the following items:

- Data Type
- DATETIME Field Qualifier
- INTERVAL Field Qualifier
- Expression
- Aggregate Expression
- AVG, COUNT, MAX, MIN, SUM, RANGE, STDEV, VARIANCE, *and* User-Defined Aggregates
- Arithmetic Expressions
- Binary ( +, -, \*, / ) Operators, Operator Functions, *and* Unary ( +, - ) Operators
- Cast Expressions
- CAST function *and* Cast ( :: ) Operator
- Collection Subquery
- Column Expressions
- Column Name, ROWID, *and* Substring ( [ ... ] ) Operator
- CONCAT Function *and* Concatenation ( || ) Operator
- Condition Segment *and* Conditional Expressions
- Comparison Condition: AND, OR, NOT, BETWEEN, IS NULL, LIKE, MATCHES, *and* Relational Operators
- Condition with Subquery: IN, EXISTS, ALL, ANY, *and* SOME Operators
- Boolean UDF
- CASE Expressions
- NVL Function
- DECODE Function
- Constant Expressions: CURRENT, SYSDATE, TODAY, DBSERVERNAME, SITENAME, UNITS, CURRENT\_USER, *and* USER
- Literal Value
- Literal Collection
- Literal DATETIME
- Literal INTERVAL
- Literal Number
- Literal Row
- Quoted String

- Constructor Expressions
- Collection Constructor
- ROW Constructor Function Expressions
- Algebraic Functions: ABS, MOD, POW, power ROOT, ROUND, SQRT, *and* TRUNC Functions
- CARDINALITY Function
- DBINFO Function
- Encryption and Decryption Functions: DECRYPT\_BINARY, DECRYPT\_CHAR, ENCRYPT\_AES, ENCRYPT\_TDES, *and* GETHINT Functions
- Exponential and Logarithmic Functions: EXP, LOGN, *and* LOG10 Functions
- HEX Function
- Hierarchical Query Operators and Functions: CONNECT\_BY\_ROOT, PRIOR, *and* SQL\_CONNECT\_BY\_PATH
- IFX\_ALLOW\_NEWLINE Function
- Length Functions: CHARACTER\_LENGTH, CHAR\_LENGTH, LENGTH, *and* OCTET\_LENGTH Functions
- Sequence Operators: CURRVAL, NEXTVAL
- Smart Large Object Functions: FILETOBLOB, FILETOCLOB, LOCOPY, *and* LOTOFILE Functions
- String-Manipulation Functions: LPAD, RPAD, TRIM, REPLACE, SUBSTR, SUBSTRING, INITCAP, LOWER, *and* UPPER Functions
- Time Functions: DATE, DAY, EXTEND, MDY, MONTH, TO\_CHAR, TO\_DATE, WEEKDAY, *and* YEAR Functions
- Trigger-Type Boolean Operators: DELETING, INSERTING, SELECTING, *and* UPDATING
- Trigonometric Functions: ACOS, ASIN, ATAN, ATAN2, COS, SIN, *and* TAN Functions
- User-Defined Functions
- Statement-Local Variable Expressions

You can also use host variables or SPL variables as expressions. For an alphabetic list of expressions with page references, see [List of Expressions on page 1195](#).

## Collection Subquery

You can use a Collection Subquery to create a MULTISET collection from the results of a subquery. This syntax is an extension to the ANSI/ISO standard for SQL.

### Syntax

Collection Subquery

<sup>509</sup>**MULTISET**

```
(
  subquery
SELECT ITEMsingleton_select
)
```

509. Informix® extension

| Element                            | Description                        | Restrictions   | Syntax                                       |
|------------------------------------|------------------------------------|--|--|
| <i>singleton</i><br><i>_select</i> | Subquery returning exactly one row | Subquery cannot repeat the SELECT keyword, nor include the ORDER BY clause | <a href="#">SELECT statement on page 768</a> |
| <i>subquery</i>                    | Embedded query                     | Cannot contain the ORDER BY clause   | <a href="#">SELECT statement on page 768</a> |

## Usage

The MULTISSET and SELECT ITEM keywords have the following significance:

- MULTISSET specifies a collection of elements that can contain duplicate values, but that has no specific order of elements.
- SELECT ITEM supports only one expression in the projection list. You cannot repeat the SELECT keyword in the singleton subquery.

You can use a collection subquery in the following contexts:

- The Projection clause and WHERE clause of the SELECT statement
- The VALUES clause of the INSERT statement
- The SET clause of the UPDATE statement
- Wherever you can use a collection expression (that is, any expression that evaluates to a single collection)
- As an argument passed to a user-defined routine

The following restrictions apply to a collection subquery:

- The Projection clause cannot contain duplicate column (field) names.
- It cannot contain aliases for table names. (But it can use aliases for column (field) names, as in some of the examples that follow. )
- It is read-only.
- It cannot be opened twice.
- It cannot contain NULL values.
- It cannot contain syntax that attempts to seek within the subquery.

A collection subquery returns a multiset of unnamed ROW data types. The fields of this ROW type are elements in the projection list of the subquery. Examples that follow access the tables and the ROW types that these statements define:

```
CREATE ROW TYPE rt1 (a INT);
CREATE ROW TYPE rt2 (x int, y rt1);
CREATE TABLE tab1 (col1 rt1, col2 rt2);
CREATE TABLE tab2 OF TYPE rt1;
CREATE TABLE tab3 (a ROW(x INT));
```

The following examples of collection subqueries return the MULTISSET collections that are listed to the right of the subquery.

| Collection Subquery                   | Resulting Collections             |
|---------------------------------------|-----------------------------------|
| MULTISET (SELECT * FROM tab1)...      | MULTISET(ROW(col1 rt1, col2 rt2)) |
| MULTISET (SELECT col2.y FROM tab1)... | MULTISET(ROW(y rt1))              |
| MULTISET (SELECT * FROM tab2)...      | MULTISET(ROW(a int))              |
| MULTISET(SELECT p FROM tab2 p)...     | MULTISET(ROW(p rt1))              |
| MULTISET (SELECT * FROM tab3)...      | MULTISET(ROW(a ROW(x int)))       |

The following is another collection subquery:

```
SELECT f(MULTISET(SELECT * FROM tab1 WHERE tab1.x = t.y))
FROM t WHERE t.name = 'john doe';
```

The following collection subquery includes the UNION operator:

```
SELECT f(MULTISET(SELECT id FROM tab1
UNION
SELECT id FROM tab2 WHERE tab2.id2 = tab3.id3)) FROM tab3;
```

## Table expressions in the FROM clause

Informix® supports ANSI/ISO standard syntax for table expressions in the FROM clause of SELECT queries and subqueries as a substitute for the Informix®-extension collection subquery syntax. The keywords TABLE and MULTISET are required in version 10.00 and in earlier releases. These extensions to the ANSI/ISO standard for SQL are supported but are no longer required for collection subqueries in the FROM clause of SELECT statements.

The following two queries return the same result set, but only the second query complies with the ANSI/ISO standard:

```
SELECT * FROM TABLE(MULTISET(SELECT col1 FROM tab1 WHERE col1 = 100))
AS vtab(c1),
(SELECT col1 FROM tab1 WHERE col1 = 10) AS vtab1(vc1) ORDER BY c1;

SELECT * FROM (SELECT col1 FROM tab1 WHERE col1 = 100) AS vtab(c1),
(SELECT col1 FROM tab1 WHERE col1 = 10) AS vtab1(vc1)
ORDER BY c1;
```

The same SELECT statement can combine instances of both the Informix®-extension and ANSI/ISO syntax for collection subqueries:

```
SELECT * FROM (select col1 FROM tab1 WHERE col1 = 100) AS vtab(c1),
TABLE(MULTISET(SELECT col1 FROM tab1 WHERE col1 = 10)) AS vtab1(vc1)
ORDER BY c1;
```

The collection subquery must be delimited by parentheses in both formats, but the outer set of parentheses ( ( ) ) that immediately follows the TABLE keyword and encloses the MULTISET collection subquery specification is an extension to the ANSI/ISO syntax. This ANSI/ISO syntax is valid only in the FROM clause of the SELECT statement. You cannot omit these keywords and parentheses from a collection subquery specification in any other context.

**Important:**

Collection subqueries in the FROM clause cannot include correlated table references, and cannot include the LATERAL keyword.

## Condition

Use a condition to test whether data meets certain qualifications. Use this segment wherever you see a reference to a condition in a syntax diagram.

### Syntax

Condition

Logical\_Operator

#### NOT

Comparison Conditions <sup>510</sup>

Condition with Subquery <sup>511</sup>

User-Defined Function <sup>512</sup>

| Element                      | Description             | Restrictions   | Syntax   |
|------------------------------|-------------------------|--|--|
| <i>Logical<br/>_Operator</i> | Combines two conditions | Valid options are OR (= <i>logical union</i> ) or AND (= <i>logical intersection</i> ) | <a href="#">Conditions with AND or OR on page 1162</a> |

### Usage

A *condition* is a search criterion, optionally connected by the logical operators AND or OR. Conditions can be classified into the following categories:

- Comparison conditions (also called filters or Boolean expressions)
- Conditions with a subquery
- User-defined functions (Informix® only)

A condition can contain an aggregate function only if it is used in the HAVING clause of a SELECT statement or in the HAVING clause of a subquery.

No aggregate function can appear in a condition in the WHERE clause of a DELETE, SELECT, or UPDATE statement unless both of the following are `TRUE`:

- Aggregate is on a correlated column originating from a parent query.
- The WHERE clause appears in a subquery within a HAVING clause.

In Informix®, user-defined functions are not valid as conditions in the following contexts:

510. See [Comparison Conditions \(Boolean Expressions\) on page 1145](#)

511. See [Condition with Subquery on page 1158](#)

512. See [User-Defined Functions on page 1362](#)

- In the HAVING clause of a SELECT statement
- In the definition of a check constraint

SPL routines are not valid as conditions in the following contexts:

- In the definition of a check constraint
- In the ON clause of a SELECT statement
- In the WHERE clause of a DELETE, SELECT, or UPDATE statement

External routines are not valid as conditions in the following contexts:

- In the definition of a check constraint
  - In the ON clause of a SELECT statement
  - In the WHERE clause of a DELETE, SELECT, or UPDATE statement
  - In the WHEN clause of CREATE TRIGGER
  - In the IF, CASE, or WHILE statements of SPL
- 

## Comparison Conditions (Boolean Expressions)

Comparison conditions are often called *Boolean expressions* because they return a `TRUE` or `FALSE` result.

Six kinds of Boolean operators can specify a comparison condition:

- Relational operators
- [NOT] BETWEEN AND operators
- [NOT] IN operators
- IS [NOT] NULL operators
- Trigger-type operators
- [NOT] LIKE or MATCHES operators

Their syntax is summarized in this diagram and explained in the sections that follow.

## Comparison Conditions

Expression<sup>514</sup>Relational Operator<sup>515</sup>Expression<sup>514</sup>Expression<sup>514</sup>**NOT****BETWEEN**Expression<sup>514</sup>**AND**Expression<sup>514</sup>

513

IN Condition<sup>516</sup>*column expression***IS****NOT****NULL**<sup>518</sup>Trigger-Type Operator<sup>519</sup>*string column***NOT****LIKE**<sup>513</sup>**MATCHES***string***ESCAPE 'char'***column*

| Element       | Description  | Restrictions   | Syntax                                       |
|---------------|--|--|--|
| <i>char</i>   | An ASCII character to be the escape character in the quoted string. Single ( ' ) and double ( " ) quotation marks are not valid as <i>char</i> . | See <a href="#">ESCAPE with LIKE on page 1157</a> and <a href="#">ESCAPE with MATCHES on page 1157</a> | <a href="#">Quoted String on page 1424</a>   |
| <i>column</i> | Name of a column (or a field of a ROW-type column) whose data value is compared to NULL, to <i>string</i> , or to another <i>column</i>          | Can be qualified by the identifier, synonym, or alias of a table or view                               | See <a href="#">Column Name on page 1147</a> |

513. Informix® extension

514. See [Expression on page 1193](#)515. See [Relational Operator on page 1429](#)516. See [IN Condition on page 1151](#)517. See [Quoted String on page 1424](#)

518. SPL trigger routines only

519. See [Trigger-Type Boolean Operator on page 1153](#)

| Element           | Description  | Restrictions                      | Syntax   |
|-------------------|--|-----------------------------------|--|
| <i>expression</i> | An SQL expression that returns a single value                      | Must return a single value        | <a href="#">Expression on page 1193</a>        |
| <i>string</i>     | A string delimited by single ( ' ) or double ( " ) quotation marks | Both delimiters must be identical | See <a href="#">Quoted String on page 1424</a> |

The following sections describe the different types of comparison conditions:

- [Relational-Operator Condition on page 1148](#)
- [BETWEEN Condition on page 1149](#)
- [IN Condition on page 1151](#)
- [IS NULL and IS NOT NULL Conditions on page 1152](#)
- [LIKE and MATCHES Condition on page 1154.](#)

For a discussion of comparison conditions in the context of the SELECT statement, see [Using a Condition in the WHERE Clause on page 813](#).

**Warning:** A literal DATE or DATETIME value in a comparison condition should specify 4 digits for the year. When you specify a 4-digit year, the **DBCENTURY** environment variable has no effect on the result. When you specify a 2-digit year, **DBCENTURY** can affect how the database server interprets the comparison condition, which might not work as you intended. For more information about **DBCENTURY**, see the *Informix® Guide to SQL: Reference*.

## Column Name

The Column Name segment can be an element in comparison conditions. The name of a column (or of one or more fields within a column of a ROW data type) is not the subject of the comparison, but the database server uses this SQL identifier to access the data value in the specified column or field of a row in a database table or view.

Column Name

*table.*

*view.*

*synonym.*

*alias .*

*column*

*row\_column*

<sup>520</sup>*.field*

520. Repeat no more than three times

| Element                     | Description                                  | Restrictions   | Syntax                                  |
|-----------------------------|--|--|---|
| <i>alias</i>                | Temporary alternative name for table or view | Must be defined in the FROM clause of the SELECT statement                             | <a href="#">Identifier on page 1456</a> |
| <i>column</i>               | Name of a column                             | Must exist in the specified table  | <a href="#">Identifier on page 1456</a> |
| <i>field</i>                | A field to compare in a ROW type column      | Must be a component of <i>row-column name</i> or <i>field name</i> (for nested rows)   | <a href="#">Identifier on page 1456</a> |
| <i>row_column</i>           | A column of type ROW                         | Must be an existing named ROW type or unnamed ROW type                                 | <a href="#">Identifier on page 1456</a> |
| <i>synonym, table, view</i> | Name of a synonym, table, or view            | The <i>synonym</i> and the table or view to which it points must exist in the database | <a href="#">Identifier on page 1456</a> |

For more information on the meaning of the *column* name in these conditions, see the [IS NULL and IS NOT NULL Conditions on page 1152](#) and the [LIKE and MATCHES Condition on page 1154](#).

## Quotation Marks in Conditions

When you compare a column expression with a constant expression in any comparison condition, observe the following rules:

- If the column has a numeric data type, do not enclose the constant expression between quotation marks.
- If the column has a character data type, enclose the constant expression between quotation marks.
- If the column has a time data type, enclose the constant expression between quotation marks.

Otherwise, you might get unexpected results.

The following example shows the correct use of quotation marks in comparison conditions. Here the **ship\_instruct** column has a character data type, the **order\_date** column has a date data type, and the **ship\_weight** column has a numeric data type.

```
SELECT * FROM orders
WHERE ship_instruct = 'express'
AND order_date > '05/01/98'
AND ship_weight < 30;
```

## Relational-Operator Condition

A relational operator compares two expressions quantitatively.

For a list of the supported relational operators and their descriptions, see [Relational Operator on page 1429](#).

The following examples show some relational-operator conditions:

```
city[1,3] = 'San'

o.order_date > '6/12/98'
```

```

WEEKDAY(paid_date) = WEEKDAY(CURRENT- (31 UNITS DAY))

YEAR(ship_date) < YEAR (TODAY)

quantity <= 3

customer_num <> 105

customer_num != 105

```

Operands in relational operator conditions cannot have UNKNOWN or NULL values. If an expression within the *condition* has an UNKNOWN value because it references an uninitialized variable, the database server raises an exception.

### Conditions testing for NULL values

If any expression within the *condition* evaluates to NULL, the *condition* cannot be true, unless you are explicitly testing for NULL by using the IS NULL operator. For example, if the **paid\_date** column has a NULL value, then neither of the following queries can retrieve that row:

```

SELECT customer_num, order_date FROM orders
  WHERE paid_date = '';

SELECT customer_num, order_date FROM orders
  WHERE NOT (paid_date != '');

```

You must use the IS NULL operator to test for a NULL value, as the next example shows.

```

SELECT customer_num, order_date FROM orders
  WHERE paid_date IS NULL;

```

The IS NULL operator and its logical inverse, the IS NOT NULL operator, are described in [IS NULL and IS NOT NULL Conditions on page 1152](#).

## BETWEEN Condition

Use the BETWEEN condition to test whether the value of a numeric, character, or time expression is within a specified range.

BETWEEN Condition

Expression<sup>521</sup>

**NOT**

**BETWEEN**

Expression<sup>521</sup>

**AND**

Expression<sup>521</sup>

### Usage

NULL values cannot satisfy the condition. Neither of the expressions that define the range can evaluate to NULL.

The three expressions in a BETWEEN condition must satisfy these restrictions:

521. See [Expression on page 1193](#)

- All three expressions must evaluate to mutually compatible numeric, time, or character data types.
- The value of the expression that immediately follows the `BETWEEN` keyword must be less than the value of the expression that follows the `AND` keyword.

### Numeric and time expressions in BETWEEN conditions

For number expressions, *less than* means to the left on the real line.

For DATE and DATETIME expressions, *less than* means earlier in time.

For INTERVAL expressions, *less than* means a shorter span of time.

### Character expressions in BETWEEN conditions

For CHAR, VARCHAR, and LVARCHAR expressions, *less than* means *before* in code-set order.

For NCHAR and NVARCHAR expressions, *less than* means *before* in the localized collation order, if one exists; otherwise, *less than* means *before* in code-set order.

Locale-based collation order, if one is defined for the locale, is used for NCHAR and NVARCHAR expressions. So for NCHAR and NVARCHAR expressions, *less than* means *before* in the locale-based collation order. For more information on locale-based collation order and the NCHAR and NVARCHAR data types, see the *Informix® GLS User's Guide*.

For information on how relational operator expressions with NCHAR and NVARCHAR operands in databases that have the NLCASE INSENSITIVE property differ from their behavior in databases that are case sensitive, see the topic [NCHAR and NVARCHAR expressions in case-insensitive databases on page 1174](#).

### The NOT keyword in BETWEEN conditions

For a BETWEEN condition to be `TRUE` depends on whether you include the `NOT` keyword.

- If you omit the `NOT` keyword, the BETWEEN condition is `TRUE` only if the value of the expression on the left of the `BETWEEN` keyword is in the inclusive range of the values of the two expressions on the right of the `BETWEEN` keyword.
- If the `NOT` keyword immediately precedes the `BETWEEN` keyword, the BETWEEN condition is `TRUE` only if the value of the expression on the left of the `BETWEEN` keyword is not in the inclusive range of the values of the two expressions on the right of the `BETWEEN` keyword.

Otherwise, the BETWEEN condition is `FALSE`.

### Examples of BETWEEN conditions

The following examples illustrate BETWEEN conditions:

```
order_date BETWEEN '6/1/97' and '9/7/97'

zipcode NOT BETWEEN '94100' and '94199'

EXTEND(call_dtime, DAY TO DAY) BETWEEN
  (CURRENT - INTERVAL(7) DAY TO DAY) AND CURRENT

lead_time BETWEEN INTERVAL (1) DAY TO DAY
  AND INTERVAL (4) DAY TO DAY
```

```
unit_price BETWEEN loprice AND hiprice
```

## IN Condition

The IN condition is satisfied when the expression to the left of the keyword IN is included in the list of items.

IN Condition

Expression<sup>522</sup>

**NOT**

**IN**

(

,

Literal Number<sup>523</sup>

Literal DATETIME<sup>524</sup>

Quoted String<sup>525</sup>

Literal INTERVAL<sup>526</sup>

**USER CURRENT\_USER TODAY**

**CURRENT**

DATETIME Field Qualifier<sup>527</sup>

**SITENAME DBSERVERNAME**

Literal Row<sup>527</sup>

)

*collection\_col*

(

, Literal Collection<sup>528</sup>

)

Literal Collection<sup>528</sup>

| Element               | Description   | Restrictions                                 | Syntax                                  |
|-----------------------|---|--|---|
| <i>collection_col</i> | Name of a collection column that is used in an IN condition | The column must exist in the specified table | <a href="#">Identifier on page 1456</a> |

522. See [Expression on page 1193](#)

523. See [Literal Number on page 1419](#)

524. See [Literal DATETIME on page 1414](#)

525. See [Quoted String on page 1424](#)

526. See [Literal INTERVAL on page 1418](#)

527. See [DATETIME Field Qualifier on page 1191](#)

528. See [Literal Row on page 1421](#)

529. See [Literal Collection on page 1412](#)

If you specify the NOT operator, the IN condition is `TRUE` when the expression is not in the list of items. NULL values do not satisfy the IN condition.

The following examples show some IN conditions:

```
WHERE state IN ('CA', 'WA', 'OR')
WHERE manu_code IN ('HRO', 'HSK')
WHERE user_id NOT IN (USER)
WHERE order_date NOT IN (TODAY)
```

In Informix® ESQL/C, the built-in TODAY function is evaluated at execution time. The built-in CURRENT function is evaluated when a cursor opens or when the query executes, if it is a singleton SELECT statement.

The built-in USER function is case sensitive; for example, it interprets **minnie** and **Minnie** as different values.

## Using the IN operator with collection data types

You can use the IN operator to determine if an element is contained in a collection.

The collection can be a simple or nested collection. (In a *nested* collection type, the element type of the collection is also a collection type.) When you use IN to search for an element of a collection, the expression to the left or right of the IN keyword cannot contain a BYTE or TEXT data type.

Suppose you create the following table that contains two collection columns:

```
CREATE TABLE tab_coll
(
  set_num SET(INT NOT NULL),
  list_name LIST(SET(CHAR(10) NOT NULL) NOT NULL)
);
```

The following statement fragments show how you might use the IN operator for search conditions on the collection columns of the **tab\_coll** table:

```
WHERE 5 IN set_num
WHERE 5.0::INT IN set_num
WHERE "5" NOT IN set_num
WHERE set_num IN ("SET{1,2,3}", "SET{7,8,9}")
WHERE "SET{'john', 'sally', 'bill'}" IN list_name
WHERE list_name IN ("LIST{""SET{'bill','usha'}"",
  ""SET{'ann' 'moshi'}""},
  "LIST{""SET{'bob','ramesh'}"",
  ""SET{'bomani' 'ann'}""}")
```

In general, when you use the IN operator on a collection data type, the database server checks whether the value on the left of the IN operator is an element in the set of values on the right of the IN operator.

## IS NULL and IS NOT NULL Conditions

The IS NULL condition is satisfied if the term that immediately precedes the IS keyword specifies one of the following undefined values:

- The name of a *column* that contains a null value.
- An *expression* that evaluates to null.

Conversely, if you use the IS NOT NULL operator, the condition is satisfied when the *column* contains a value that is not null, or when the *expression* that immediately precedes the IS NOT NULL keywords does not evaluate to null.

Suppose that you wish to perform an arithmetic computation on a column that can contain NULL values. You can create a table, insert values into the table, and then perform a query that uses a generic CASE expression that converts null values to 0 for the purpose of arithmetic calculations:

```
CREATE TABLE employee (emp_id INT, savings_in_401k INT, total_salary INT);

INSERT INTO employee VALUES(1, 5000, 40000);
INSERT INTO employee VALUES(2, 0, 40000);
INSERT INTO employee VALUES(3, NULL, 100000);

SELECT emp_id, savings_in_401k AS employer_match FROM employee WHERE
    CASE WHEN(savings_in_401k IS NULL) THEN 0
         ELSE savings_in_401k END * 0.06 > 0;
```

This example shows that by using IS NULL in the CASE expression, you can provide a value for the entries that otherwise are not computable because null is not a valid numeric value.

The IS NULL condition is satisfied if the column contains a null value or if the expression cannot be evaluated because it contains one or more null values. If you use the IS NOT NULL operator, the condition is satisfied when the operand is column value that is not null, or an expression that does not evaluate to null.

## Trigger-Type Boolean Operator

The trigger-type Boolean operators of Informix® can test at runtime whether the currently executing triggered action was triggered by the specified type of DML event. These operators take no operands.

Trigger-Type Boolean Operator

### **DELETING INSERTING SELECTING UPDATING**

These operators return TRUE ('t') if the triggering event of the currently executing trigger is the DML operation corresponding to the name of the operator, and they return FALSE ('f') otherwise. These operators are valid in IF statements, in CASE expressions, and in other contexts within an SPL trigger routines where a Boolean condition is valid.

For example, in the following statement fragment, the LET statement in the first THEN clause is executed only if the currently executing trigger was activated by an INSERT event, and the LET statement in the second THEN clause is executed only if the trigger was activated by a DELETE event:

```
IF (INSERTING = 't') THEN
    LET square = NEW.X * NEW.X
ELIF (DELETING = 't') THEN
    LET square = 0
```

The SELECTING, DELETING, INSERTING, and UPDATING operators are valid only in trigger UDRs that are invoked in the FOR EACH ROW triggered action of a trigger on a table, or (for the DELETING, INSERTING, and UPDATING operators) of an INSTEAD OF trigger on a view. An error is issued if you attempt to use a trigger-type Boolean operator in any other context.

If a trigger routine is invoked by a Delete, Insert, or Update trigger that the MERGE statement has activated,

- DELETING returns TRUE while MERGE is deleting a row from the target table.
- INSERTING returns TRUE while MERGE is inserting a row into the target table.
- UPDATING returns TRUE while MERGE is updating a row of the target table.

## LIKE and MATCHES Condition

A LIKE or MATCHES condition tests for matching character strings.

The condition is `TRUE`, or satisfied, when either of the following tests is `TRUE`:

- The value of the column on the left matches the pattern that the quoted string specifies. You can use wildcard characters in the string. NULL values do not satisfy the condition.
- The value of the column on the left matches the pattern that the column on the right specifies. The value of the column on the right serves as the matching pattern in the condition.

If the quoted string includes literal characters that match any of the wildcard characters that the LIKE or MATCHES operator recognizes, the ESCAPE clause can define an ASCII character that you can include in the quoted string. When the column value on the left is compared to the quoted string, the next character that immediately follows this *escape character* is interpreted as a literal character, rather than as a wildcard, and the escape character is ignored. The LIKE and MATCHES operators recognize different wildcard characters. For more information about LIKE and MATCHES escape characters, see [ESCAPE with LIKE on page 1157](#) and [ESCAPE with MATCHES on page 1157](#) topics.

You can use the single quotation mark ( `'` ) only with the quoted string to match a literal single quotation mark; you cannot use the ESCAPE clause. You can use the single quotation mark character as the escape character in matching any other pattern if you write it as this: `' '' ''`.

**Important:** Columns that you specify in LIKE or MATCHES conditions should be simple character data types, like CHAR, LVARCHAR, NCHAR, NVARCHAR, or VARCHAR. You cannot, for example, specify a complex data type, such as a ROW-type column, in a LIKE or MATCHES condition. (A ROW-type column is a column that is declared as a named or unnamed ROW type.) Similarly, the database server cannot evaluate a condition that uses LIKE or MATCHES with a simple or smart large object column, such as a CLOB column; a query that includes this condition fails with error -640.

## NOT Operator

The NOT operator makes the search condition successful when the column on the left has a value that is not NULL and that does not match the pattern that the quoted string specifies.

For example, the following conditions exclude all rows that begin with the characters `Baxter` in the **lname** column:

```
WHERE lname NOT LIKE 'Baxter%'
WHERE lname NOT MATCHES 'Baxter*'
```

## LIKE Operator

LIKE is the ANSI/ISO standard operator for comparing a column value to another column value, or to a quoted string.

The LIKE operator supports these wildcard characters in the quoted string.

### Wildcard

#### Effect

%

Matches zero or more characters

-

Matches any single character

Besides % and \_ LIKE supports a third wildcard character when both the DEFAULTESCCHAR configuration parameter and the DEFAULTESCCHAR session environment variable are not set:

### Wildcard

#### Effect

\

Removes the special significance of the next character (to match a literal % or \_ or \ by specifying \% or \%\_ or \% \

\)

Using the backslash (\) symbol as the default escape character (when DEFAULTESCCHAR is not set) is the Informix® extension to the ANSI/ISO-standard for SQL. You can specify backslash (\) symbol or some other ASCII character as the default escape character by setting the DEFAULTESCCHAR value to that character. For more information, see [DEFAULTESCCHAR session environment option on page 917](#).

In an ANSI-compliant database, you can only use the LIKE escape character to escape a percent sign (%), an underscore (\_), or the escape character itself.

The following condition tests the **description** column for the string `tennis`, alone or in a longer string, such as `tennis ball` or `table tennis paddle`:

```
WHERE description LIKE '%tennis%' ESCAPE '\'
```

The next example tests **description** for rows containing an underscore character. Here the backslash (\) escape character is necessary because underscore (\_) is a wildcard character.

```
WHERE description LIKE '%\_%' ESCAPE '\'
```

The LIKE operator has an associated operator function called **like()**. You can define a **like()** function to handle your own user-defined data types. See also *Informix® User-Defined Routines and Data Types Developer's Guide*.

## MATCHES Operator

The MATCHES operator is the Informix® extension for comparing a column value to another column value, or to a quoted string.

The MATCHES operator supports these wildcard characters in the quoted string.

### Wildcard

#### Effect

\*

Matches any string of zero or more characters

?

Matches any single character

[...]

Matches any of the enclosed characters, including ranges, as in [a-z]. Characters within the brackets cannot be escaped.

^

As first character within the brackets, matches any character that is not listed. Thus, [^abc] matches any character except a, b, or c.

\

Removes the special significance of the next character (to match a literal \ or any other wildcard by specifying \ \ or \\* or \? and so forth)

The following condition tests for the string `tennis`, alone or within a longer string, such as `tennis ball` or `table tennis paddle`:

```
WHERE description MATCHES '*tennis*'
```

The following condition is `TRUE` for the names `Frank` and `frank`:

```
WHERE fname MATCHES '[Ff]rank'
```

The following condition is `TRUE` for any name that begins with either `F` or `f`:

```
WHERE fname MATCHES '[Ff]*'
```

The next condition is `TRUE` for any name that ends with the letters `a`, `b`, `c`, or `d`:

```
WHERE fname MATCHES '*[a-d]'
```

MATCHES has an associated `matches()` operator function. You can define a `matches()` function for your own user-defined data types. For more information, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

If `DB_LOCALE` or `SET COLLATION` specifies a nondefault locale supporting a localized collation, and you specify a range for the MATCHES operator using bracket ([...]) symbols, the database server uses the localized collating order, instead of code-set order, to interpret the range and to compare values that have `CHAR`, `CHARACTER VARYING`, `LVARCHAR`, `NCHAR`, `NVARCHAR`, and `VARCHAR` data types.

This behavior is an exception to the usual rule that only NCHAR and NVARCHAR data types can be compared in a localized collating order. For more information on the GLS aspects of conditions that include the MATCHES or LIKE operators, see the *Informix® GLS User's Guide*.

In a NLSCASE INSENSITIVE database, comparison operations on NCHAR and NVARCHAR data disregard lettercase differences, so that the database server treats case variants among strings composed of same sequence letters as duplicates. All pairs of the following strings return TRUE as operands of the MATCHES operator:

```
'beta' 'Beta' 'BETA' 'bETa' 'betA' 'BetA'
```

For more information, see [Duplicate rows in NLSCASE INSENSITIVE databases on page 779](#) and [NCHAR and NVARCHAR expressions in case-insensitive databases on page 1174](#).

## ESCAPE with LIKE

The ESCAPE clause can specify an escape character that is different from the default escape character. The default escape character is set by the DEFAULTESCCHAR configuration parameter or the **DEFAULTESCCHAR** session environment option.

For example, if you specify `z` in the ESCAPE clause, then a quoted string operand that included `z_` is interpreted as including a literal underscore (`_`) character, rather than `_` as a wildcard. Similarly, `z%` is interpreted as a literal percent (`%`) sign, rather than `%` as a wildcard. Finally, the characters `zz` in a string would be interpreted as single literal `z`. The following statement retrieves rows from the **customer** table in which the **company** column includes a literal underscore character:

```
SELECT * FROM customer WHERE company LIKE '%z_%' ESCAPE 'z';
```

You can also use a host variable that contains a single character. The next statement uses a host variable to specify an escape character:

```
EXEC SQL BEGIN DECLARE SECTION;
char escp='z';
char fname[20];
EXEC SQL END DECLARE SECTION;
EXEC SQL select fname from customer
into :fname where company like '%z_%' escape :escp;
```

## ESCAPE with MATCHES

The ESCAPE clause can specify an escape character that is different from the default escape character. The default escape character is set by the DEFAULTESCCHAR configuration parameter or the **DEFAULTESCCHAR** session environment option.

Use this as you would the default escape character, the backslash, to include a question mark (`?`), an asterisk (`*`), a caret (`^`), or a left (`[`) or right (`]`) bracket as a literal character within the quoted string, to prevent them from being interpreted as special characters. If you choose to use `z` as the escape character, the characters `z?` in a string stand for a literal question mark (`?`). Similarly, the characters `z*` stand for a literal asterisk (`*`). Finally, the characters `zz` in the string stand for the single character `z`.

The following example retrieves rows from the **customer** table in which the value of the **company** column includes the question mark (`?`):

```
SELECT * FROM customer WHERE company MATCHES '*z?*' ESCAPE 'z';
```

## Stand-Alone Condition

A stand-alone condition can be any expression that is not explicitly listed in the syntax for the comparison condition. Such an expression is valid as a condition only if it returns a BOOLEAN value. For example, the following example returns a value of the BOOLEAN data type:

```
funcname(x)
```

## Condition with Subquery

Include a SELECT statement within a condition specifies a condition with subquery. You can use a subquery in a SELECT, INSERT, DELETE, or UPDATE statement to perform tasks like the following:

- Compare an expression to the result of the query.
- Determine if an expression is included in the results of the query.
- Ask whether the query selects any rows.

Condition with Subquery

EXISTS Subquery<sup>530</sup>

IN Subquery<sup>531</sup>

ALL, ANY, SOME Subquery<sup>532</sup>

The subquery can depend on the current row that the outer SELECT statement is evaluating; in this case, the subquery is called a *correlated subquery*. (For a discussion of correlated subqueries and their impact on performance, see the *Informix® Guide to SQL: Tutorial*.)

The following sections describe subquery conditions and their syntax.

- For a discussion of types of subquery conditions in the context of the SELECT statement, see [Using a Condition in the WHERE Clause on page 813](#).
- For a discussion of types of subquery conditions in the context of the INSERT statement, see [Subset of SELECT Statement on page 650](#).
- For a discussion of types of subquery conditions in the context of the DELETE statement, see [Subqueries in the WHERE Clause of DELETE on page 491](#).
- For a discussion of types of subquery conditions in the context of the UPDATE statement, see [Subqueries in the WHERE Clause of UPDATE on page 1050](#).

A subquery can return a single value, no value, or a set of values, depending on its context. If a subquery returns a value, it must select only a single column. If the subquery simply checks whether a row (or rows) exists, it can select any number of rows and columns.

530. See [EXISTS Subquery condition on page 1160](#)

531. See [IN Subquery on page 1159](#)

532. See [ALL, ANY, and SOME Subqueries on page 1161](#)

A subquery cannot reference BYTE or TEXT columns, nor can it contain an ORDER BY clause. A subquery that specifies a table expression in the FROM clause, however, can include the ORDER BY clause.

A subquery and its outer DML statement operate on the same table object if the FROM clause of the subquery specifies the same table or view that the outer statement references in one of these clauses:

- in the FROM clause of the DELETE or SELECT statement
- in the INTO clause of the INSERT statement
- in the Table Options or Collection Derived Table specification of the UPDATE statement.

Subqueries that return more than one row and that operate on the same table or view as the enclosing DML statement are valid only in the WHERE clause of the DELETE or UPDATE statement. Even in this context, such subqueries return error -360 unless all of the following conditions are satisfied:

- The subquery does not reference any column name in its FROM list that is in a table not specified in the projection list
- The subquery is specified using the Condition with Subquery syntax.
- Any SPL routines within the subquery cannot reference the table that is being modified.

The following program fragment includes examples of conditions with subqueries in UPDATE and DELETE statements:

```
CREATE TABLE t1 ( a INT, a1 INT)
CREATE TABLE t2 ( b INT, b1 INT) ;
. . .
UPDATE t1 SET a = a + 10 WHERE EXISTS
  (SELECT a FROM t1 WHERE a > 1);
UPDATE t1 SET a = a + 10 WHERE a IN
  (SELECT a FROM t1, t2 WHERE a > b
   AND a IN
    (SELECT a FROM t1 WHERE a > 50 ) );
DELETE FROM t1 WHERE EXISTS
  (SELECT a FROM t1);
```

For more information about subqueries in the DELETE statement, see [Subqueries in the WHERE Clause of DELETE on page 491](#).

For more information about subqueries in the UPDATE statement, see [Subqueries in the WHERE Clause of UPDATE on page 1050](#).

## IN Subquery

An IN subquery condition is `TRUE` if the value of the expression matches one or more of the values from the subquery. (The subquery must return only one row, but it can return more than one column.) The keyword IN is equivalent to the =ANY specification. The keywords NOT IN are equivalent to the !=ALL specification. See the [ALL, ANY, and SOME Subqueries on page 1161](#).

IN Subquery

Expression<sup>533</sup>**NOT****IN***(subquery)*

| Element         | Description    | Restrictions                                     | Syntax                                       |
|-----------------|----------------|--|--|
| <i>subquery</i> | Embedded query | Cannot contain the FIRST nor the ORDER BY clause | <a href="#">SELECT statement on page 768</a> |

The following example of an IN subquery finds the order numbers for orders that do not include baseball gloves (`stock_num = 1`):

```
WHERE order_num NOT IN
  (SELECT order_num FROM items WHERE stock_num = 1)
```

Because the IN subquery tests for the presence of rows, duplicate rows in the subquery results do not affect the results of the main query. Therefore, the UNIQUE or DISTINCT keyword in the subquery has no effect on the query results, although not testing duplicates can improve query performance.

## EXISTS Subquery condition

An EXISTS subquery condition evaluates to `TRUE` if the subquery returns a row. With an EXISTS subquery, one or more columns can be returned. The subquery always contains a reference to a column of the table in the main query. If you use an aggregate function in an EXISTS subquery that includes no HAVING clause, at least one row is always returned.

EXISTS Subquery

**NOT****EXISTS***(subquery)*

| Element         | Description    | Restrictions                                     | Syntax                                       |
|-----------------|----------------|--|--|
| <i>subquery</i> | Embedded query | Cannot contain the FIRST nor the ORDER BY clause | <a href="#">SELECT statement on page 768</a> |

The following example of a SELECT statement with an EXISTS subquery returns the stock number and manufacturer code for every item that has never been ordered (and is therefore not listed in the `items` table). You can appropriately use an EXISTS subquery in this SELECT statement because you use the subquery to test both `stock_num` and `manu_code` in `items`.

```
SELECT stock_num, manu_code FROM stock
WHERE NOT EXISTS (SELECT stock_num, manu_code FROM items
  WHERE stock.stock_num = items.stock_num AND
  stock.manu_code = items.manu_code);
```

533. See [Expression on page 1193](#)

The preceding example works equally well if you use `SELECT *` in the subquery in place of the column names, because the existence of the entire row is tested; specific column values are not tested.

## ALL, ANY, and SOME Subqueries

Use the `ALL`, `ANY`, and `SOME` keywords to specify what makes the condition `TRUE` or `FALSE`. A search condition that is `TRUE` when the `ANY` keyword is used might not be `TRUE` when the `ALL` keyword is used, and vice versa.

ALL, ANY, SOME Subquery

Expression<sup>534</sup>

Relational Operator<sup>535</sup>

**ALL ANY SOME**

(*subquery*)

| Element         | Description    | Restrictions  | Syntax                                       |
|-----------------|----------------|---|--|
| <i>subquery</i> | Embedded query | Cannot contain the <code>FIRST</code> or the <code>ORDER BY</code> clause | <a href="#">SELECT statement on page 768</a> |

## Using the ALL Keyword

The `ALL` keyword specifies that the search condition is `TRUE` if the comparison is `TRUE` for every value that the subquery returns. If the subquery returns no value, the condition is `TRUE`.

In the following example, the first condition tests whether each `total_price` is greater than the total price of every item in order number 1023. The second condition uses the `MAX` aggregate function to produce the same results.

```
total_price > ALL (SELECT total_price FROM items
                  WHERE order_num = 1023)

total_price > (SELECT MAX(total_price) FROM items
              WHERE order_num = 1023)
```

Using the `NOT` keyword with an `ALL` subquery tests whether an expression is not `TRUE` for at least one element that the subquery returns. For example, the following condition is `TRUE` when the expression `total_price` is not greater than all the selected values. That is, it is `TRUE` when `total_price` is not greater than the highest total price in order number 1023.

```
NOT total_price > ALL (SELECT total_price FROM items
                    WHERE order_num = 1023)
```

## Using the ANY or SOME Keywords

The `ANY` keyword denotes that the search condition is `TRUE` if the comparison is `TRUE` for at least one of the values that is returned. If the subquery returns no value, the search condition is `FALSE`. The `SOME` keyword is a synonym for `ANY`.

The following conditions are `TRUE` when the total price is greater than the total price of at least one of the items in order number 1023. The first condition uses the `ANY` keyword; the second uses the `MIN` aggregate function:

534. See [Expression on page 1193](#)

535. See [Relational Operator on page 1429](#)

```
total_price > ANY (SELECT total_price FROM items
                   WHERE order_num = 1023)

total_price > (SELECT MIN(total_price) FROM items
              WHERE order_num = 1023)
```

Using the NOT keyword with an ANY subquery tests whether an expression is not `TRUE` for all elements that the subquery returns. For example, the following condition is `TRUE` when the expression **total\_price** is not greater than any selected value. That is, it is `TRUE` when **total\_price** is greater than none of the total prices in order number 1023.

```
NOT total_price > ANY (SELECT total_price FROM items
                      WHERE order_num = 1023)
```

## Omitting the ANY, ALL, or SOME Keywords

You can omit the keywords ANY, ALL, or SOME in a subquery if you know that the subquery will return exactly one value. If you omit the ANY, ALL, or SOME keywords, and the subquery returns more than one value, you receive an error. The subquery in the following example returns only one row because it uses an aggregate function:

```
SELECT order_num FROM items
       WHERE stock_num = 9 AND quantity =
             (SELECT MAX(quantity) FROM items WHERE stock_num = 9);
```

## NOT Operator

If you preface a condition with the keyword NOT, the test is `TRUE` only if the condition that NOT qualifies is `FALSE`. If the condition that NOT qualifies has a NULL or an UNKNOWN value, the NOT operator has no effect.

The following truth table shows the effect of NOT with 3-valued Boolean operands. Here T represents a `TRUE` condition, F represents a `FALSE` condition, and a question mark (?) represents an `UNKNOWN` condition. (An `UNKNOWN` value can occur when an operand is NULL).

| NOT |   |
|-----|---|
| T   | F |
| ?   | ? |
| F   | T |

The left column shows the value of the operand of the NOT operator, and the right column shows the returned value after NOT is applied to the operand.

## Conditions with AND or OR

You can combine simple conditions with the logical operators AND or OR to form complex conditions.

The following SELECT statements contain examples of complex conditions in their WHERE clauses:

```
SELECT customer_num, order_date FROM orders
       WHERE paid_date > '1/1/97' OR paid_date IS NULL;
SELECT order_num, total_price FROM items
       WHERE total_price > 200.00 AND manu_code LIKE 'H'
```

```
SELECT lname, customer_num FROM customer
WHERE zipcode BETWEEN '93500' AND '95700'
OR state NOT IN ('CA', 'WA', 'OR');
```

The following truth tables show the effect of the AND and OR operators. The letter T represents a `TRUE` condition, F represents a `FALSE` condition, and the question mark (?) represents an `UNKNOWN` value. An `UNKNOWN` value can occur when part of an expression that uses a logical operator is `NULL`.

| OR | T | ? | F | AND | T | ? | F |
|----|---|---|---|-----|---|---|---|
| T  | T | T | T | T   | T | ? | F |
| ?  | T | ? | ? | ?   | ? | ? | F |
| F  | T | ? | F | F   | F | F | F |

The marginal values at the left represent the first operand, and values in the top row represent the second operand. Values within each 3x3 matrix show the returned value after the operator is applied to operands of those values.

If the Boolean expression evaluates to `UNKNOWN`, the condition is not satisfied.

Consider the following example within a `WHERE` clause:

```
WHERE ship_charge/ship_weight < 5
AND order_num = 1023
```

The row where `order_num = 1023` is a row where `ship_weight` is `NULL`. Because `ship_weight` is `NULL`, `ship_charge/ship_weight` is also `NULL`; therefore, the truth value of `ship_charge/ship_weight < 5` is `UNKNOWN`. Because `order_num = 1023` is `TRUE`, the AND table states that the truth value of the entire condition is `UNKNOWN`. Consequently, that row is not chosen. If the condition used an OR in place of the AND, the condition would be `TRUE`.

## Data Type

The Data Type segment specifies the data type of a column, of a component of a collection, of a field within a ROW type, of a routine parameter, or of a value returned by an expression or by a cast function. Use this segment whenever you see a reference to a data type in a syntax diagram.

### Syntax

Data Type

Built-In Data Type<sup>537</sup>  
536

User-Defined Data Type<sup>538</sup>

Complex Data Type<sup>539</sup>

536. Informix® extension

537. See [Built-In Data Types on page 1164](#)

538. See [User-Defined Data Type on page 1183](#)

539. See [Complex Data Type on page 1186](#)

## Usage

Sections that follow summarize these data types. For more information, see the chapter about data types in the *Informix® Guide to SQL: Reference*.

## Built-In Data Types

Built-in data types are data types that are defined by the database server.

Built-In Data Type

**BOOLEAN** <sup>546</sup>

BSON and JSON data types <sup>545</sup>

Character Data Type <sup>541</sup>

Numeric Data Type <sup>542</sup>

540

Large-Object Data Type <sup>543</sup>

Time Data Type <sup>544</sup>

**IDSSECURITYLABEL** <sup>547</sup>

These data types are built into the database server in the sense that the information and support functions required to interpret and transfer these data types is part of the database server software, which supports *character*, *numeric*, *large-object*, and *time* categories of built-in data types.

## BOOLEAN and other built-in opaque data types

Informix® also supports the BOOLEAN data type, which is a *built-in opaque data type* that can store `true`, `false`, or NULL values. The symbol `t` represents a literal BOOLEAN `true` value, and `f` represents a literal BOOLEAN `false` value.

BOOLEAN, BSON, JSON, and LVARCHAR are the only built-in opaque data types that can be returned by cross-server distributed queries or by other cross-server distributed DML operations. Column values of other built-in opaque data types cannot be retrieved by a distributed query (nor modified by INSERT, DELETE, MERGE, or UPDATE operations on a remote database) unless all of the tables that the DML operation accesses are in databases of the local Informix® instance.

540. Informix® extension

541. See [Character Data Types on page 1170](#)

542. See [Numeric Data Types on page 1176](#)

543. See [Large-Object Data Types on page 1180](#)

544. See [Time Data Types on page 1182](#)

545. See [BSON and JSON built-in opaque data types on page 1165](#)

546. See [BOOLEAN and other built-in opaque data types on page 1164](#)

547. See [IDSSECURITYLABEL Data Type on page 1175](#)

Similarly, in UDRs that perform distributed operations on databases of other Informix® instances, BOOLEAN, BSON, JSON, and LVARCHAR are the only built-in opaque types that are valid as a parameter or as the returned data type of the UDR, which must be defined in all participating databases.

Besides the BOOLEAN type, other built-in opaque data types of Informix® include BLOB, , BSON, JSON, CLOB, LVARCHAR, IFX\_LO\_SPEC, IFX\_LO\_STAT, INDEXKEYARRAY, POINTER, RTNPARAMTYPES, SELFUNCARGS, STAT, CLIENTBINVAL, and XID data types. These built-in opaque types are supported in the local database and in distributed operations across databases of the same server instance. The first five of these types are discussed in subsequent sections of this chapter.

Informix® also supports the built-in opaque data types LOLIST, IMPEXP, IMPEXPBIN, and SENDRECV. These types cannot, however, be accessed in a remote database by DML operations, nor returned from a remote database by a UDR, because these data types do not have the required support functions. For more information about the data types that Informix® supports in distributed transactions, see [Data Types in Distributed Queries on page 779](#).

## BSON and JSON built-in opaque data types

The BSON and JSON data types are built-in opaque types of Informix® that can be accessed and manipulated in local and distributed queries and in other DML operations. These are SQL data types that directly support relational database operations on data in BSON or JSON document store format. However, if you plan to query JSON and BSON data through the wire listener, you must create your database objects, such as collections and indexes, through the wire listener. You can use SQL statements to query JSON and BSON data whether you created your database objects through the wire listener or with SQL statements.

JSON and BSON documents contain one or more fields, which are similar to columns, and values for fields. A JSON or BSON column can contain multiple documents, each similar to a row in a relational database. The data values in JSON and BSON documents can be numbers, strings, or Boolean values. Documents can be nested within documents.

The database server validates JSON or BSON documents that you insert into the database. The JSON data type contains plain text. The BSON data type is a binary format of the JSON data type. You can create a table column of either the JSON or the BSON data type, however, the BSON data type is better suited for storing structured data in an Informix® database. The database server can operate on data in BSON columns, but can only insert and display data in JSON columns.

JSON and BSON documents up to 4 KB are stored in-row. Documents that are greater than 4 KB in size are stored in the sbospace that is associated with the table, or the default sbospace if the table does not have a designated sbospace. The maximum size of a JSON or BSON document is 32 KB. The maximum size of a JSON or BSON column is limited only by the operating system.

[JSON data type on page 1166](#)

[BSON data type on page 1166](#)

[Supported SQL operations for BSON and JSON data types on page 1167](#)

[Restrictions on BSON and JSON data types on page 1169](#)

[Examples on page 1169](#)

## JSON data type

The JSON data type is a plain text format for entering and displaying structured data. JSON is named after the JavaScript Object Notation (JSON), a data-interchange format that is based on the object-literal notation of JavaScript.

A JSON document has the format:

Figure 10. JSON document

```
{
, field:
"value "
JSON document JSON array
}
JSON array
[
,
"value "
JSON document JSON array
]
```

| Element      | Description  |
|--------------|--|
| <i>field</i> | A string of Unicode characters that represents a field name. |
| <i>value</i> | A string of Unicode characters that represents a data value. |

JSON documents require the following notation:

- Braces ({ and }) surround each JSON document. JSON documents can be nested.
- A comma (,) separates field-value pairs.
- Double quotation marks (") delimit character values. Quotation marks are not necessary around numeric values.
- Brackets ([ and ]) surround arrays of values. Arrays can contain nested documents or arrays.

The following JSON document has a nested document and an array:

```
{ "person" : {
  "givenname" : "Jim",
  "surname" : "Flynn",
  "age" : 29,
  "cars" : [ "dodge", "olds" ]
}
```

## BSON data type

The BSON data type is the binary representation of a JSON data type format for serializing JSON documents.

When you insert JSON documents through the wire listener with MongoDB API commands, a BSON column that is named **data** is created in the specified collection. The MongoDB API command also automatically adds an ObjectId field-value pair. When you insert JSON and BSON documents through SQL statements or Informix® utilities, the documents do not contain ObjectIds unless you explicitly include them.

To create a BSON column in a table with an SQL statement, use the standard CREATE TABLE statement and specify a BSON column. The only valid default value for a BSON column is NULL.

The BSON data type differs from standard SQL data types in that you must cast the data or use built-in BSON processing functions:

- To insert data that is in plain text with an SQL statement into a BSON column, you must cast the data to JSON. If you do not provide the cast to JSON, the database server treats the document as a string.
- To view BSON data in a readable format when you select data from a BSON column with an SQL statement, you must either cast the column to JSON or use a BSON value function in a function expression. BSON value functions convert field values in BSON columns to standard SQL data types. You can use dot notation to select data from specific fields within the BSON column and a JSON cast to return the results in a readable format.
- To update BSON data with an SQL statement, use the BSON\_GET or the BSON\_UPDATE function.
- When you include a JSON document as an expression in an SQL statement that operates on a BSON column, you must cast the document to JSON and then to BSON.
- To create an index on a BSON field, use the BSON\_GET function and the USING BSON keywords as the index-key specification in the CREATE INDEX statement.

For more information, see BSON processing functions.

### Supported SQL operations for BSON and JSON data types

The following table lists supported DDL operations on BSON and JSON data types.

**Table 16. DDL operations on BSON and JSON data type**

| Operation   | Supported for BSON data type | Supported for JSON data type |
|---|------------------------------|------------------------------|
| Create a table or a temporary table with one or more columns of the data type or a distinct type of the data type | Yes                          | Yes                          |
| Alter a table to add a column of the data type  | Yes                          | Yes                          |
| Drop a column of the data type  | Yes                          | Yes                          |
| Create a B-tree index on a column of the data type  | No                           | No                           |
| Create an index or a functional index on a field  | Yes                          | No                           |

**Table 16. DDL operations on BSON and JSON data type (continued)**

| Operation  | Supported for BSON data type | Supported for JSON data type |
|--|------------------------------|------------------------------|
| Create a basic text search index on a column of the data type          | Yes                          | Yes                          |
| Truncate tables with columns of the data type                          | Yes                          | Yes                          |
| Fragment a table based on field values                                 | Yes                          | Yes                          |
| Create a view based on columns of the data type and field values       | Yes                          | No                           |
| Compress data in a column of the data type                             | Yes                          | Yes                          |
| Create a cast on the data type   | Yes                          | Yes                          |
| Create triggers on fields  | Yes                          | No                           |
| Include a column of the data type in a <b>TimeSeries</b> row data type | Yes                          | No                           |

The following table lists supported DML operations on BSON and JSON data types.

**Table 17. DML operations on BSON and JSON data**

| Operation   | Supported for BSON data type | Supported for JSON data type |
|---|------------------------------|------------------------------|
| Cast data   | Yes                          | Yes                          |
| Use a cursor to read data   | Yes                          | Yes                          |
| Select contents of column of the data type                              | Yes                          | Yes                          |
| Select field values with dot notation or with BSON processing functions | Yes                          | No                           |
| Update data   | Yes                          | No                           |
| Insert data   | Yes                          | Yes                          |
| Find the size of a field value  | Yes                          | No                           |
| Update statistics on a table with columns of the data type              | Yes                          | Yes                          |
| Merge tables based on field values                                      | Yes                          | No                           |
| Join tables based on field values                                       | Yes                          | No                           |

**Table 17. DML operations on BSON and JSON data (continued)**

| Operation   | Supported for BSON data type | Supported for JSON data type |
|---|------------------------------|------------------------------|
| Load and unload data with the LOAD and UNLOAD statements, external tables, the onload and onunload utilities, or the dbschema, dbexport, and dbimport utilities | Yes                          | Yes                          |
| Replicate data to Remote stand-alone secondary servers  | Yes                          | No                           |
| Shard data among Enterprise Replication servers   | Yes                          | No                           |

### Restrictions on BSON and JSON data types

The following operations are not supported for BSON or JSON data types:

- Encryption of BSON or JSON columns
- Table-level restore of tables that have BSON or JSON columns
- Capture data through the Change Data Capture API

### Examples

The examples use the following document:

```
{ "person" : {
  "givenname" : "Jim",
  "surname" : "Flynn",
  "age" : 29,
  "cars" : [ "dodge", "olds" ]
}
```

#### Example: Create a table with a BSON column

The following statements create a table with a BSON column and insert a document:

```
CREATE DATABASE testdb WITH LOG;
CREATE TABLE IF NOT EXISTS bson_table(bson_col BSON);

INSERT INTO bson_table VALUES(
  '{person:{givenname:"Jim",surname:"Flynn",age:29,cars:["dodge","olds"]}}'::JSON);
```

The document is explicitly cast to JSON and then implicitly cast to BSON.

#### Example: Select the whole BSON column

The following statement returns the contents of the BSON column:

```
SELECT bson_col::JSON FROM bson_table;
```

```
(expression)
{"person":{"givenname":"Jim","surname":"Flynn","age":29,"cars":["dodge","olds"]}}
```

If the column is not cast to JSON format, the returned data is in an unreadable binary format.

### Example: Select a field-value pair with dot notation

The following statement returns the value of the **surname** field:

```
SELECT bson_col.person.surname::JSON FROM bson_table;

(expression)
{surname:"Flynn"}
```

The dot notation uses the same format as *table\_name.column\_name*, but specifies a field within the column. The cast to JSON is necessary, and the returned value is a JSON document with the specified field-value pair.

### Example: Select a field value with a BSON value function

The following statement returns the value of the **surname** field:

```
SELECT BSON_VALUE_LVARCHAR(bson_col, "person.surname") FROM bson_table;

(expression)
Flynn
```

The `BSON_VALUE_LVARCHAR` function converts the value of the **surname** field to an `LVARCHAR` data type. A cast to JSON is not needed, and the returned value is only the value of the specified field.

### Example: Create an index on a BSON field

The following statement creates an index on the **surname** field in the BSON column:

```
CREATE INDEX idx2 ON bson_table(
  BSON_GET(bson_col, "person.surname")) USING BSON;
```

The `BSON_GET` function specifies that the **surname** field is indexed. The `USING BSON` keywords are necessary to specify that the index is created on a BSON column.

## Character Data Types

The character data types enable the database server to store text strings.

## Character Data Type

**CHAR CHARACTER**

<sup>548</sup>**NCHAR**

( 1 )

(size )

<sup>548</sup>**NVARCHAR**

**VARCHAR CHARACTER VARYING**

(max

, 0

,reserve

)

**LVARCHAR**

(2048 )

(max )

| Element        | Description   | Restrictions   | Syntax                                      |
|----------------|---|--|---|
| <i>max</i>     | Maximum size in bytes. For VARCHAR and NVARCHAR, this is required. LVARCHAR default is 2048 | VARCHAR and NVARCHAR: Integer; 1 <i>max</i> 255 (or 1 <i>max</i> 254, if indexed)<br>LVARCHAR: 1 <i>max</i> 32,739 | <a href="#">Literal Number on page 1419</a> |
| <i>reserve</i> | Bytes reserved. Default is 0.   | Integer; 0 <i>reserve max</i>  | <a href="#">Literal Number on page 1419</a> |
| <i>size</i>    | Size in bytes. Default is 1.  | Integer; 1 <i>size</i> 32,767  | <a href="#">Literal Number on page 1419</a> |

The database server issues an error if the data type declaration includes empty parentheses, such as LVARCHAR(). To declare a CHAR or LVARCHAR data type of the default length, simply omit any (*size*) or (*max*) specification. The CREATE TABLE statement of Informix® accepts VARCHAR and NVARCHAR column declarations that have no (*max*) nor (*max*, *reserve*) specifications, using ( 1, 0 ) as the (*max*, *reserve*) default values for the column.

The following table summarizes the built-in character data types.

| Data Type         | Description  |
|-------------------|--|
| CHAR              | Stores single-byte or multibyte text strings of fixed length (up to 32,767 bytes); supports code-set order in collation of text data. Default size is 1 byte.                                      |
| CHARACTER         | Synonym for CHAR   |
| CHARACTER VARYING | ANSI-compliant synonym for VARCHAR   |
| LVARCHAR          | Stores single-byte or multibyte text strings of varying length (up to 32,739 bytes). The size of other columns in the same table can further reduce this upper limit. Default size is 2,048 bytes. |

| Data Type | Description   |
|-----------|---|
| NCHAR     | Stores single-byte or multibyte text strings of fixed length (up to 32,767 bytes); supports localized collation of text data.     |
| NVARCHAR  | Stores single-byte or multibyte text strings of varying length (up to 255 bytes); supports localized collation of text data.      |
| VARCHAR   | Stores single-byte or multibyte text strings of varying length (up to 255 bytes); supports code-set order collation of text data. |

## Single-byte and multi-byte characters and locales

All built-in character data types can support single- and multibyte characters in the code set that the **DB\_LOCALE** setting specifies. Locales for most European and Middle Eastern languages support only single-byte code sets, but the **UTF-8** code set for the Unicode locale, and code sets for some East Asian locales, such as the Chinese **GB18030-2000** locale, support multibyte logical characters.

When the `SQL_LOGICAL_CHAR` configuration parameter is enabled, you can instruct the database server to interpret explicit or default size parameters in declarations of built-in character data types as specifying the number of logical characters that can be stored, rather than the number of bytes. These logical character semantics are also applied to `DISTINCT` types whose base types are built-in character types, and to fields of built-in character types in declarations of named or unnamed `ROW` data types. This feature does not, however, support user-defined data types (UDTs) that store character strings. For more information about this feature, see the description of the `SQL_LOGICAL_CHAR` configuration parameter.

The `TEXT` and `CLOB` data types also support single-byte or multibyte character data, but most built-in functions for manipulating character strings do not support `TEXT` nor `CLOB` data. For more information, see [Large-Object Data Types on page 1180](#).

## Fixed- and Varying-Length Character Data Types

The database server supports storage of fixed-length and varying-length character data. A *fixed-length* column requires the defined number of bytes regardless of the actual size of the data. The `CHAR` data type is of fixed-length. For example, a `CHAR(25)` column requires 25 bytes of storage for all values, so the string `This is a text string` uses 25 bytes of storage.

A *varying-length* column size can be the number of bytes occupied by its data. `NVARCHAR`, `VARCHAR`, and the `LVARCHAR` data types are varying-length character data types. For example, a `VARCHAR(25)` column reserves up to 25 bytes of storage for the column value, but the character string `This is a text string` uses only 21 bytes of the reserved 25 bytes. The `VARCHAR` data type can store up to 255 bytes of data. For information about the `IFX_PAD_VARCHAR` environment variable, whose setting controls how the database server sends and receives `VARCHAR` and `NVARCHAR` data values, see *Informix® Guide to SQL: Reference*.

Because of the maximum row size limit of 32,767 bytes, a single table cannot be created with more than approximately 195 varying-length or `ROW` type columns.

## Accessing large tables that have varying-length columns

For tables with more than a million rows, queries that use full-table scan or skip-scan access methods are more efficient if they perform light scans, rather than bufferpool scans. Light scans are not supported, however, on tables that include NVARCHAR, VARCHAR, or LVARCHAR data types columns, or columns of DISTINCT data types whose base types are a *varying-length* column, unless the BATCHEDREAD\_TABLE configuration parameter (or the BATCHEDREAD\_TABLE session environment option) is set to `1`.

### Restriction:

This dependency of light scans on BATCHEDREAD\_TABLE being enabled also applies to tables whose schema or storage attributes include any of the following:

- table compression
- columns of any variable-length data type
- rows that occupy more than a single page of storage.

For more information about when the query optimizer can choose execution paths that perform light scans to access large tables, see your *Informix® Performance Guide*.

## LVARCHAR Data Type

The LVARCHAR type of Informix® can store up to 32,739 bytes of text, but if you specify no size in an LVARCHAR data type declaration, the default length is 2,048 bytes. LVARCHAR is a built-in opaque data type. Unlike most of the built-in opaque types, LVARCHAR column values can be accessed in a database of a non-local Informix® instance in a distributed query or other DML operations, and LVARCHAR can be the data type of a parameter or of a returned value of a UDR that accesses data outside the local database.

Informix® uses the LVARCHAR data type in cross-server I/O operations on opaque data types. In this context, the maximum size of the LVARCHAR data value is limited only by the operating system.

Light scans during query execution are not supported on tables that include LVARCHAR columns, unless the BATCHEDREAD\_TABLE configuration parameter (or the BATCHEDREAD\_TABLE session environment option) is set to `1`.

## NCHAR and NVARCHAR data types

The character data types NCHAR and NVARCHAR can support a localized order of collation in some database locales. In databases created with the NLSCASE INSENSITIVE property, NCHAR and NVARCHAR columns (and string values that are cast to these data types) can support case-insensitive queries.

The character data types CHAR, LVARCHAR, and VARCHAR support *code-set order* collation of data. This is the order in which the characters are defined within in the code set of the database locale that the **DB\_LOCALE** environment variable

specifies. The default (U.S. English) locale is an example of a locale that uses the code-set order of collation for sorting CHAR, LVARCHAR, and VARCHAR string values.

For information on how the settings (or default values) of the **DB\_LOCALE**, **CLIENT\_LOCALE**, and **SERVER\_LOCALE** environment variables determine which locale is used for collation, see the *Informix® GLS User's Guide*.

Some locales, however, specify an order of collation that is not identical to the code-set order. To support any locale-specific order of collation, you can use the NCHAR and NVARCHAR data types. The NCHAR data type is a fixed-length character data type that supports localized collation. The NVARCHAR data type is a varying-length character data type that can store up to 255 bytes of text data and supports localized collation. In locales where the code set defines no localized order of collation, such as the default locale, there is no difference between the CHAR and NCHAR data types, nor between the VARCHAR and NVARCHAR data types, except in case-insensitive databases.

In databases created with the NLSCASE INSENSITIVE property, values of these data types are stored exactly as they are loaded into the database, but in data processing operations, including comparison and collation of NVARCHAR and NCHAR strings, the database server ignores letter case, ordering the data values without respect to or preference for case. For example, the NCHAR or NVARCHAR string "PH" might precede or follow "pH" or "ph" in the collated list, in which these three strings are considered duplicates, depending on the order in which these values are retrieved. For more information about NCHAR or NVARCHAR data processing in case-insensitive databases, see [Specifying NLSCASE case sensitivity on page 206](#), [Duplicate rows in NLSCASE INSENSITIVE databases on page 779](#), and [NCHAR and NVARCHAR expressions in case-insensitive databases on page 1174](#).

For NCHAR or NVARCHAR values, the SET COLLATION statement of SQL can override the localized collation order of the current session by specifying another locale. Indexes on NCHAR or NVARCHAR columns sort values according to the localized collation order that was in effect when the index was created, if that is different from the current collation order. For more information about how the SET COLLATION statement can affect the sorting behavior of indexes, constraints, cursors, prepared objects, and SPL routines, see [Collation Performed by Database Objects on page 864](#).

If you specify no parameters in CREATE TABLE or ALTER TABLE statements that declare VARCHAR or NVARCHAR columns, then the new columns default to a *max* size of 1 byte and a *reserve* size of zero.

## NCHAR and NVARCHAR expressions in case-insensitive databases

In databases created with the NLSCASE INSENSITIVE property, the database server makes no distinction between uppercase and lowercase variants of the same letter in NCHAR and NVARCHAR expressions, regardless of whether a localized collation order is defined for the locale.

This disregard for letter case can change the values that case-insensitive operations on NCHAR or NVARCHAR expressions return, compared to the same operations on the same expressions in a case-sensitive database, if letter case variants are the only differences among the operands of relational operators, or among the arguments to string functions.

Suppose, for example, that for a record in a table of a database in the default locale, the NCHAR column **lname** stores the value `McDavid`.

In a case-sensitive database, the Boolean expression `lname > "MCDAVID"` evaluates as true, because the database server uses the codeset order of the default locale to compare the two operands. Although both strings begin with uppercase `M`, the next character in the column value is lowercase `c`, the ASCII 99 code point, but the next character in the quoted string is uppercase `C`, the ASCII 67 code point. Because 99 is greater than 67, the column value is greater than the quoted string in a case-sensitive database.

In a case-insensitive database, however, the same expression `lname > "MCDAVID"` evaluates as false, because the database server ignores letter case variants when it compares the two operands. Both strings have the same letters in the same sequence, so by these criteria, the column value is identical to the quoted string.

Because a database that has the `NLSCASE INSENSITIVE` property disregards letter case in comparisons that include an `NCHAR` or `NVARCHAR` operand, operations on `NCHAR` or `NVARCHAR` character strings in case-insensitive databases can produce results that differ from those of a case-sensitive database. Contexts in which a case-sensitive database and a case-insensitive database might use the same SQL operations to return different results from the same data set include these:

- sorting and collation
- foreign key and primary key dependencies
- enforcing unique constraints
- clustered indexes
- access-method optimizer directives
- queries with `WHERE` predicates
- queries with `UNIQUE` or `DISTINCT` in the projection clauses
- queries with `ORDER BY` clauses
- queries with `GROUP BY` clauses
- cascading `DELETE` operations
- table or index storage distribution `BY EXPRESSION`
- table or index storage distribution `BY LIST`
- data distributions from `UPDATE STATISTICS` operations.

## IDSSECURITYLABEL Data Type

In a table that is protected by a label-based security policy, the `IDSSECURITYLABEL` data type of Informix® stores a security label.

Only a user who holds the `DBSECADM` role can create, alter, or drop a column of this data type. This is a built-in `DISTINCT OF VARCHAR(128)` data type, but it is not classified as a character data type because its use is restricted to label-based access control. A table that has a security policy can have no more than one `IDSSECURITYLABEL` column, and a table that is associated with no security policy can have none.

The `DBSECADM` can use the `GRANT` statement to associate a specific security label with a user, and the `REVOKE` statement can cancel a security label that a user holds. For a given security policy, a user can have no more than one label that supports both read and write access, or no more than one label for write access and no more than one label for read access. For data protected by a security policy, but for which the user has been granted discretionary access privileges, the database server

determines whether a specific user can access the data by comparing the security label of the data with the security label of the user, while also taking into consideration any exemptions to the security policy rules that the user holds.

For information on how to specify an `IDSSECURITYLABEL` value, see [Security Label Support Functions on page 1294](#).

For a discussion of security policies, security components, security labels, and other concepts of label-based access control (LBAC), see the Informix® Security Guide.

## Numeric Data Types

Numeric data types enable the database server to store numbers such as integers and real numbers in a column.

Numeric Data Type

Exact Numeric Data Type<sup>549</sup>

Approximate Numeric Data Type<sup>550</sup>

The values of numbers are stored either as *exact numeric* data types or as *approximate numeric* data types.

## Exact Numeric Data Types

An *exact numeric* data type stores numbers of a specified precision and scale.

549. See [Exact Numeric Data Types on page 1176](#)

550. See [Approximate Numeric Data Types on page 1179](#)

Exact Numeric Data Type

(*start* )

| Element          | Description               | Restrictions   | Syntax                                      |
|------------------|---------------------------|--|---|
| <i>precision</i> | Significant digits        | Must be an integer; 1 <i>precision</i> 32  | <a href="#">Literal Number on page 1419</a> |
| <i>scale</i>     | Digits in fractional part | Must be an integer; 1 <i>scale precision</i>   | <a href="#">Literal Number on page 1419</a> |
| <i>start</i>     | Integer starting value    | For SERIAL: 1 <i>start</i> 2,147,483,64; For BIGSERIAL and SERIAL8: 1 <i>start</i> 9,223,372,036,854,775,807 | <a href="#">Literal Number on page 1419</a> |

The *precision* of a data type is the number of digits that the data type stores. The *scale* is the number of digits to the right of the decimal separator.

The following table summarizes the exact numeric data types available.

| Data Type             | Description  |
|-----------------------|--|
| DEC( <i>p,s</i> )     | Synonym for DECIMAL( <i>p,s</i> )  |
| DECIMAL( <i>p,s</i> ) | Stores fixed-point decimal values of real numbers, with up to 30 significant digits in the fractional part, or up to 32 significant digits to the left of the decimal point. |

551. Informix® extension

| Data Type             | Description   |
|-----------------------|---|
| INT                   | Synonym for INTEGER   |
| INTEGER               | Stores a 4-byte integer value. These values can be in the range from $-(2^{31}-1)$ to $2^{31}-1$ (from -2,147,483,647 to 2,147,483,647).  |
| BIGINT and INT8       | Stores an 8-byte integer value. These values can be in the range from $-(2^{63}-1)$ to $2^{63}-1$ (the range -9,223,372,036,854,775,807 to 9,223,372,036,854,775,807). BIGINT has storage and processing advantages over INT8.  |
| MONEY( <i>p,s</i> )   | Stores fixed-point currency values. These values have same internal data format as a fixed-point DECIMAL( <i>p,s</i> ) value.   |
| NUMERIC( <i>p,s</i> ) | ANSI-compliant synonym for DECIMAL( <i>p,s</i> )  |
| SERIAL                | Stores a 4-byte positive integer that the database server generates. Values can range from 1 to $2^{31}-1$ (that is, from 1 to 2,147,483,647).  |
| BIGSERIAL and SERIAL8 | Stores an 8-byte positive integer value that the database server generates. Values can range from 1 to $2^{63}-1$ (that is, from 1 to 9,223,372,036,854,775,807). BIGSERIAL has storage and processing advantages over SERIAL8. |
| SMALLINT              | Stores a 2-byte integer value. These values can be in the range from $-(2^{15}-1)$ to $2^{15}-1$ (that is, from -32,767 to 32,767).   |

## DECIMAL(*p,s*) Data Types

The *p* parameter specifies the *precision* (the total number of digits) and the second parameter, (*s*), specifies the *scale* (the number of digits in the fractional part). If you provide only one parameter, an ANSI-compliant database interprets it as the precision of a fixed-point number and the default scale is 0. If you specify no parameters, and the database is ANSI-compliant, then by default the precision is 16 and the scale is 0.

If the database is not ANSI-compliant, and you specify fewer than 2 parameters, you declare a floating-point DECIMAL, which is not an exact number data type. (See instead the section [Approximate Numeric Data Types on page 1179](#).)

DECIMAL(*p, s*) values are stored internally with the first byte representing a sign bit and a 7-bit exponent in excess-65 format. The other bytes express the mantissa as base-100 digits. This implies that DECIMAL(32, *s*) data types store only *s*-1 decimal digits to the right of the decimal point, if *s* is an odd number.

## Serial Data Types

You can declare columns of SERIAL, BIGSERIAL, or SERIAL8 data types. If user-defined routines require whole-number values for variables, arguments, or returned data types, specify INT, BIGINT, or INT8 as the data types, rather than SERIAL, BIGSERIAL, or SERIAL8. These data types are integer data types that differ primarily in their names, their range, and their storage requirements. Columns of serial data types cannot store values less than 1. A table can have no more than one

SERIAL column and no more than one BIGSERIAL or SERIAL8 column. Because the serial values are assigned by the database server, you cannot use the UPDATE statement to change an existing serial value in the database.

To insert an explicit value into a SERIAL, BIGSERIAL, or SERIAL8 column, specify any integer greater than zero. For details of an alternative way to generate integer values, see [CREATE SEQUENCE statement on page 326](#).

A SERIAL, BIGSERIAL, or SERIAL8 column is unique only if you set a unique index on the column. (The index can also be in the form of a primary key or a unique constraint.) With a unique index, values in serial data type columns are guaranteed to be unique, but successive values are not necessarily contiguous.

## Approximate Numeric Data Types

An *approximate numeric* data type represents numeric values approximately.

Approximate Numeric Data Type

### DECIMAL DEC NUMERIC

<sup>552</sup>(16)

(*precision*)

### FLOAT DOUBLE PRECISION

(*float\_precision*)

<sup>552</sup>SMALLFLOAT

### REAL

| Element                | Description   | Restrictions   | Syntax                                      |
|------------------------|---|--|---|
| <i>float_precision</i> | The <i>float_precision</i> is ignored, but is ANSI/ISO compliant. | Must be a positive integer. Specified value has no effect. | <a href="#">Literal Number on page 1419</a> |
| <i>precision</i>       | Significant digits. Default is 16.                                | An integer; 1 <i>precision</i> 32                          | <a href="#">Literal Number on page 1419</a> |

Use approximate numeric data types for very large and very small numbers that can tolerate some degree of rounding during arithmetic operations.

The following table summarizes the built-in approximate numeric data types.

| Data Type           | Description   |
|---------------------|---|
| DEC( <i>p</i> )     | Synonym for DECIMAL( <i>p</i> )   |
| DECIMAL( <i>p</i> ) | Stores floating-point decimal values in the approximate range from 1.0E-130 to 9.99E+126<br><br>The <i>p</i> parameter specifies the precision. If no precision is specified, the default is 16. This floating-point data type is available as an approximate numeric type only in a database that is not ANSI-compliant. In an ANSI-compliant database, DECIMAL( <i>p</i> ) is implemented as a fixed-point DECIMAL; see <a href="#">Exact Numeric Data Types on page 1176</a> . |

552. Informix® extension

| Data Type           | Description  |
|---------------------|--|
| DOUBLE PRECISION    | ANSI-compliant synonym for FLOAT. The <i>float_precision</i> term is not valid when you use this synonym in data type declarations.  |
| FLOAT               | Stores double-precision floating-point numbers with up to 16 significant digits. The <i>float_precision</i> parameter is accepted in data-type declarations for compliance with the ANSI/ISO standard for SQL, but this parameter has no effect on the actual precision of values that the database server stores. |
| NUMERIC( <i>p</i> ) | ANSI-compliant synonym for DECIMAL( <i>p</i> ) In an ANSI-compliant database, this is implemented as an exact numeric type, with the specified precision and a scale of zero, rather than an approximate numeric (floating-point) data type.   |
| REAL                | ANSI-compliant synonym for SMALLFLOAT  |
| SMALLFLOAT          | Stores single-precision floating-point numbers with approximately 8 significant digits   |

The built-in number data types of Informix® database servers support real numbers. They cannot directly store imaginary or complex numbers.

In Informix®, you must create a user-defined data type for applications that support values that can have an imaginary part.

No more than nine arguments to an external UDR can be DECIMAL data types of SQL that the UDR declares as BigDecimal data types of the Java™ language.

## Large-Object Data Types

Large-object data types can store extremely large column values, such as images and documents, independently of the column.

Large-Object Data Type

**TEXT BYTE**

**IN**

**TABLE** *blobSPACE*

**BLOB CLOB**

| Element          | Description                   | Restrictions | Syntax                                  |
|------------------|-------------------------------|--------------|---|
| <i>blobSPACE</i> | Name of an existing blobSPACE | Must exist   | <a href="#">Identifier on page 1456</a> |

The large object data types can be classified in two categories:

- Simple large objects: TEXT and BYTE
- Smart large objects: CLOB and BLOB

**Related reference**[Storage options on page 376](#)

## Simple-large-object data types

A simple large object data type stores text or binary data in blobspaces.

These are the simple-large-object data types:

**TEXT**

Stores text data of up to  $2^{31}$  bytes

**BYTE**

Stores any digitized data of up to  $2^{31}$  bytes

Do not supply a BYTE value where TEXT is expected. No built-in cast supports BYTE to TEXT data type conversion.

Because of the maximum row size limit of 32,767 bytes, you cannot create a table with more than approximately 195 BYTE or TEXT columns. (This restriction also applies to all varying-length data types and ROW data types.)

For more information about the simple large object data types, see the *Informix® Guide to SQL: Reference*.

For information on how to create blobspaces, see your *Informix® Administrator's Guide*.

## Storing BYTE and TEXT Data

A simple-large-object data type can store text or binary data in blobspaces or in tables. The database server can access a BYTE or TEXT value in one piece. When you specify a BYTE or TEXT data type, you can specify the location in which it is stored. You can store data with the table or in a separate blobspace.

If you are creating a named ROW data type that has a BYTE or TEXT field, you cannot use the IN clause to specify a separate storage space.

The following example shows how blobspaces and dbspaces are specified. The user creates the **resume** table. The data values are stored in the **employ** dbspace. The data in the **vita** column is stored with the table, but the data associated with the **photo** column is stored in a blobspace named **photo\_space**.

```
CREATE TABLE resume
(
  fname          CHAR(15),
  lname         CHAR(15),
  phone         CHAR(18),
  recd_date     DATETIME YEAR TO HOUR,
  contact_date  DATETIME YEAR TO HOUR,
  comments      VARCHAR(250, 100),
  vita         TEXT IN TABLE,
  photo        BYTE IN photo_space
```

```
)  
IN employ;
```

## Smart-large-object data types

A smart large object data type stores text or binary data in sbspaces.

The database server can provide random access to a smart large object value. That is, it can access any portion of the smart large object value. These data types are recoverable. The following list summarizes the smart large object data types that HCL Informix® supports.

### **BLOB**

Stores binary data of up to 4 terabytes ( $4 \times 2^{40}$  bytes)

### **CLOB**

Stores text data of up to 4 terabytes ( $4 \times 2^{40}$  bytes)

A smart large object is stored in a single sbspaces. The SBSPACENAME configuration parameter specifies the system default sbspaces in which smart large objects are created, unless you specify another storage area. For information about how the CREATE TABLE statement can specify nondefault storage locations and nondefault storage characteristics for BLOB or CLOB columns, see the description of the [PUT Clause on page 378](#).

Both of these are built-in opaque data types. Like most opaque types, they cannot be accessed in a database of a non-local database server by a distributed query or by other DML operations, nor can they be returned from a database of another database server by a UDR. For information on accessing BLOB or CLOB values in other databases of the local server, however, see [BOOLEAN and other built-in opaque data types on page 1164](#).

Smart large object data types are not parallelizable. The PDQ feature of Dynamic Serve has no effect on operations that load or unload BLOB or CLOB values, or that process them in queries or in other DML operations.

For more information about the smart large object data types, see the *Informix® Guide to SQL: Reference*.

For information about how to create sbspaces, see your *Informix® Administrator's Guide*.

For information about the built-in functions that you can use to import, export, and copy smart large objects, see [Smart-Large-Object Functions on page 1298](#) and the *Informix® Guide to SQL: Tutorial*.

---

## Time Data Types

The time data types store calendar dates, points in time, and intervals of time.

## Time Data Types

**DATE****INTERVAL**INTERVAL Field Qualifier<sup>554</sup><sup>553</sup>**DATETIME**DATETIME Field Qualifier<sup>555</sup>

The following table summarizes the built-in time data types.

**Data Type****Description****DATE**

Stores a date value as a Julian date in the range from January 1 of the year 1 up to December 31, 9999.

**DATETIME**

Stores a point-in-time date (*year, month, day*) and time-of-day (*hour, minute, second, and fraction of second*), in the range of years 1 to 9999. Also supports contiguous subsets of these time units.

**INTERVAL**

Stores spans of time, in *years* and/or *months*, or in smaller time units (*days, hours, minutes, seconds, and/ or fractions of second*), with up to 9 digits of precision in the largest time unit, if this is not FRACTION. Also supports contiguous subsets of these time units.

For the order of precedence among the Informix® environment variables that can specify the display and data entry format of the built-in time data types, see the topic [Precedence of DATE and DATETIME format specifications on page 1416](#).

## User-Defined Data Type

A user-defined data type is one that a user defines for the database server. Informix® supports two categories of user-defined data types, namely *distinct data types* and *opaque data types*. This is the declaration syntax for user-defined data types:

User-Defined Data Type

Owner Name<sup>556</sup>

.

*opaque\_type distinct\_type*

553. Informix® extension

554. See [INTERVAL Field Qualifier on page 1410](#)

555. See [DATETIME Field Qualifier on page 1191](#)

556. See [Owner name on page 1488](#)

| Element              | Description   | Restrictions   | Syntax                                  |
|----------------------|---|--|---|
| <i>distinct_type</i> | Distinct data type with same structure as an existing data type | Must be unique among data type names in the database | <a href="#">Identifier on page 1456</a> |
| <i>opaque_type</i>   | Name of the opaque data type                                    | Must be unique among data type names in the database | <a href="#">Identifier on page 1456</a> |

In this document, *user-defined data type* is usually abbreviated as UDT.

## Distinct Data Types

A DISTINCT data type is a user-defined data type that is based on one of the following data types:

- a built-in type (including built-in opaque types)
- a user-defined opaque type
- a named ROW type
- an existing DISTINCT type.

The base type of a DISTINCT type cannot be any of the following data types:

- an unnamed ROW type
- a LIST, MULTISSET, SET, or generic COLLECTION type.

The DISTINCT type inherits the length and the alignment of its base type in storage. Informix® automatically creates explicit casts between the DISTINCT type and its base type. To create a DISTINCT type, you must use the CREATE DISTINCT TYPE statement. (For more information, see [CREATE DISTINCT TYPE statement on page 210](#).)

## DISTINCT Types in Distributed Operations

Cross-server and cross-database operations can return DISTINCT types whose base types are built-in atomic data types, if the DISTINCT values are explicitly cast to a built-in data type. The base-type hierarchy and the casts must be identically defined in every participating database.

### Restrictions on base types and on casts

Only a subset of built-in opaque types, however, can be the base type of a DISTINCT value that a distributed query returns. Complex DISTINCT types defined on a ROW base type can be returned only from the local database.

DISTINCT column values cannot be retrieved from another database of the same Informix® instance by a distributed query (nor modified by INSERT, DELETE, MERGE, or UPDATE cross-database distributed operations), nor by a function call, unless all of the following conditions are true:

- The DISTINCT type is defined on one of the following base types:
  - an non-opaque built-in atomic data type
  - a BOOLEAN, BSON, JSON, or LVARCHAR data type
  - a DISTINCT type defined on BOOLEAN, on BSON, on JSON, on LVARCHAR, or on a non-opaque built-in data type.

(This condition also applies recursively to DISTINCT types of DISTINCT types, where the ultimate base type is BOOLEAN, BSON, JSON, or LVARCHAR, or a non-opaque built-in data type.)

- the DISTINCT type is explicitly cast to BOOLEAN, to BSON, to JSON, to LVARCHAR, or to a non-opaque built-in type
- the DISTINCT type, its type hierarchy, and its explicit cast to a built-in type are defined exactly the same way in all participating databases.

For DISTINCT data types in distributed operations, the data type hierarchy must have one of the following forms, which cannot vary across the participating databases:

### Base-type hierarchy for Distributed DISTINCT Types

**DISTINCT OF**

*distinct\_type***DISTINCT OF**

**BOOLEAN BSON JSON**

**LVARCHAR**

**(2048 )**

*(max )*

*built-in\_non-opaque\_type*

| Element                         | Description  | Restrictions  | Syntax                                 |
|---------------------------------|--|---|--|
| <i>built-in_non-opaque_type</i> | Atomic built-in data type that is not opaque           | Type cannot be complex, serial, BYTE, or TEXT   | <a href="#">Data Type on page 1163</a> |
| <i>distinct_type</i>            | DISTINCT type whose base type is another DISTINCT type | Root of this hierarchy must be a BSON, BOOLEAN, JSON, LVARCHAR, or an atomic <i>built-in non-opaque</i> data type | <a href="#">Data Type on page 1163</a> |

#### Important:

The diagram above shows the generalized logical hierarchy of the base types for any DISTINCT data type. Using the DISTINCT OF keywords recursively, however, as in the diagram above, is not valid SQL syntax. The CREATE DISTINCT TYPE statement must specify exactly one base type for the new DISTINCT type. To create a hierarchy of DISTINCT data types, you must issue a separate CREATE DISTINCT TYPE statement for every DISTINCT type in the

hierarchy. For the SQL syntax to define a new DISTINCT data type, see the topic [CREATE DISTINCT TYPE statement on page 210](#).

A user-defined routine can return to the local database a DISTINCT data type from another database of the same Informix® instance only if all of the conditions listed above are true, and the UDR is defined in all of the participating databases.

### The built-in DISTINCT type IDSSECURITYLABEL

The IDSSECURITYLABEL data type, which stores the security label in rows of protected tables, is a built-in DISTINCT type that satisfies this requirement, because its base type is the built-in VARCHAR(128) data type.

In queries that access a protected table in an Informix® database, the security label stored in the IDSSECURITYLABEL column prevents protected rows from being returned by the query, unless the user issuing the query holds sufficient LBAC credentials for the security policy of which that label is a component.

### DISTINCT types in cross-server operations

The same rules that apply to DISTINCT data types in distributed operations across databases of the same Informix® instance also apply to DISTINCT data types in cross-server distributed operations on databases of different Informix® instances.

For additional information about the data types that Informix® supports in distributed operations, see [Data Types in Distributed Queries on page 779](#).

## Opaque Data Types

An opaque data type is a user-defined data type that can be used in the same way as a built-in data type. To create an opaque type, you must use the CREATE OPAQUE TYPE statement. Because an opaque type is encapsulated, you create support functions to access the individual components of an opaque type. The internal storage details of the type are hidden or opaque.

For more information about how to create an opaque data type and its support functions, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

Because of the maximum row size limit of 32,767 bytes, when you create a new table, no more than approximately 195 columns can be varying-length opaque or distinct user-defined data types. (The same restriction applies to BYTE, TEXT, VARCHAR, LVARCHAR, NVARCHAR, and ROW type columns. See [ROW Data Types on page 1187](#) for additional information about ROW data types.)

## Complex Data Type

*Complex data types* are ROW types or COLLECTION types that you create from built-in types, opaque types, distinct types, or other complex types.

Complex Data Type

Row Data Types<sup>557</sup>

Collection Data Types<sup>558</sup>

A single complex data type can include multiple components. When you create a complex type, you define the components of the complex type. Unlike an opaque type, however, a complex type is not encapsulated. You can use SQL to access the individual components of a complex data type. The individual components of a complex data type are called *elements*.

Informix® supports the following categories of complex data types:

- ROW data types: Named ROW types and unnamed ROW types
- COLLECTION data types: SET, MULTISET, and LIST

The elements of a COLLECTION data type must all be of the same data type. You can use the keyword COLLECTION in SPL data type declarations to specify an untyped collection variable. NULL values are not supported in elements of COLLECTION data types.

The elements of a ROW data type can be of different data types, but the pattern of data types from the first to the last element cannot vary for a given ROW data type. NULL values are supported in elements of ROW data types, unless you specify otherwise in the data type declaration or in a constraint.

## ROW Data Types

A ROW data type is a complex data type that can store multiple data values within its ordered set of one or more fields. Informix supports two categories of ROW data types: *named ROW types* that the CREATE ROW TYPE statement registers in the system catalog, and *unnamed ROW types* that ROW constructor expressions define.

You can use this syntax when you assign a ROW data type to a column or to an SPL variable.

Named and unnamed ROW data types

Named ROW data type Unnamed ROW data type

Named ROW data type

*owner.*

*row\_type*

Unnamed ROW data type

**ROW**

```
(
, fielddata_type
)
```

557. See [CREATE ROW TYPE statement on page 307](#)

558. See [Collection Data Types on page 1189](#)

| Element          | Description  | Restrictions   | Syntax   |
|------------------|--|--|--|
| <i>data_type</i> | Data type of <i>field</i>                              | Any built-in type except BYTE or TEXT, or a UDT that has a support function for bit-hashing                          | <a href="#">Data Type on page 1163</a>   |
| <i>field</i>     | Name of a field within <i>row_type</i>                 | Must be unique among field names of the same ROW type  | <a href="#">Identifier on page 1456</a>  |
| <i>owner</i>     | Authorization identifier of the owner of this ROW type | In an ANSI-compliant database, the combination <i>owner.row_type</i> must be unique among data types in the database | <a href="#">Owner name on page 1488</a>  |
| <i>row_type</i>  | Named ROW type that CREATE ROW TYPE statement defined  | ROW type must exist in the database  | <a href="#">Identifier on page 1456</a> ; <a href="#">Data Type on page 1163</a> |

### Named ROW types

You can assign a named ROW type to a table, to a column, or to an SPL variable. A named ROW type must already exist in the database before you can use it in any of the following contexts:

- to create a typed table
- to define a column
- to define an SPL variable of a named ROW type.

A field in a named ROW type can be another existing named ROW type, as in this example:

```
CREATE ROW TYPE row_t ( w INT, y INT);
CREATE ROW TYPE rowspace_t ( u INT, v row_t, z DATE);
```

Each row of the named ROW type `rowspace_t` can store three INT values and one DATE value, but two of those INT values are in the field of ROW type `row_t`.

To specify a named ROW data type in an ANSI-compliant database, you must qualify the *row\_type* with its *owner* name, if you are not the owner of *row\_type*.

A named ROW type can be the child of a supertype within a data type hierarchy, from which it inherits the field data types of its parent ROW type, or it can have no parent supertype. For the DDL syntax to create a new named ROW data type, see [CREATE ROW TYPE statement on page 307](#).

### Unnamed ROW types

An unnamed ROW data type is identified by its structure, which specifies fields that you create with its ROW constructor. For the syntax of unnamed ROW constructors, see [Constructor Expressions on page 1247](#).

You can define a column or an SPL variable as an unnamed ROW data type.

If you omit the field list of the ROW constructor when the DEFINE statement of SPL declares an SPL variable as an unnamed ROW data type, the new variable has a generic ROW data type, to which the SPL routine can assign the field values of

any ROW data type. For the syntax to declare SPL variables as ROW data types, see [Subset of Complex Data Types on page 1096](#).

## Restrictions on ROW types

Columns in database tables cannot be generic ROW types.

An SPL variable declared as a generic ROW data type cannot return the result of an SQL routine. Before you can use a ROW type variable in an SPL routine, you must initialize the row variable with a LET statement or with a SELECT INTO statement.

Fields in a ROW data type cannot include TEXT or BYTE data types. Fields in ROW types also cannot be user-defined types (UDTs) that are not bit-hashable using the built-in hashing function of the database server.

Because of the maximum row size limit of 32,767 bytes, a single table cannot be created with more than approximately 195 ROW type columns.

## Collection Data Types

This diagram shows the syntax to define a column or an SPL variable as a collection data type. (A table can include no more than 97 columns of collection data types.) For the syntax to specify values of collection elements, see [Collection Constructors on page 1248](#).

Collection Data Type

### COLLECTION

#### SET MULTISSET LIST

```
(
  data_type
  (
    data_type
  )
  NOT NULL
  NOT NULL)
```

| Element          | Description   | Restrictions   | Syntax                                 |
|------------------|---|--|--|
| <i>data_type</i> | Data type of each of the elements of the collection | Can be any data type except BIGSERIAL, BYTE, SERIAL, or SERIAL8, or TEXT | <a href="#">Data Type on page 1163</a> |

A SET is an unordered collection of elements, each of which has a unique value. Define a column as a SET data type when you want to store collections whose elements contain no duplicate values and have no associated order.

A MULTISSET is an unordered collection of elements that can have duplicate values. You can define a column as a MULTISSET collection type when you want to store collections whose elements might not be unique and have no specific order associated with them.

A LIST is an ordered collection of elements that can include duplicate elements. A LIST differs from a MULTISET in that each element in a LIST collection has an ordinal position in the collection. You can define a column as a LIST collection type when you want to store collections whose elements might not be unique but have a specific order associated with them.

The keyword COLLECTION can be used in SPL data type declarations to specify an untyped collection variable.

If you attempt to insert a collection that includes one or more duplicate values into a SET column, Informix® issues no error, but the duplicate values are ignored, and only the unique values are inserted.

## Duplicate Elements in DML Operations on SET Columns

The SET data type does not allow duplicate element values in the same collection. If you attempt to insert duplicate elements into a SET data type, or to update a SET column or variable to a value that includes duplicate elements, the database server issues no error or warning when the INSERT or UPDATE statement executes, but only one of the duplicate elements is stored in the SET column or variable.

For example, suppose you create table **t3** with column **a** of the SET data type, and then you insert four rows, some of which include elements that have identical values:

```
> CREATE TABLE t3(a SET(INT NOT NULL));

Table created.

> INSERT INTO t3 VALUES( SET{10, 20, 30} );

1 row(s) inserted.

> INSERT INTO t3 VALUES( SET{10, 20, 10});

1 row(s) inserted.

> INSERT INTO t3 VALUES( SET{10, 10, 10});

1 row(s) inserted.

> INSERT INTO t3 VALUES( SET{10,10,10});

1 row(s) inserted.
```

When you look at the data values that were inserted into column **t3.a**, the four inserted rows include no duplicate element values:

```
> SELECT * FROM t3;

a SET{10      ,20      ,30      }
a SET{10      ,20      }
a SET{10      }
a SET{10      }

4 row(s) retrieved.
```

In this example, Informix® silently discarded all but one instance of the duplicated elements from what the VALUES clause of the INSERT statement specified for each SET value.

Similar behavior occurs if the SET clause of the UPDATE statement includes duplicate elements within the same SET value. Declare collection columns of the MULTISET data type, rather than of the SET data type, if you want the database to store unordered sets that can include duplicate elements within the same collection

## Defining the Element Type

The element type can be any data type except TEXT, BYTE, SERIAL, SERIAL8, or BIGSERIAL. You can nest collection types, using elements of a collection type.

Every element must be of the same type. For example, if the element type of a collection data type is INTEGER, every element must be of type INTEGER.

An exception to this restriction occurs if the database server determines that some elements of a collection of character strings are VARCHAR data types (whose length is limited to 255 or fewer bytes) but other elements are longer than 255 bytes. In this case, the collection constructor can assign a CHAR(*n*) data type to all elements, for *n* the length in bytes of the longest element. If this is undesirable, you can cast the collection to LVARCHAR, to prevent padding extra length in elements of the collection, as in this example:

```
LIST {'first character string longer than 255 bytes . . . ',
      'second character string longer than 255 bytes . . . ',
      'another character string'} ::LIST (LVARCHAR NOT NULL)
```

See [Collection Constructors on page 1248](#) for additional information.

If the element type of a collection is an unnamed ROW type, the unnamed ROW type cannot contain fields that hold unnamed ROW types. That is, a collection cannot contain nested unnamed ROW data types.

The elements of a collection cannot be NULL. When you define a column as a collection data type, you must use the NOT NULL keywords to specify that the elements of the collection cannot be NULL.

Privileges on a collection data type are those of the database column. You cannot specify privileges on individual elements of a collection.

---

## DATETIME Field Qualifier

Use a DATETIME Field Qualifier to specify the largest and smallest unit of time in a DATETIME column or value. Use this segment whenever you see a reference to a DATETIME Field Qualifier in a syntax diagram.

**Syntax**

DATETIME Field Qualifier

**YEAR****TO YEAR TO MONTH TO DAY TO HOUR TO MINUTE TO SECOND****TO FRACTION***(scale)***MONTH****TO MONTH TO DAY TO HOUR TO MINUTE TO SECOND****TO FRACTION***(scale)*

)

**DAY****TO DAY TO HOUR TO MINUTE TO SECOND****TO FRACTION***(scale)***HOUR****TO HOUR TO MINUTE TO SECOND****TO FRACTION***(scale)***MINUTE****TO MINUTE TO SECOND****TO FRACTION***(scale)***SECOND****TO SECOND****TO FRACTION***(scale)***FRACTION****TO FRACTION***(scale)*

| Element      | Description                         | Restrictions               | Syntax                                      |
|--------------|-------------------------------------|----------------------------|---|
| <i>scale</i> | Fraction of a second. Default is 3. | Integer (1 <i>scale</i> 5) | <a href="#">Literal Number on page 1419</a> |

**Usage**

This segment specifies the precision and scale of a DATETIME data type.

Specify, as the first keyword, the largest time unit that the DATETIME column will store. After the keyword TO, specify the smallest unit as the last keyword. These can be the same keyword. If they are different, the qualifier implies that any intermediate time units between the first and last are also recorded by the DATETIME data type.

The keywords can specify the following time units for the DATETIME column.

**Unit of Time****Description****YEAR**

Specifies a year, in the range from A.D. 1 to 9999

**MONTH**

Specifies a month, in the range from 1 (January) to 12 (December)

**DAY**

Specifies a day, in the range from 1 to 28, 29, 30, or 31 (depending on the specific month)

**HOUR**

Specifies an hour, in the range from 0 (midnight) to 23

**MINUTE**

Specifies a minute, in the range from 0 to 59

**SECOND**

Specifies a second, in the range from 0 to 59

**FRACTION**

Specifies a fraction of a second, with up to five decimal places

The default scale is three digits (thousandth of a second).

Unlike INTERVAL qualifiers, DATETIME qualifiers cannot specify nondefault precision (except for FRACTION, when FRACTION is the smallest unit in the qualifier). Some examples of DATETIME qualifiers follow:

|                    |                |
|--------------------|----------------|
| YEAR TO MINUTE     | MONTH TO MONTH |
| DAY TO FRACTION(4) | MONTH TO DAY   |

On some platforms, the system clock cannot support precision greater than FRACTION(3).

An error results if the first keyword represents a smaller time unit than the last, or if you use the plural form of a keyword (such as MINUTES).

Operations on DATETIME values that do not include YEAR in their qualifier use values from the system clock-calendar to supply any additional precision. If the first term in the qualifier is DAY, and the current month has fewer than 31 days, unexpected results can occur.

**Expression**

Data values in SQL statements must be represented as expressions. An *expression* is a specification, which can include operators, operands, and parentheses, that the database server can evaluate to one or more values, or to a reference to some database object.

Expressions can refer to values already in a table of the database, or to values derived from such data, but some expressions (such as TODAY, USER, or literal values) can return values that are independent of the database. You can use expressions to specify values in data-manipulation statements, to define fragmentation strategies, and in other contexts. Use the Expression segment whenever you see a reference to an expression in a syntax diagram.

In most contexts, however, you are restricted to expressions whose returned value is of some specific data type, or of a data type that can be converted by the database server to some required data type.

Informix® database servers support the following categories of expressions:

SQL Expressions

Binary Operators

- +

Cast Expressions <sup>560</sup>

Column Expressions <sup>561</sup>

Conditional Expressions <sup>562</sup>

Constant Expressions <sup>563</sup>

Constructor Expressions <sup>564</sup>

Function Expressions <sup>565</sup>

Statement-Local Variable Expressions <sup>566</sup>

Aggregate Expressions <sup>567</sup>

**NULL** *variable*

<sup>559</sup> *SPL\_variable*

( Expression )

Binary Operators

+ - \* / ||

| Element             | Description  | Restrictions   | Syntax                                  |
|---------------------|--|--|---|
| <i>SPL_variable</i> | In an SPL routine, a variable that contains some expression type that the syntax diagram shows | Must conform to the rules for expressions of that type | <a href="#">Identifier on page 1456</a> |
| <i>variable</i>     | Host or program variable that contains some expression type that the syntax diagram shows      | Must conform to the rules for expressions of that type | Language-specific rules for names       |

## Usage

The following table lists the types of SQL expressions and describes what each type returns.

**Table 18. SQL expressions**

| Expression Type                      | Description  |
|--------------------------------------|--|
| Aggregate functions                  | Returns values from built-in or from user-defined aggregates                                       |
| Arithmetic operators                 | Supports arithmetic operations on one (unary operators) or two (binary operators) numeric operands |
| Concatenation operator               | Concatenates two string values   |
| Cast operators                       | Explicit casts from one data type to another   |
| Column expressions                   | Column values  |
| Conditional expressions              | Returns values that depend on conditional tests  |
| Constant expressions                 | Literal values in data manipulation (DML) statements   |
| Constructor expressions              | Dynamically creates values for complex data types  |
| Function expressions                 | Returns values from built-in or user-defined functions   |
| Statement-Local Variable expressions | References a statement-local variable (SLV) in the same SQL statement where it was declared        |

You can also use host variables or SPL variables as expressions.

## List of Expressions

Each category of SQL expression includes many individual expressions.

The following table lists all the SQL expressions (and some operators) in alphabetical order. The columns in this table have the following meanings:

- **Name** gives the name of each expression.
- **Description** gives a short description of each expression.
- **Syntax** lists the page that shows the syntax of the expression.
- **Usage** shows the page that describes the usage of the expression.

| <b>Name</b>             | <b>Description</b>  | <b>Syntax</b>  | <b>Usage</b>                                      |
|-------------------------|---|--|---|
| ABS function            | Returns absolute value of a numeric argument                              | <a href="#">Algebraic Functions on page 1254</a>           | <a href="#">ABS Function on page 1256</a>         |
| ACOS function           | Returns the arc cosine of a numeric argument                              | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">ACOS Function on page 1323</a>        |
| ACOSH function          | Returns the hyperbolic tangent of the specified numeric input             | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">ACOSH Function on page 1323</a>       |
| ADD_MONTHS function     | Adds a specified number of months   | <a href="#">Time Functions on page 1304</a>                | <a href="#">ADD_MONTHS Function on page 1306</a>  |
| Addition ( + ) operator | Returns the sum of two numeric operands                                   | <a href="#">Expression on page 1193</a>                    | <a href="#">Arithmetic Operators on page 1210</a> |
| ASCII function          | Returns the ASCII codepoint of the first character in its string argument | <a href="#">String-Manipulation Functions on page 1326</a> | <a href="#">ASCII Function on page 1333</a>       |
| ASIN function           | Returns the arc sine of a numeric argument                                | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">ASIN Function on page 1324</a>        |
| ASINH function          | Returns the arc hyperbolic sine of the specified numeric input            | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">ASINH Function on page 1324</a>       |
| ATAN function           | Returns the arc tangent of numeric argument                               | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">ATAN Function on page 1324</a>        |
| ATAN2 function          | Calculates the angular component of polar coordinate arguments            | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">ATAN2 Function on page 1324</a>       |
| ATANH function          | Returns the hyperbolic tangent of the specified numeric input             | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">ATANH Function on page 1324</a>       |
| AVG function            | Returns the mean of a set of numeric values                               | <a href="#">Aggregate Expressions on page 1367</a>         | <a href="#">AVG Function on page 1371</a>         |
| BITAND                  | Returns the bitwise AND of two arguments                                  | <a href="#">Bitwise Logical Functions on page 1211</a>     | <a href="#">BITAND Function on page 1212</a>      |
| BITANDNOT               | Returns the bitwise ANDNOT of two arguments                               | <a href="#">Bitwise Logical Functions on page 1211</a>     | <a href="#">BITANDNOT Function on page 1214</a>   |
| BITNOT                  | Returns the bitwise NOT of two arguments                                  | <a href="#">Bitwise Logical Functions on page 1211</a>     | <a href="#">BITNOT Function on page 1215</a>      |
| BITOR                   | Returns the bitwise OR of two arguments                                   | <a href="#">Bitwise Logical Functions on page 1211</a>     | <a href="#">BITOR Function on page 1213</a>       |

| Name                          | Description  | Syntax   | Usage   |
|-------------------------------|--|--|---|
| BITXOR                        | Returns the bitwise XOR of two arguments   | <a href="#">Bitwise Logical Functions on page 1211</a>     | <a href="#">BITXOR Function on page 1213</a>        |
| CARDINALITY function          | Returns the number of elements in a collection data type (SET, MULTISSET, or LIST)   | <a href="#">CARDINALITY Function on page 1269</a>          | <a href="#">CARDINALITY Function on page 1269</a>   |
| CASE expression               | Returns a value that depends on which of several conditional tests evaluates to true | <a href="#">CASE Expressions on page 1227</a>              | <a href="#">CASE Expressions on page 1227</a>       |
| CAST expression               | Converts an expression to a specified data type                                      | <a href="#">CAST Expressions on page 1217</a>              | <a href="#">CAST Expressions on page 1217</a>       |
| Cast ( :: ) operator          | See "Double-colon ( :: ) cast operator"  | <a href="#">CAST Expressions on page 1217</a>              | <a href="#">CAST Expressions on page 1217</a>       |
| CEIL function                 | Returns the smallest integer that is greater than or equal to its single argument    | <a href="#">Algebraic Functions on page 1254</a>           | <a href="#">CEIL Function on page 1256</a>          |
| CHARACTER_LENGTH function     | See CHAR_LENGTH function. (In multibyte locales, this replaces the LENGTH function.) | <a href="#">Length functions on page 1293</a>              | <a href="#">CHAR_LENGTH Function on page 1294</a>   |
| CHAR_LENGTH function          | Returns count of logical characters in a string argument                             | <a href="#">Length functions on page 1293</a>              | <a href="#">CHAR_LENGTH Function on page 1294</a>   |
| CHARINDEX function            | Returns the location of a substring within a string                                  | <a href="#">CHARINDEX function on page 1347</a>            | <a href="#">CHARINDEX function on page 1347</a>     |
| CHR                           | Returns a code point in the range 0 through 255 from the default code set            | <a href="#">String-Manipulation Functions on page 1326</a> | <a href="#">CHR Function on page 1343</a>           |
| COALESCE function             | Returns the first non-NULL value from a series of expressions                        | <a href="#">COALESCE Function on page 1231</a>             | <a href="#">COALESCE Function on page 1231</a>      |
| Column expression             | Column value from a table  | <a href="#">Column Expressions on page 1219</a>            | <a href="#">Column Expressions on page 1219</a>     |
| CONCAT operator function      | Concatenates the results of two expressions  | <a href="#">String-Manipulation Functions on page 1326</a> | <a href="#">CONCAT Function on page 1327</a>        |
| Concatenation (    ) operator | Concatenates the results of two expressions  | <a href="#">Expression on page 1193</a>                    | <a href="#">Concatenation Operator on page 1215</a> |

| Name                                | Description  | Syntax   | Usage  |
|-------------------------------------|--|--|--|
| Constant expression                 | Expression with a literal, fixed, or variant value   | <a href="#">Constant Expressions on page 1235</a>              | <a href="#">Constant Expressions on page 1235</a>                      |
| COS function                        | Returns the cosine of a radian expression  | <a href="#">Trigonometric Functions on page 1321</a>           | <a href="#">COS Function on page 1322</a>                              |
| COSH function                       | Returns the hyperbolic cosine of the argument, where the argument is an angle expressed in radians | <a href="#">Trigonometric Functions on page 1321</a>           | <a href="#">COSH function on page 1322</a>                             |
| COUNT (as a set of functions)       | Functions that return frequency counts Each form of the COUNT function is listed below.            | <a href="#">Aggregate Expressions on page 1367</a>             | <a href="#">Overview of COUNT Functions on page 1371</a>               |
| COUNT (ALL <i>column</i> ) function | See COUNT ( <i>column</i> ) function.  | <a href="#">Aggregate Expressions on page 1367</a>             | <a href="#">COUNT column Function on page 1373</a>                     |
| COUNT ( <i>column</i> ) function    | Returns the number of non-NULL values in a specified column  | <a href="#">Aggregate Expressions on page 1367</a>             | <a href="#">COUNT column Function on page 1373</a>                     |
| COUNT DISTINCT function             | Returns the number of unique non-NULL values in a specified column                                 | <a href="#">Aggregate Expressions on page 1367</a>             | <a href="#">COUNT DISTINCT and COUNT UNIQUE functions on page 1372</a> |
| COUNT UNIQUE function               | See COUNT DISTINCT function.   | <a href="#">Aggregate Expressions on page 1367</a>             | <a href="#">COUNT DISTINCT and COUNT UNIQUE functions on page 1372</a> |
| COUNT (*) function                  | Returns the cardinality of the set of rows that satisfy a query                                    | <a href="#">Aggregate Expressions on page 1367</a>             | <a href="#">COUNT(*) function on page 1371</a>                         |
| CUME_DIST function                  | Returns percentile rankings for each row in an OLAP partition                                      | <a href="#">OLAP ranking function expressions on page 1388</a> | <a href="#">CUME_DIST function on page 1394</a>                        |
| CURRENT operator                    | Returns the current time as a DATETIME value that consists of the date and the time of day         | <a href="#">Constant Expressions on page 1235</a>              | <a href="#">CURRENT Operator on page 1240</a>                          |
| CURRENT_ROLE operator               | Returns the currently enabled role of the user   | <a href="#">Constant Expressions on page 1235</a>              | <a href="#">CURRENT_ROLE Operator on page 1238</a>                     |
| CURRENT_USER operator               | Returns the authorization identifier of the user. Synonym for USER operator.                       | <a href="#">Constant Expressions on page 1235</a>              | <a href="#">USER or CURRENT_USER Operator on page 1237</a>             |
| <i>sequence</i> .CURRVAL            | Returns the current value of specified <i>sequence</i>   | <a href="#">Constant Expressions on page 1235</a>              | <a href="#">Using CURRVAL on page 1245</a>                             |

| Name  | Description  | Syntax                                       | Usage  |
|---|--|--|--|
| DATE function                               | Converts a nondate argument to a DATE value  | <a href="#">Time Functions on page 1304</a>  | <a href="#">DATE Function on page 1307</a>                               |
| DAY function                                | Returns the day of the month as an integer   | <a href="#">Time Functions on page 1304</a>  | <a href="#">DAY Function on page 1308</a>                                |
| DBINFO ( <i>option</i> )                    | Functions for retrieving database and session information. Each <i>option</i> is listed below. | <a href="#">DBINFO Function on page 1271</a> | <a href="#">DBINFO Options on page 1272</a>                              |
| DBINFO ('bigserial')                        | Returns most recently inserted BIGSERIAL value   | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'serial8' and 'bigserial' options on page 1278</a> |
| DBINFO ('cdrsession')                       | Shows whether a DML operation is part of a replicated transaction                              | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'cdrsession' option on page 1276</a>               |
| DBINFO ('dbhostname')                       | Returns the host name of the database server to which a client application is connected        | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'dbhostname' Option on page 1277</a>               |
| DBINFO ('dbname')                           | Returns the identifier of the database to which a client application is connected              | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'dbname' Option on page 1276</a>                   |
| DBINFO ('dbspace', <i>tblspace_number</i> ) | Returns the name of a dbspace corresponding to a tblspace number                               | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the ('dbspace', tblspace_num) Option on page 1273</a>  |
| DBINFO ('get_tz')                           | Returns the time zone of the current session   | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'get_tz' Option on page 1279</a>                   |
| DBINFO ('serial8')                          | Returns most recently inserted SERIAL8 value   | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'serial8' and 'bigserial' options on page 1278</a> |
| DBINFO ('sessionid')                        | Returns the session ID of the current session  | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'sessionid' Option on page 1275</a>                |
| DBINFO ('sqlca.sqlerrd1')                   | Returns the last serial value inserted in a table  | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'sqlca.sqlerrd1' Option on page 1274</a>           |
| DBINFO ('sqlca.sqlerrd2')                   | Returns the number of rows processed by DML statements, and by EXECUTE PROCEDURE               | <a href="#">DBINFO Function on page 1271</a> | <a href="#">Using the 'sqlca.sqlerrd2' Option on page 1274</a>           |

| Name   | Description   | Syntax   | Usage  |
|--|---|--|--|
|  | and EXECUTE FUNCTION statements   |  |  |
| DBINFO ('utc_current')                         | Returns the current Coordinated Universal Time (UTC) value.   | <a href="#">DBINFO Function on page 1271</a>                     | Using the 'utc_current' Option on page 1279                |
| DBINFO ('utc_to_datetime', <i>expression</i> ) | Returns the DATETIME value of an integer or column <i>expression</i> that specifies a UTC value.  | <a href="#">DBINFO Function on page 1271</a>                     | Using the 'utc_to_datetime' Option on page 1280            |
| DBINFO ('version', <i>parameter</i> )          | Returns all or part, as specified by the <i>parameter</i> , of the exact version of the database server to which the client application is connected. | <a href="#">DBINFO Function on page 1271</a>                     | Using the 'version' Option on page 1277                    |
| DBSERVERNAME function                          | Returns the name of the database server   | <a href="#">Constant Expressions on page 1235</a>                | DBSERVERNAME and SITENAME Operators on page 1239           |
| DECODE function                                | Evaluates one or more expression pairs and compares the <i>when</i> expression in each pair with a specified value expression                         | <a href="#">DECODE Function on page 1233</a>                     | <a href="#">DECODE Function on page 1233</a>               |
| DECRYPT_BINARY function                        | Returns a plain-text BLOB data value after processing an encrypted BLOB argument  | <a href="#">Encryption and decryption functions on page 1281</a> | <a href="#">DECRYPT_BINARY Function on page 1287</a>       |
| DECRYPT_CHAR function                          | Returns a plain-text string or CLOB after processing an encrypted argument  | <a href="#">Encryption and decryption functions on page 1281</a> | <a href="#">DECRYPT_CHAR Function on page 1287</a>         |
| DEFAULT_ROLE operator                          | Returns the default role of the current user  | <a href="#">Constant Expressions on page 1235</a>                | <a href="#">DEFAULT_ROLE Operator on page 1238</a>         |
| DEGREES function                               | Converts units of radians to degrees  | <a href="#">Trigonometric Functions on page 1321</a>             | <a href="#">DEGREES function on page 1325</a>              |
| DELETING Boolean operator                      | Returns 't' if triggering event is a DELETE   | <a href="#">Trigger-Type Boolean Operator on page 1153</a>       | <a href="#">Trigger-Type Boolean Operator on page 1153</a> |
| DENSERANK function                             | Synonym for the DENSE_RANK function   | <a href="#">OLAP ranking function expressions on page 1388</a>   | <a href="#">DENSE_RANK function on page 1392</a>           |

| <b>Name</b>                             | <b>Description</b>  | <b>Syntax</b>  | <b>Usage</b>   |
|---|---|--|--|
| DENSE_RANK function                     | Ranks each row in an OLAP partition, with no gaps in ranks                                  | <a href="#">OLAP ranking function expressions on page 1388</a>     | <a href="#">DENSE_RANK function on page 1392</a>                 |
| Division (/) operator                   | Returns the quotient of two numeric operands  | <a href="#">Expression on page 1193</a>                            | <a href="#">Arithmetic Operators on page 1210</a>                |
| Double-colon (::) cast operator         | Converts the value of an expression to a specified data type                                | <a href="#">CAST Expressions on page 1217</a>                      | <a href="#">CAST Expressions on page 1217</a>                    |
| Double-pipe (  ) concatenation operator | Returns a string that joins one string operand to another string operand                    | <a href="#">Expression on page 1193</a>                            | <a href="#">Concatenation Operator on page 1215</a>              |
| ENCRYPT_AES function                    | Returns an encrypted string or BLOB after processing a plain-text string, BLOB, or CLOB     | <a href="#">Encryption and decryption functions on page 1281</a>   | <a href="#">ENCRYPT_AES Function on page 1288</a>                |
| ENCRYPT_TDES function                   | Returns an encrypted string or BLOB after processing a plain-text string, BLOB, or CLOB     | <a href="#">Encryption and decryption functions on page 1281</a>   | <a href="#">ENCRYPT_TDES Function on page 1289</a>               |
| EXP function                            | Returns the exponent of a numeric expression  | <a href="#">Exponential and Logarithmic Functions on page 1290</a> | <a href="#">EXP Function on page 1291</a>                        |
| EXTEND function                         | Resets precision of DATETIME or DATE value  | <a href="#">Time Functions on page 1304</a>                        | <a href="#">EXTEND Function on page 1313</a>                     |
| FILETOBLOB function                     | Creates a BLOB value from data stored in a specified operating-system file                  | <a href="#">Smart-Large-Object Functions on page 1298</a>          | <a href="#">FILETOBLOB and FILETOCLOB Functions on page 1299</a> |
| FILETOCLOB function                     | Creates a CLOB value from data stored in a specified operating-system file                  | <a href="#">Smart-Large-Object Functions on page 1298</a>          | <a href="#">FILETOBLOB and FILETOCLOB Functions on page 1299</a> |
| FIRST_VALUE function                    | Returns the value of a specified expression for the first row in each OLAP window partition | <a href="#">OLAP aggregation function expressions on page 1396</a> | <a href="#">LAST_VALUE function on page 1398</a>                 |
| FLOOR function                          | Returns the largest integer that is smaller than or equal to its single argument            | <a href="#">Algebraic Functions on page 1254</a>                   | <a href="#">FLOOR Function on page 1257</a>                      |
| FORMAT_UNITS function                   | Returns a character string that specifies a number and                                      | <a href="#">FORMAT_UNITS Function on page 1358</a>                 | <a href="#">FORMAT_UNITS Function on page 1358</a>               |

| Name                       | Description   | Syntax   | Usage  |
|----------------------------|---|--|--|
|                            | abbreviated units of memory or of storage   |  |  |
| GETHINT function           | Returns a plain-text hint string after processing an encrypted data-string argument                       | <a href="#">Encryption and decryption functions on page 1281</a>   | <a href="#">GETHINT Function on page 1290</a>              |
| GREATEST function          | Returns the maximum value in a set of values  | <a href="#">Algebraic Functions on page 1254</a>                   | <a href="#">GREATEST function on page 1257</a>             |
| HEX function               | Returns the hexadecimal encoding of a base-10 integer argument  | <a href="#">HEX Function on page 1292</a>                          | <a href="#">HEX Function on page 1292</a>                  |
| Host variable              | See Variable.   | <a href="#">Expression on page 1193</a>                            | <a href="#">Expression on page 1193</a>                    |
| IFX_ALLOW_NEWLINE function | Sets a newline session mode that allows or disallows newline characters in quoted strings                 | <a href="#">IFX_ALLOW_NEWLINE Function on page 1361</a>            | <a href="#">IFX_ALLOW_NEWLINE Function on page 1361</a>    |
| INITCAP function           | Converts a string argument to a string in which only the initial letter of each word is uppercase         | <a href="#">Case-Conversion Functions on page 1343</a>             | <a href="#">INITCAP Function on page 1345</a>              |
| INSERTING Boolean operator | Returns 't' if triggering event is an INSERT  | <a href="#">Trigger-Type Boolean Operator on page 1153</a>         | <a href="#">Trigger-Type Boolean Operator on page 1153</a> |
| INSTR function             | Returns position of Nth occurrence of a substring within a string   | <a href="#">INSTR function on page 1349</a>                        | <a href="#">INSTR function on page 1349</a>                |
| LAG function               | Returns an expression value for the row at a specified offset before the current row in an OLAP partition | <a href="#">OLAP ranking function expressions on page 1388</a>     | <a href="#">LAG and LEAD functions on page 1389</a>        |
| LAST_DAY function          | Returns the date of the last day of the month that its argument specifies                                 | <a href="#">Time Functions on page 1304</a>                        | <a href="#">LAST_DAY Function on page 1310</a>             |
| LAST_VALUE function        | Returns the value of a specified expression for the last row in an OLAP window partition                  | <a href="#">OLAP aggregation function expressions on page 1396</a> | <a href="#">LAST_VALUE function on page 1398</a>           |
| LEAD function              | Returns an expression value for the row at a specified offset   | <a href="#">OLAP ranking function expressions on page 1388</a>     | <a href="#">LAG and LEAD functions on page 1389</a>        |

| Name                        | Description  | Syntax   | Usage  |
|-----------------------------|--|--|--|
|                             | after the current row in an OLAP partition   |  |  |
| LEAST function              | Returns the minimum value in a set of values   | <a href="#">Algebraic Functions on page 1254</a>                   | <a href="#">LEAST function on page 1258</a>          |
| LEFT function               | Returns the leftmost N characters of a string  | <a href="#">LEFT function on page 1351</a>                         | <a href="#">LEFT function on page 1351</a>           |
| LEN function                | Synonym for the LENGTH function  | <a href="#">Length functions on page 1293</a>                      | <a href="#">LENGTH Function on page 1293</a>         |
| LENGTH function             | Returns the number of bytes in a character column, not including trailing blank spaces | <a href="#">Length functions on page 1293</a>                      | <a href="#">LENGTH Function on page 1293</a>         |
| LIST collection constructor | Constructor for ordered collections that can contain duplicate values                  | <a href="#">Collection Constructors on page 1248</a>               | <a href="#">Collection Constructors on page 1248</a> |
| Literal BOOLEAN             | Literal representation of a BOOLEAN value  | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Constant Expressions on page 1235</a>    |
| Literal collection          | Represents elements in a collection data type  | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Literal Collection on page 1246</a>      |
| Literal DATETIME            | Represents a DATETIME value  | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Literal DATETIME on page 1242</a>        |
| Literal INTERVAL            | Represents an INTERVAL value   | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Literal INTERVAL on page 1243</a>        |
| Literal number              | Represents a numeric value   | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Literal Number on page 1237</a>          |
| Literal opaque type         | Represents an opaque data type   | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Constant Expressions on page 1235</a>    |
| Literal row                 | Represents the elements in a ROW data type   | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Literal Row on page 1246</a>             |
| LN                          | Returns the natural logarithm of a numeric argument                                    | <a href="#">Exponential and Logarithmic Functions on page 1290</a> | <a href="#">LN function on page 1291</a>             |
| LOCOPY function             | Creates a copy of a smart large object   | <a href="#">Smart-Large-Object Functions on page 1298</a>          | <a href="#">LOCOPY Function on page 1303</a>         |
| LOG10 function              | Returns the base-10 logarithm of a numeric argument                                    | <a href="#">Exponential and Logarithmic Functions on page 1290</a> | <a href="#">LOG10 Function on page 1291</a>          |

| Name                            | Description   | Syntax   | Usage  |
|---------------------------------|---|--|--|
| LOGN function                   | Returns the natural logarithm of a numeric argument                                   | <a href="#">Exponential and Logarithmic Functions on page 1290</a> | <a href="#">LOGN Function on page 1291</a>           |
| LOTOFILE function               | Copies a BLOB or CLOB object to a file  | <a href="#">Smart-Large-Object Functions on page 1298</a>          | <a href="#">LOTOFILE Function on page 1301</a>       |
| LOWER function                  | Converts uppercase letters to lowercase   | <a href="#">Case-Conversion Functions on page 1343</a>             | <a href="#">LOWER Function on page 1345</a>          |
| LPAD function                   | Returns a string that is left-padded by a specified number of pad characters          | <a href="#">String-Manipulation Functions on page 1326</a>         | <a href="#">LPAD Function on page 1340</a>           |
| LTRIM function                  | Removes specified leading pad characters from a string.                               | <a href="#">String-Manipulation Functions on page 1326</a>         | <a href="#">LTRIM Function on page 1336</a>          |
| MAX function                    | Returns the largest in a specified set of values                                      | <a href="#">Aggregate Expressions on page 1367</a>                 | <a href="#">MAX Function on page 1376</a>            |
| MDY function                    | Returns a DATE value from integer arguments   | <a href="#">Time Functions on page 1304</a>                        | <a href="#">MDY Function on page 1313</a>            |
| MIN function                    | Returns the smallest in a specified set of values                                     | <a href="#">Aggregate Expressions on page 1367</a>                 | <a href="#">MIN Function on page 1376</a>            |
| MOD function                    | Returns the modulus (the integer-division remainder value) from two numeric arguments | <a href="#">Algebraic Functions on page 1254</a>                   | <a href="#">MOD Function on page 1258</a>            |
| MONTH function                  | Returns the month value from a DATE or DATETIME argument                              | <a href="#">Time Functions on page 1304</a>                        | <a href="#">MONTH Function on page 1308</a>          |
| MONTHS_BETWEEN function         | Returns the difference in months between two time arguments                           | <a href="#">Time Functions on page 1304</a>                        | <a href="#">MONTHS_BETWEEN Function on page 1309</a> |
| Multiplication ( * ) operator   | Returns the product of two numeric operands   | <a href="#">Expression on page 1193</a>                            | <a href="#">Arithmetic Operators on page 1210</a>    |
| MULTISET collection constructor | Constructor for a non-ordered collection of elements that can contain duplicate value | <a href="#">Collection Constructors on page 1248</a>               | <a href="#">Collection Constructors on page 1248</a> |
| NEXT_DAY function               | Returns the earliest calendar date that satisfies both of two conditions              | <a href="#">Time Functions on page 1304</a>                        | <a href="#">NEXT_DAY Function on page 1311</a>       |
| <i>sequence</i> .NEXTVAL        | Increments value of the specified <i>sequence</i>                                     | <a href="#">Constant Expressions on page 1235</a>                  | <a href="#">Using NEXTVAL on page 1245</a>           |

| Name                      | Description   | Syntax   | Usage   |
|---------------------------|---|--|---|
| NTILE function            | Classifies the rows in an OLAP partition into N ranked categories, called <i>tiles</i> , of similar cardinalities | <a href="#">OLAP ranking function expressions on page 1388</a> | <a href="#">NTILE function on page 1395</a>         |
| NULL keyword              | Unknown, missing, or logically undefined value  | <a href="#">NULL Keyword on page 1250</a>                      | <a href="#">NULL Keyword on page 1250</a>           |
| NULLIF function           | Returns NULL if both arguments are equal  | <a href="#">NULLIF Function on page 1232</a>                   | <a href="#">NULLIF Function on page 1232</a>        |
| NVL function              | Returns the value of a not-NULL argument, or a specified value if the argument is NULL                            | <a href="#">NVL Function on page 1232</a>                      | <a href="#">NVL Function on page 1232</a>           |
| NVL2 function             | Returns the second argument when the first argument is not NULL   | <a href="#">NVL2 Function on page 1292</a>                     | <a href="#">NVL2 Function on page 1292</a>          |
| OCTET_LENGTH function     | Returns the number of bytes in a character column, including any trailing blank spaces                            | <a href="#">Length functions on page 1293</a>                  | <a href="#">OCTET_LENGTH Function on page 1294</a>  |
| PERCENT_RANK function     | Returns a ranking value for each row in an OLAP window partition, normalized to a range from 0 to 1               | <a href="#">OLAP ranking function expressions on page 1388</a> | <a href="#">PERCENT_RANK function on page 1393</a>  |
| POW function              | Raises a base value to a specified power  | <a href="#">Algebraic Functions on page 1254</a>               | <a href="#">POW Function on page 1259</a>           |
| Power® function           | Synonym for POW function  | <a href="#">Algebraic Functions on page 1254</a>               | <a href="#">POW Function on page 1259</a>           |
| Procedure-call expression | See user-defined function.  | <a href="#">User-Defined Functions on page 1362</a>            | <a href="#">User-Defined Functions on page 1362</a> |
| Program variable          | See variable.   | <a href="#">Expression on page 1193</a>                        | <a href="#">Expression on page 1193</a>             |
| QUARTER function          | Returns the calendar quarter of a DATE or DATETIME value  | <a href="#">Time Functions on page 1304</a>                    | <a href="#">QUARTER Function on page 1308</a>       |
| Quoted string             | Literal character string  | <a href="#">Constant Expressions on page 1235</a>              | <a href="#">Quoted String on page 1237</a>          |
| RADIANS function          | Converts units of degrees to radians  | <a href="#">Trigonometric Functions on page 1321</a>           | <a href="#">RADIANS function on page 1325</a>       |

| <b>Name</b>              | <b>Description</b>   | <b>Syntax</b>  | <b>Usage</b>  |
|--------------------------|--|--|---|
| RANGE function           | Returns the range of a specified set of values   | <a href="#">Aggregate Expressions on page 1367</a>                 | <a href="#">RANGE Function on page 1377</a>                     |
| RANK                     | Returns an ordinal number to rank each row in an OLAP window   | <a href="#">OLAP ranking function expressions on page 1388</a>     | <a href="#">RANK function on page 1392</a>                      |
| RATIOTOREPORT function   | Synonym for the RATIO_TO_REPORT function   | <a href="#">OLAP aggregation function expressions on page 1396</a> | <a href="#">RATIO_TO_REPORT function on page 1399</a>           |
| RATIO_TO_REPORT function | Returns the fractional ratio of each row value to the sum for all rows in the same OLAP window partition | <a href="#">OLAP aggregation function expressions on page 1396</a> | <a href="#">RATIO_TO_REPORT function on page 1399</a>           |
| REPLACE function         | Replaces specified characters in a source string   | <a href="#">String-Manipulation Functions on page 1326</a>         | <a href="#">REPLACE Function on page 1340</a>                   |
| REVERSE                  | Reverses the order of characters in a source string  | <a href="#">String-Manipulation Functions on page 1326</a>         | <a href="#">REVERSE function on page 1339</a>                   |
| RIGHT function           | Returns the N rightmost characters from a source string  | <a href="#">RIGHT function on page 1351</a>                        | <a href="#">RIGHT function on page 1351</a>                     |
| ROOT function            | Returns a real, positive, Nth root value of a numeric argument   | <a href="#">Algebraic Functions on page 1254</a>                   | <a href="#">ROOT Function on page 1259</a>                      |
| ROUND function           | Returns the rounded value of an argument   | <a href="#">Algebraic Functions on page 1254</a>                   | <a href="#">ROUND Function on page 1260</a>                     |
| ROW constructor          | Constructor for a named ROW data type  | <a href="#">Constructor Expressions on page 1247</a>               | <a href="#">ROW constructors on page 1247</a>                   |
| ROWNUMBER function       | Synonym for the ROW_NUMBER function  | <a href="#">OLAP numbering function expression on page 1386</a>    | <a href="#">OLAP numbering function expression on page 1386</a> |
| ROW_NUMBER function      | Returns sequential integers for each row in an OLAP window partition                                     | <a href="#">OLAP numbering function expression on page 1386</a>    | <a href="#">OLAP numbering function expression on page 1386</a> |
| RPAD function            | Returns a string right-padded by a specified number of pad characters                                    | <a href="#">String-Manipulation Functions on page 1326</a>         | <a href="#">RPAD Function on page 1341</a>                      |
| RTRIM function           | Removes trailing blank pad characters from a string  | <a href="#">String-Manipulation Functions on page 1326</a>         | <a href="#">RTRIM Function on page 1337</a>                     |

| Name                       | Description  | Syntax  | Usage   |
|----------------------------|--|---|---|
| SECLABEL_BY_COMP function  | Returns the security label whose components are the arguments                      | <a href="#">Security Label Support Functions on page 1294</a>     | <a href="#">SECLABEL_BY_COMP Function on page 1296</a>            |
| SECLABEL_BY_NAME function  | Returns the security label whose identifier is the argument                        | <a href="#">Security Label Support Functions on page 1294</a>     | <a href="#">SECLABEL_BY_NAME Function on page 1296</a>            |
| SECLABEL_TO_CHAR function  | Returns the security label whose string format is the argument                     | <a href="#">Security Label Support Functions on page 1294</a>     | <a href="#">SECLABEL_TO_CHAR Function on page 1297</a>            |
| SELECTING Boolean operator | Returns 't' if triggering event is a SELECT  | <a href="#">Trigger-Type Boolean Operator on page 1153</a>        | <a href="#">Trigger-Type Boolean Operator on page 1153</a>        |
| SET collection constructor | Constructor for an unordered collection of unique elements                         | <a href="#">Collection Constructors on page 1248</a>              | <a href="#">Collection Constructors on page 1248</a>              |
| SIGN function              | Returns an indicator of the sign of the numeric argument                           | <a href="#">SIGN function on page 1298</a>                        | <a href="#">SIGN function on page 1298</a>                        |
| SIN function               | Returns the sine of a radians argument   | <a href="#">Trigonometric Functions on page 1321</a>              | <a href="#">SIN Function on page 1322</a>                         |
| SINH function              | Returns the hyperbolic sine of a radians argument                                  | <a href="#">Trigonometric Functions on page 1321</a>              | <a href="#">SINH function on page 1322</a>                        |
| SITENAME function          | See DBSERVERNAME function.   | <a href="#">Constant Expressions on page 1235</a>                 | <a href="#">DBSERVERNAME and SITENAME Operators on page 1239</a>  |
| SLV expression             | A statement-local variable (SLV) whose scope is the SQL statement that declares it | <a href="#">Statement-Local Variable Declaration on page 1364</a> | <a href="#">Statement-Local Variable Expressions on page 1365</a> |
| SPACE function             | Returns a string of N blank characters   | <a href="#">String-Manipulation Functions on page 1326</a>        | <a href="#">SPACE function on page 1338</a>                       |
| SPL routine expression     | See "User-defined functions"   | <a href="#">User-Defined Functions on page 1362</a>               | <a href="#">User-Defined Functions on page 1362</a>               |
| SPL variable               | SPL variable that stores an expression   | <a href="#">Expression on page 1193</a>                           | <a href="#">Expression on page 1193</a>                           |
| SQLCODE function           | Returns <b>sqlca.sqlcode</b> value to an SPL UDR                                   | <a href="#">SQLCODE Function (SPL) on page 1270</a>               | <a href="#">SQLCODE Function (SPL) on page 1270</a>               |
| SQRT function              | Returns the square root of a numeric argument                                      | <a href="#">Algebraic Functions on page 1254</a>                  | <a href="#">SQRT Function on page 1259</a>                        |
| STDEV function             | Returns the standard deviation of a data set                                       | <a href="#">Aggregate Expressions on page 1367</a>                | <a href="#">STDEV Function on page 1378</a>                       |

| <b>Name</b>                 | <b>Description</b>  | <b>Syntax</b>  | <b>Usage</b>  |
|-----------------------------|---|--|---|
| SUBSTR function             | Returns a substring of a source string                              | <a href="#">SUBSTR function on page 1352</a>               | <a href="#">SUBSTR function on page 1352</a>              |
| SUBSTRB function            | Returns a substring of a source string                              | <a href="#">SUBSTRB function on page 1354</a>              | <a href="#">SUBSTRB function on page 1354</a>             |
| SUBSTRING function          | Returns a substring of a source string                              | <a href="#">SUBSTRING function on page 1355</a>            | <a href="#">SUBSTRING function on page 1355</a>           |
| SUBSTRING_INDEX function    | Returns a substring that includes the Nth occurrence of a delimiter | <a href="#">SUBSTRING_INDEX function on page 1357</a>      | <a href="#">SUBSTRING_INDEX function on page 1357</a>     |
| Substring ([x, y]) operator | Returns a substring from a string operand                           | <a href="#">Column Expressions on page 1219</a>            | <a href="#">Using the Substring Operator on page 1225</a> |
| Subtraction (-) operator    | Returns the difference between two numbers                          | <a href="#">Expression on page 1193</a>                    | <a href="#">Arithmetic Operators on page 1210</a>         |
| SUM function                | Returns the sum of a specified set of values                        | <a href="#">Aggregate Expressions on page 1367</a>         | <a href="#">SUM Function on page 1377</a>                 |
| SYSDATE operator            | Returns the current DATETIME value from the system clock.           | <a href="#">Constant Expressions on page 1235</a>          | <a href="#">SYSDATE Operator on page 1241</a>             |
| TAN function                | Returns the tangent of a radians expression                         | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">TAN Function on page 1323</a>                 |
| TANH function               | Returns the hyperbolic tangent of a radians argument                | <a href="#">Trigonometric Functions on page 1321</a>       | <a href="#">TANH Function on page 1323</a>                |
| TO_CHAR function            | Converts a time or number to a character string                     | <a href="#">Time Functions on page 1304</a>                | <a href="#">TO_CHAR Function on page 1314</a>             |
| TO_DATE function            | Converts a character string to a DATETIME value                     | <a href="#">Time Functions on page 1304</a>                | <a href="#">TO_DATE Function on page 1319</a>             |
| TO_NUMBER function          | Converts a number or a character string to a DECIMAL value          | <a href="#">TO_NUMBER Function on page 1320</a>            | <a href="#">TO_NUMBER Function on page 1320</a>           |
| TODAY operator              | Returns the current system date                                     | <a href="#">Constant Expressions on page 1235</a>          | <a href="#">TODAY Operator on page 1240</a>               |
| TRIM function               | Drops blank pad characters from a character string argument         | <a href="#">String-Manipulation Functions on page 1326</a> | <a href="#">TRIM Function on page 1334</a>                |
| TRUNC function              | Returns a truncated numeric or time value                           | <a href="#">Algebraic Functions on page 1254</a>           | <a href="#">TRUNC Function on page 1265</a>               |

| <b>Name</b>                | <b>Description</b>   | <b>Syntax</b>  | <b>Usage</b>   |
|----------------------------|--|--|--|
| Unary minus ( - ) sign     | Specifies a negative ( < 0 ) numeric value                         | <a href="#">Expression on page 1193</a>                    | <a href="#">Arithmetic Operators on page 1210</a>            |
| Unary plus ( + ) sign      | Specifies a positive ( > 0 ) numeric value .                       | <a href="#">Expression on page 1193</a>                    | <a href="#">Arithmetic Operators on page 1210</a>            |
| UNITS operator             | Convert an integer to an INTERVAL value                            | <a href="#">Constant Expressions on page 1235</a>          | <a href="#">UNITS Operator on page 1243</a>                  |
| UPDATING Boolean operator  | Returns 't' if triggering event is an UPDATE                       | <a href="#">Trigger-Type Boolean Operator on page 1153</a> | <a href="#">Trigger-Type Boolean Operator on page 1153</a>   |
| UPPER function             | Converts lowercase letters to uppercase                            | <a href="#">Case-Conversion Functions on page 1343</a>     | <a href="#">UPPER Function on page 1345</a>                  |
| User-defined aggregate     | Aggregate that a user defines (as opposed to a built-in aggregate) | <a href="#">User-Defined Aggregates on page 1380</a>       | <a href="#">User-Defined Aggregates on page 1380</a>         |
| User-defined function      | Function that a user writes (as opposed to a built-in function)    | <a href="#">User-Defined Functions on page 1362</a>        | <a href="#">User-Defined Functions on page 1362</a>          |
| USER operator              | Returns the authorization identifier of the current user           | <a href="#">Constant Expressions on page 1235</a>          | <a href="#">USER or CURRENT_USER Operator on page 1237</a>   |
| Variable                   | Host or program variable that stores a value                       | <a href="#">Expression on page 1193</a>                    | <a href="#">Expression on page 1193</a>                      |
| VARIANCE function          | Returns the variance for a set of numeric values                   | <a href="#">Aggregate Expressions on page 1367</a>         | <a href="#">VARIANCE Function on page 1378</a>               |
| WEEKDAY function           | Returns an integer code for the day of the week                    | <a href="#">Time Functions on page 1304</a>                | <a href="#">WEEKDAY Function on page 1309</a>                |
| Window aggregate functions | Return aggregate results from OLAP window partitions               | <a href="#">OLAP window expressions on page 1383</a>       | <a href="#">OLAP window aggregate functions on page 1400</a> |
| YEAR function              | Returns a 4-digit integer representing a year                      | <a href="#">Time Functions on page 1304</a>                | <a href="#">YEAR Function on page 1309</a>                   |
| * symbol                   | See "Multiplication ( * ) operator"                                | <a href="#">Expression on page 1193</a>                    | <a href="#">Arithmetic Operators on page 1210</a>            |

Sections that follow describe the syntax and usage of each expression that appears in the preceding table.

## Arithmetic Operators

Binary arithmetic operators can combine expressions that return numbers.

| Arithmetic Operation | Arithmetic Operator | Operator Function | Arithmetic Operation | Arithmetic Operator | Operator Function |
|----------------------|---------------------|-------------------|----------------------|---------------------|-------------------|
| Addition             | +                   | <b>plus()</b>     | Multiplication       | *                   | <b>times()</b>    |
| Subtraction          | -                   | <b>minus()</b>    | Division             | /                   | <b>divide()</b>   |

The following examples use binary arithmetic operators:

```
quantity * total_price
price * 2
COUNT(*) + 2
```

If you combine a DATETIME value with one or more INTERVAL values, all the fields of the INTERVAL value must be present in the DATETIME value; no implicit EXTEND function is performed. In addition, you cannot use YEAR to MONTH intervals with DAY to SECOND intervals. For additional information about binary arithmetic operators, see the *Informix® Guide to SQL: Reference*.

The binary arithmetic operators have associated operator functions, as the preceding table shows. Connecting two expressions with a binary operator is equivalent to invoking the associated operator function on the expressions. For example, the following two statements both select the product of the **total\_price** column and 2. In the first statement, the \* operator implicitly invokes the **times()** function.

```
SELECT (total_price * 2) FROM items
WHERE order_num = 1001;
SELECT times(total_price, 2) FROM items
WHERE order_num = 1001;
```

You cannot use arithmetic operators to combine expressions that use aggregate functions with column expressions.

The database server provides the operator functions associated with the relational operators for all built-in data types. You can define new versions of these operator functions to handle your own user-defined data types.

For more information, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

The database server also supports the following unary arithmetic operators.

| Sign of Number | Unary Arithmetic Operator | Operator Function  |
|----------------|---------------------------|--------------------|
| Positive       | +                         | <b>positive( )</b> |
| Negative       | -                         | <b>negate( )</b>   |

The unary arithmetic operators have the associated operator functions that the preceding table shows. You can define new versions of these functions to handle your own user-defined data types. For more information on this topic, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

If any value that participates in an arithmetic expression is NULL, the value of the entire expression is NULL, as the following example shows:

```
SELECT order_num, ship_charge/ship_weight FROM orders
WHERE order_num = 1023;
```

If either **ship\_charge** or **ship\_weight** is NULL, the value returned for the expression **ship\_charge/ship\_weight** is also NULL. If the NULL expression **ship\_charge/ship\_weight** is used in a condition, its truth value cannot be TRUE, and the condition is not satisfied (unless the NULL expression is an operand of the **IS NULL** operator).

## Bitwise Logical Functions

Use the bitwise logical functions to perform named bit operations.

Bitwise Logical Functions

568

### **BITAND BITOR BITXOR BITANDNOT**

*(int8\_expr,int8\_expr)*

**BITNOT***(int8\_expr)*

| Element          | Description  | Restrictions                                       | Syntax                                  |
|------------------|--|--|---|
| <i>int8_expr</i> | Number expression that can be converted to an INT8 value | For <b>BITNOT</b> the maximum size is reduced by 1 | <a href="#">Expression on page 1193</a> |

The arguments to these functions can be any numeric data type that can be converted to the INT8 data type.

Except for **BITNOT**, which takes a single argument, these bitwise logical functions take two arguments that can be converted to an INT8 value.

568. Informix® extension

If both arguments have the same integer types, the data type of the returned value is the same type as the arguments. If the two arguments are of different integer types, the returned value is the integer type with the greater precision. For example, if the first argument is of type INT, and the second argument is of type INT8, the returned value is of type INT8.

If the arguments are any other numeric type, such as DECIMAL, SMALLFLOAT, FLOAT, or MONEY, or some combination of those types, the returned data type is DECIMAL(32).

If using host variables, and the data types of the arguments are not known at prepare time, the data type INTEGER is assumed for both arguments, and the returned value is INTEGER. If, after prepare, at execution time, a different data type value is supplied for the host variable, Informix® issues a -9750 error. To prevent such an occurrence, you can specify the host variable data type by using a cast, as in the following ESQL/C program fragment:

```
sprintf(query1, ,
    bitand( ?::int8, ?::int8) from mytab);
EXEC SQL prepare selectq from :query;
EXEC SQL declare select_cursor cursor for selectq;
EXEC SQL open select_cursor
    using :hostvar_int8_input1, :hostvar_int8_input2;
EXEC SQL fetch select_cursor into :var_int8_output;
```

## BITAND Function

The **BITAND** function takes two arguments. The arguments can be any number type value that can be converted to an INT8 value.

Fractional values are truncated before the bit operation. The result is the AND for the two arguments.

If both arguments have the same integer types, the data type of the returned value is the same type as the arguments. If the arguments are of different integer types (for example, INT and INT8), the data type with the greater precision is returned. If the arguments are any other numeric type, such as DECIMAL, SMALLFLOAT, FLOAT, or MONEY, or some combination of those types, the returned data type is DECIMAL(32).

The following example illustrates a query that calls the **BITAND** function:

```
select task_id, task_status,
    decode(bitand(task_status,1), 1, ' Y', ' N') as task_a,
    decode(bitand(task_status,2), 2, ' Y', ' N') as task_b,
    decode(bitand(task_status,4), 4, ' Y', ' N') as task_c
from tasks;
```

The following table shows the output of this SELECT statement.

| task_id | task_status | task_a | task_b | task_c |
|---------|-------------|--------|--------|--------|
| 100     | 1           | Y      | N      | N      |
| 101     | 1           | Y      | N      | N      |
| 102     | 2           | N      | Y      | N      |
| 103     | 4           | N      | N      | Y      |
| 104     | 6           | N      | Y      | Y      |

| task_id | task_status | task_a | task_b | task_c |
|---------|-------------|--------|--------|--------|
| 105     | 3           | Y      | Y      | N      |
| 106     | 5           | Y      | N      | Y      |
| 107     | 7           | Y      | Y      | Y      |

## BITOR Function

The **BITOR** function takes two arguments. The arguments can be any number type value that can be converted to an INT8 value.

Fractional values are truncated before the bit operation. The result is the bitwise OR of its two arguments.

If both arguments have the same integer types, the data type of the returned value is the same type as the arguments. If the arguments are of different integer types (for example, INT and INT8), the returned type is the type with the greater precision. If the arguments are any other numeric type, such as DECIMAL, SMALLFLOAT, FLOAT, or MONEY, or some combination of those types, the returned data type is DECIMAL(32)

The following example illustrates a query that calls the **BITOR** function:

```
SELECT BITOR(8, 20) AS bitor FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

| bitor |
|-------|
| 28    |

## BITXOR Function

The **BITXOR** function takes two arguments. The arguments can be any number type value that can be converted to an INT8 value.

Fractional values are truncated before the bit operation. The result is the bitwise XOR of its two arguments.

If both arguments have the same integer types, the data type of the returned value is the same type as the arguments. If the arguments are of different integer types (for example, INT and INT8), the returned type is the type with the greater precision. If the arguments are any other numeric type, such as DECIMAL, SMALLFLOAT, FLOAT, or MONEY, or some combination of those types, the returned data type is DECIMAL(32).

The following example illustrates a query that calls the **BITXOR** function:

```
SELECT BITXOR(41, 33) AS bitxor FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

---

| bitxor |
|--------|
| 8      |

---

This query calls the **BITXOR** function with negative arguments:

```
SELECT BITXOR(-20, -41) AS bitxor FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

---

| bitxor |
|--------|
| 59     |

---

## BITANDNOT Function

The **BITANDNOT** function takes two arguments. The arguments can be any number type value that can be converted to an INT8 value.

Fractional values are truncated before the bit operation. The result is the same as `BITAND(arg1, BITNOT(arg2))` for the two arguments.

If both arguments have the same integer types, the data type of the returned value is the same type as the arguments. If the arguments are of different integer types (for example, INT and INT8), the returned type is the type with the greater precision. If the arguments are any other numeric type, such as DECIMAL, SMALLFLOAT, FLOAT, or MONEY, or some combination of those types, the returned data type is DECIMAL(32).

The query in the following example calls the **BITANDNOT** function:

```
SELECT BITANDNOT(20,-20) AS bitandnot FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

---

| bitandnot |
|-----------|
| 16        |

---

The following query calls the equivalent **BITAND** and **BITNOT** functions for the arguments in the previous example:

```
select bitand(20, bitnot(-20)) as bitandnot from systables
where tabid = 1;
```

The following table shows the output of this SELECT statement.

---

| bitandnot |
|-----------|
| 16        |

---

## BITNOT Function

The **BITNOT** function can take any number type value that is one less than the maximum INT8 value.

Fractional values are truncated before the bit operation. The result is the bitwise NOT of its argument.

The returned data type is the same type as the argument if the argument is SMALLINT, INT, BIGINT, or INT8. Otherwise the returned data type is DECIMAL(32).

The following query calls the **BITNOT** function:

```
SELECT BITNOT(8) AS bitnot FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

| bitnot |
|--------|
| -9     |

The next query calls the **BITNOT** function with a negative argument:

```
SELECT BITNOT(-20) AS bitnot FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

| bitnot |
|--------|
| 19     |

## Concatenation Operator

The concatenation operator is a binary operator, whose syntax is shown in the general diagram for an SQL [Expression on page 1193](#). You can use the concatenation operator (||) to concatenate two expressions that evaluate to character data types or to numeric data types. These examples show some possible concatenated expression combinations.

- The first example concatenates the **zipcode** column to the first three letters of the **lname** column.
- The second example concatenates the suffix **.dbg** to the contents of a host variable called **file\_variable**.
- The third example concatenates the value that the **TODAY** operator returns to the string `Date`.

```
lname[1,3] || zipcode
:file_variable || '.dbg'
'Date:' || TODAY
```

You cannot use the concatenation operator in the following embedded-language statements:

- ALLOCATE COLLECTION
- ALLOCATE DESCRIPTOR
- ALLOCATE ROW
- CREATE FUNCTION FROM
- CREATE PROCEDURE FROM
- CREATE ROUTINE FROM
- DEALLOCATE COLLECTION
- DEALLOCATE DESCRIPTOR
- DEALLOCATE ROW DESCRIBE
- DESCRIBE INPUT
- EXECUTE
- FLUSH
- GET DESCRIPTOR
- GET DIAGNOSTICS
- PUT
- SET AUTOFREE
- SET CONNECTION
- SET DESCRIPTOR
- WHENEVER

Except as noted for the DECLARE and PREPARE statement, routines written in external languages, such as the Informix® ESQL/C language, cannot use the concatenation operator in the following dynamic SQL statements:

- CLOSE
- DECLARE
- EXECUTE IMMEDIATE
- FETCH
- FREE
- OPEN
- PREPARE

Although input parameters of the DECLARE statement, such as a *cursor\_id* specification, cannot be expressions that include the concatenation operator, Informix® ESQL/C routines can use this operator in a SELECT, INSERT, EXECUTE FUNCTION, or EXECUTE PROCEDURE statement within the DECLARE statement.

Informix® ESQL/C routines can use the concatenation operator in the text of the SQL statement or statements that you pass to the PREPARE statement.

In SPL routines, you can include the concatenation operator in an expression that specifies the text of the SQL statement that you pass to the EXECUTE IMMEDIATE statement or to the PREPARE statement, even if the calling context of the SPL routine is Informix® ESQL/C routines.

You cannot use the concatenation operator directly with user-defined data types, with complex or large-object data types, nor with operands that are not built-in character or number data types. You must explicitly cast UDTs or other unsupported data types to a built-in character or numeric data type before you can pass the result to the concatenation operator.

The data type of the result of a concatenation operation depends of the data types of the operands and on the length of the resulting string, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The concatenation operator ( `||` ) has an associated operator function called **CONCAT**. The **CONCAT** function cannot be overloaded.

When you define a text-based UDT, you can define a **CONCAT** function to concatenate objects of that user-defined data type. For more information, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

## CAST Expressions

Use the `CAST (... AS ...)` keywords or the double-colon ( `::` ) cast operator to convert the data type of the value of an *expression* to some other *target data type*.

If an SQL statement includes the cast operator or the `CAST (... AS ...)` keywords, the database server examines the **syscasts** system catalog table for an existing cast corresponding to the data types of the *expression* value and the target data types that the Cast Expression specifies. If no built-in cast, explicit cast, or implicit cast registered in the system catalog can perform the specified conversion, the SQL statement returns an error.

Cast Expressions

**CAST**(*expression*

::*target\_type*

**AS***target\_type*)

*expression*

::*target\_type*

| Element            | Description   | Restrictions  | Syntax                                  |
|--------------------|---|---|---|
| <i>expression</i>  | Expression whose data type will be replaced by a <i>target_type</i>                     | Must evaluate to an atomic, or JSON document, or large object, or ROW data type | <a href="#">Expression on page 1193</a> |
| <i>target_type</i> | Data type replacing the type returned by <i>expression</i> (or by an intermediate cast) | See <a href="#">Rules for the Target Data Type on page 1218</a>                 | <a href="#">Data Type on page 1163</a>  |

## Usage

A non-recursive cast expression converts a data value from its current data type directly to a specified target data type.

569. See [Expression on page 1193](#)

To execute an SQL statement that includes the cast operator or the `CAST (... AS ...)` keywords, the database server searches the **syscasts** system catalog table for an existing cast corresponding to

- the data type of the *expression* value in the **syscasts.argument\_type** column,
- and the *target data type* that the Cast Expression specifies in the **syscasts.result\_type** column.

If no built-in cast, explicit cast, or implicit cast registered in the **syscasts** table matches these criteria for performing the specified conversion, the database server returns an error.

In this case, you might consider whether a recursive CAST expression is required, using intermediate data types. You might also consider whether you can use the [CREATE CAST statement on page 198](#) to define and register in the system catalog an appropriate new explicit or implicit cast for data-type conversion to the target type.

For examples of explicit cast expressions for target types of non-opaque, user-defined, and large object data types, see [Examples of Cast Expressions on page 1219](#).

### Recursive CAST expressions

As the syntax diagram indicates, however, the `::target_type` syntax can be used recursively, so that the value of the original source expression is cast to one or more successive intermediate data types before it is cast to the last target type.

For example, the following expression casts a DATETIME (YEAR TO DAY) value to MONEY(16,2), using DATE, INTEGER, and DECIMAL as intermediate data types:

```
CAST (CURRENT::DATE::INTEGER::DECIMAL AS MONEY(16,2))
```

The next CAST expression, without the `CASE` or `AS` keywords, is logically equivalent:

```
CURRENT::DATE::INTEGER::DECIMAL::MONEY(16,2)
```

**Tip:** Use caution before interpreting this syntax example, which was designed to illustrate multiple casts within a single CAST expression, as validation of "Time is money" economic theories.

## Rules for the Target Data Type

The following rules restrict the *target data type* in cast expressions:

- The target data type must be either a built-in type, a user-defined type, or a named row type in the database.
- The target data type cannot be an unnamed row or a collection type.
- The target data type can be a BLOB data type under the following conditions:
  - The source expression (the expression to be cast to another data type) is a BYTE data type.
  - The source expression is a user-defined type and the user has defined a cast from the user-defined type to the BLOB type.
- The target data type can be a CLOB type under these conditions:
  - The source expression is a TEXT data type.
  - The source expression is a user-defined type and the user has defined a cast from the user-defined type to the CLOB type.
- You cannot cast a BLOB data type to a BYTE data type.

- You cannot cast a CLOB data type to a TEXT data type.
- An explicit or implicit cast must exist that can convert the data type of the source expression to the target data type.

## Examples of Cast Expressions

The following examples show two different ways to convert the sum of  $x$  and  $y$  to a user-defined data type, **user\_type**. The two methods produce identical results. Both require the existence of an explicit or implicit cast from the type returned by  $(x + y)$  to the user-defined type:

```
CAST ((x + y) AS user_type)
(x + y)::user_type
```

The following examples show two different ways of finding the integer equivalent of the expression **expr**. Both require the existence of an implicit or explicit cast from the data type of **expr** to the INTEGER data type:

```
CAST (expr AS INTEGER)
expr::INTEGER
```

In the following example, the user casts a BYTE column to the BLOB type and copies the BLOB data to an operating-system file:

```
SELECT LOTOFILE(mybytecol::blob, 'fname', 'client')
FROM mytab
WHERE pkey = 12345;
```

In the following example, the user casts a TEXT column to a CLOB value and then updates a CLOB column in the same table to have the CLOB value derived from the TEXT column:

```
UPDATE newtab SET myclobcol = mytextcol::clob;
```

## The Keyword NULL in Cast Expressions

Cast expressions can appear in the projection list, including expressions of the form `NULL::datatype`, where *datatype* is any data type known to the database:

```
SELECT newtable.col0, null::int FROM newtable;
```

The keyword NULL has a global scope of reference within expressions. In SQL, the keyword NULL is the only syntactic mechanism for accessing a NULL value. Any attempt to redefine or restrict the global scope of the keyword NULL (for example, declaring an SPL variable called **null**) disables any cast expression that involves a NULL value. Make sure that the keyword NULL receives its global scope in all expression contexts.

## Column Expressions

A *column expression* specifies a data value in a column in the database, or a substring of the value, or a field within a ROW-type column, or a field in a BSON column.

## Column Expressions

*table* .*view* .*synonym* .*alias* .*column*

570. Informix® extension

571. Use path no more than three times

572. Use path no more than 32 times

| Element                      | Description   | Restrictions  | Syntax  |
|------------------------------|---|---|---|
|                              |   | ancestor field names must be included.  |   |
| <i>column</i>                | Name of a column  | Restrictions depend on the SQL statement where <i>column</i> occurs   | <a href="#">Identifier on page 1456</a>           |
| <i>first , last</i>          | Integers indicating positions of first and last characters within <i>column</i> | The <i>column</i> must be of type CHAR, VARCHAR, NCHAR, NVARCHAR, BYTE, or TEXT, and 0 < <i>first</i> = <i>last</i>                 | <a href="#">Literal Number on page 1419</a>       |
| <i>row_col_expr</i>          | Expression that returns ROW-type values   | Must return a ROW data type   | <a href="#">Expression on page 1193</a>           |
| <i>row_column</i>            | Name of a ROW-type column   | Must be a named ROW data type or an unnamed ROW data type   | <a href="#">Identifier on page 1456</a>           |
| <i>row_field_name</i>        | Name of a ROW field in the ROW column or ROW-column expression                  | Must be a member of the row that <i>row-column name</i> or <i>row_col_expr</i> or <i>row_field name</i> (for nested rows) specifies | <a href="#">Identifier on page 1456</a>           |
| <i>synonym , table, view</i> | Table, view, or synonym (for the table or view) that contains <i>column</i>     | Synonym and the table or view to which it points must exist   | <a href="#">Database Object Name on page 1450</a> |

You qualify a column name with a table name or alias to distinguish between columns that have the same name but are in different tables. You use dot notation to select a field from a ROW or a BSON column.

The following examples illustrate some formats of column expressions:

- Unqualified column name: `company`
- Column name that is qualified by table name: `items.price`
- Substring of a character-type column: `catalog_advert [1,15]`
- Multilevel BSON field identifier: `bson_col.person.cars.1`

In syntax contexts that support a default value for a column, you can omit the default column expression.

### Example

#### Example: Qualify columns with table names

The following statement, two column expressions qualify the column name, **customer\_num**, with the table names **customer** and **orders**:

```
SELECT * FROM customer, orders
WHERE customer.customer_num = orders.customer_num;
```

**Example****Example: Qualify columns with table aliases**

The following statement includes column expressions that qualify column name, **customer\_num**, with the table aliases **c** and **o**:

```
SELECT * FROM customer c, orders o
WHERE c.customer_num = o.customer_num;
```

**Example****Example: Select a field from a ROW column**

The following statements creates a table with a ROW column that is named **rect** and that has four fields:

```
CREATE TABLE rectangles
(
  area float,
  rect ROW(x int, y int, length float, width float)
);
```

The following statement uses dot notation to access the **length** field of the **rect** column:

```
SELECT rect.length FROM rectangles
WHERE area = 64;
```

**Example****Example: Select a multilevel field from a BSON column**

The following statements create and populate a BSON column that is named **bson\_col**:

```
CREATE DATABASE testdb WITH LOG;
CREATE TABLE IF NOT EXISTS bson_table(bson_col BSON);

INSERT INTO bson_table VALUES(
  '{person:{givenname:"Jim",surname:"Flynn",age:29,cars:["dodge","olds"]}}'
  ::JSON::BSON);
```

Nested in the **person** field is an array that is named **cars**, which has two values. The values in arrays do not have field names. You specify array values with numbers that represent the position in the array, starting with 0 for the first value.

The following statement selects the second value in the **cars** array that is nested in the **person** field:

```
SELECT bson_col.person.cars.1::JSON FROM bson_table;

(expression)
{cars:"olds"}
```

**Related information**

[BSON and JSON built-in opaque data types on page 1165](#)

## Using Dot Notation

Dot notation (sometimes called the *membership operator*) qualifies an SQL identifier with another SQL identifier of which it is a component. You separate the identifiers with the period (.) symbol.

Column projections qualify a column name with the following SQL identifiers:

- Table name: *table\_name.column\_name*
- View name: *view\_name.column\_name*
- Synonym name: *syn\_name.column\_name*

Field projections directly access fields in a ROW or a BSON column: *column\_name.field\_name*. BSON documents can have a hierarchical structure. You can specify multiple fields and positions in arrays, each separated by a period. A field name or array position must be preceded by all its ancestor field names.

## Selecting All Fields of a ROW Column with Asterisk Notation

If you want to select all fields of a column that has a ROW type, you can specify the column name without using dot notation. For example, you can select all fields of the **rect** column as follows:

```
SELECT rect FROM rectangles
WHERE area = 64;
```

You can also use asterisk (\*) notation to project all the fields of a column that has a ROW data type. For example, if you want to use asterisk notation to select all fields of the **rect** column, you can enter the following statement:

```
SELECT rect.* FROM rectangles
WHERE area = 64;
```

Asterisk notation is easier than specifying each field of the **rect** column individually:

```
SELECT rect.x, rect.y, rect.length, rect.width
FROM rectangles
WHERE area = 64;
```

Asterisk notation for ROW fields is valid in the projection list of a SELECT statement. It can specify all fields of a ROW-type column or the data that a ROW-column expression returns.

Asterisk notation is not necessary with ROW-type columns, because you can specify the column name alone to project all of its fields. Asterisk notation is quite helpful, however, with ROW-type expressions such as subqueries and user-defined functions that return ROW-type values. For more information, see [Using Dot Notation with Row-Type Expressions on page 1224](#).

You can use asterisk notation with columns and expressions of ROW data types in the projection list of a SELECT statement only. You cannot use asterisk notation with columns and expressions of ROW type in any other clause of a SELECT statement.

## Selecting Nested Fields

When the ROW type that defines a column itself contains other ROW types, the column contains nested fields. Use dot notation to access these nested fields within a column.

For example, assume that the **address** column of the **employee** table contains the fields: **street**, **city**, **state**, and **zip**. In addition, the **zip** field contains the nested fields: **z\_code** and **z\_suffix**. A query on the **zip** field returns values for the **z\_code** and **z\_suffix** fields. You can specify, however, that a query returns only specific nested fields. The following example shows how to use dot notation to construct a SELECT statement that returns rows for the **z\_code** field of the **address** column only:

```
SELECT address.zip.z_code
FROM employee;
```

## Rules of Precedence

The database server uses the following precedence rules to interpret dot notation:

1. schema *name\_a* . table *name\_b* . column *name\_c* . field *name\_d*
2. table *name\_a* . column *name\_b* . field *name\_c* . field *name\_d*
3. column *name\_a* . field *name\_b* . field *name\_c* . field *name\_d*

When the meaning of an identifier is ambiguous, the database server uses precedence rules to determine which database object the identifier specifies. Consider the following two tables:

```
CREATE TABLE b (c ROW(d INTEGER, e CHAR(2)));
CREATE TABLE c (d INTEGER);
```

In the following SELECT statement, the expression **c.d** references column **d** of table **c** (rather than field **d** of column **c** in table **b**) because a table identifier has a higher precedence than a column identifier:

```
SELECT *
FROM b,c
WHERE c.d = 10;
```

For more information about precedence rules and how to use dot notation with ROW columns, see the *Informix® Guide to SQL: Tutorial*.

## Using Dot Notation with Row-Type Expressions

Besides specifying a column of a ROW data type, you can also use dot notation with any expression that evaluates to a ROW type. In an INSERT statement, for example, you can use dot notation in a subquery that returns a single row of values.

Assume that you created a ROW type named **row\_t**:

```
CREATE ROW TYPE row_t (part_id INT, amt INT);
```

Also assume that you created a typed table named **tab1** that is based on the **row\_t** ROW type:

```
CREATE TABLE tab1 OF TYPE row_t;
```

Assume also that you inserted the following values into table **tab1**:

```
INSERT INTO tab1 VALUES (ROW(1,7));
INSERT INTO tab1 VALUES (ROW(2,10));
```

Finally, assume that you created another table named **tab2**:

```
CREATE TABLE tab2 (colx INT);
```

Now you can use dot notation to insert the value from only the **part\_id** column of table **tab1** into the **tab2** table:

```
INSERT INTO tab2
VALUES ((SELECT t FROM tab1 t
WHERE part_id = 1).part_id);
```

The asterisk form of dot notation is not necessary when you want to select all fields of a ROW-type column because you can specify the column name alone to select all of its fields. The asterisk form of dot notation can be quite helpful, however, when you use a subquery, as in the preceding example, or when you call a user-defined function to return ROW-type values.

Suppose that a user-defined function named **new\_row** returns ROW-type values, and you want to call this function to insert the ROW-type values into a table. Asterisk notation makes it easy to specify that all the ROW-type values that the **new\_row()** function returns are to be inserted into the table:

```
INSERT INTO mytab2 SELECT new_row (mycol).* FROM mytab1;
```

References to the fields of a ROW-type column or a ROW-type expression are not allowed in fragment expressions. A fragment expression is an expression that defines a table fragment or an index fragment in SQL statements like CREATE TABLE, CREATE INDEX, and ALTER FRAGMENT.

## Using the Substring Operator

You can use the substring operator on CHAR, VARCHAR, NCHAR, NVARCHAR, BYTE, and TEXT columns to define a *column substring* as the portion of the column that is specified by the expression.

After the identifier of a character column, when a pair of bracket ( [ ] ) symbols enclose a comma-separated pair of unsigned integers in which the *first* integer is greater than zero but not greater than the *last* integer, Informix® interprets the brackets as the substring operator. The expression returns the *first* through *last* characters of the data value in the column, where *first* and *last* define a substring. For example, in the expression `cat_advert [6,15]`, the returned value is the 6th through 15th characters of column **cat\_advert**.

In the default locale, if the data value occupies at least 15 bytes, this expression evaluates to a substring that includes ten bytes of the column value, but in a multibyte locale this expression returns a string of ten consecutive logical characters whose storage length might exceed 10 bytes, beginning with the sixth logical character. For more information on the GLS aspects of column substrings, see the *Informix® GLS User's Guide*.

In the following example, if a value in the **lname** column of the **customer** table is `Greenburg`, the following expression evaluates to `burg`:

```
lname[6,9]
```

A conditional expression can include a column expression that uses the substring operator ( [ *first*, *last* ] ), as in the following example:

```
SELECT lname FROM customer WHERE phone[5,7] = '356';
```

Here the quotation marks are required, to prevent the database server from applying a numeric filter to the digits in the criterion value.

See also the section [String-Manipulation Functions on page 1326](#), which describes two built-in SQL functions, **SUBSTR()** and **SUBSTRING()** that can specify a substring expression within an SQL statement.

**Note:** The database server can use substrings defined by the substring operator as index filters in queries. This is not the case, however, for substrings defined by **SUBSTR( )** or **SUBSTRING( )**, nor for other built-in string manipulation functions.

## Using Rowids

In Informix®, you can use the **rowid** column that is associated with a table row as a property of the row. The **rowid** column is essentially a hidden column in nonfragmented tables and in fragmented tables that were created with the **WITH ROWIDS** clause. The **rowid** column is unique for each row, but it is not necessarily sequential. It is recommended, however, that you use primary keys as an access method rather than exploiting the **rowid** column.

The following examples use the **ROWID** keyword in a **SELECT** statement:

```
SELECT *, ROWID FROM customer;

SELECT fname, ROWID FROM customer ORDER BY ROWID;

SELECT HEX(rowid) FROM customer WHERE customer_num = 106;
```

The last example shows how to get the page number (the first six digits after 0x) and the slot number (the last two digits) of the location of your row.

You cannot use the **ROWID** keyword in the select list of the Projection clause of a query that contains an aggregate function.

## Using Smart Large Objects

The **SELECT**, **UPDATE**, and **INSERT** statements do not manipulate the values of smart large objects directly. Instead, they use a *handle value*, which is a type of pointer, to access the **BLOB** or **CLOB** value, as follows:

- The **SELECT** statement returns a handle value to the **BLOB** or **CLOB** value that the projection list specifies. **SELECT** does not return the actual data for the **BLOB** or **CLOB** column that the projection list specifies. Instead, it returns a handle value to the column data.
- The **INSERT** and **UPDATE** statements do not send the actual data for the **BLOB** or **CLOB** column to the database server. Instead, they accept a handle value to this data as the value to be inserted or updated.

To access the data of a smart-large-object column, you must use one of the following application programming interfaces (APIs):

- From within Informix® ESQL/C programs, use the Informix® ESQL/C library functions that access smart large objects. For more information, see the *Informix® ESQL/C Programmer's Manual*.
- From within a C program such as a DataBlade® module, use the Client and Server API.

You cannot use the name of a smart-large-object column in expressions that involve arithmetic operators. For example, operations such as addition or subtraction on the smart-large-object handle value have no meaning.

When you select a smart-large-object column, you can assign the handle value to any number of columns: all columns with the same handle value share the CLOB or BLOB value. This storage arrangement reduces the amount of disk space that the CLOB or BLOB value, but when several columns share the same smart-large-object value, the following conditions result:

- The chance of lock contention on a CLOB or BLOB column increases. If two columns share the same smart-large-object value, the data might be locked by either column that needs to access it.
- The CLOB or BLOB value can be updated from a number of points.

To remove these constraints, you can create separate copies of the BLOB or CLOB data for each column that needs to access it. You can use the **LOCOPY** function to create a copy of an existing smart large object.

You can also use the built-in functions **LOTOFILE**, **FILETOCLOB**, and **FILETOBLOB** to access smart-large-object values, as described in [Smart-Large-Object Functions on page 1298](#). For more information on the BLOB and CLOB data types, see the *Informix® Guide to SQL: Reference*.

---

## Conditional Expressions

Conditional expressions return values that depend on the outcome of conditional tests. This diagram shows the syntax for Conditional Expressions.

Conditional Expressions

CASE Expressions <sup>573</sup>

COALESCE Function <sup>578</sup>

NVL Function <sup>574</sup>

NVL2 Function <sup>575</sup>

NULLIF Function <sup>576</sup>

DECODE Function <sup>577</sup>

## CASE Expressions

The CASE expression allows an SQL statement such as the SELECT statement to return one of several possible results, depending on which of several conditions evaluates to true.

The CASE expression has two forms: generic CASE expressions and linear CASE expressions.

573. See [CASE Expressions on page 1227](#)

574. See [NVL Function on page 1232](#)

575. See [NVL2 Function on page 1292](#)

576. See [NULLIF Function on page 1232](#)

577. See [DECODE Function on page 1233](#)

578. See [COALESCE Function on page 1231](#)

CASE Expressions

Generic CASE Expression <sup>579</sup>

Linear CASE Expression <sup>580</sup>

You must include at least one WHEN clause in the CASE expression. Subsequent WHEN clauses and the ELSE clause are optional. You can use a generic or linear CASE expression wherever you can use a column expression in an SQL statement (for example, in the Projection clause a SELECT statement).

Expressions in the search condition or the result value expression can contain subqueries, and you can nest a CASE expression in another CASE expression.

When a CASE expression appears in an aggregate expression, you cannot use aggregate functions in the CASE expression.

You can specify a trigger-type Boolean operator (DELETING, INSERTING, SELECTING, or UPDATING) as a condition in a CASE expression only within a trigger routine.

The following query fragment declares aliases for two aggregate column expressions:

```
SELECT . . .
    SUM(orders.ship_weight) as o2,
    COUNT(DISTINCT
        CASE WHEN orders.backlog MATCHES 'n'
            THEN orders.order_num END ) AS o3,
    . . .
```

Here the argument to **SUM** is a DECIMAL(8,2) column value, and the **COUNT DISTINCT** aggregate takes a **CASE** expression as its argument.

Do not confuse CASE expressions with the CASE statement of SPL, which supports different syntax and functionality.

## CASE expressions data type compatibility

In a CASE expression, all the results should be of the same data type or be compatible data types.

If the results in all the WHEN ... THEN branch clauses are not of the same data type or compatible data types, an error occurs.

The following table shows which character data types are compatible and the data type that is returned for each combination.

**Table 19. Data types returned from compatible character data types**

| Data type     | NCHAR (>255) | NCHAR (<=255) | NVARCHAR | CHAR (<=255) | CHAR (>255) | VARCHAR  | LVARCHAR (>255) | LVARCHAR (<=255) |
|---------------|--------------|---------------|----------|--------------|-------------|----------|-----------------|------------------|
| NCHAR (>255)  | NCHAR        | NCHAR         | NCHAR    | NCHAR        | NCHAR       | NCHAR    | NCHAR           | NCHAR            |
| NCHAR (<=255) | NCHAR        | NCHAR         | NVARCHAR | NCHAR        | NCHAR       | NVARCHAR | NCHAR           | NCHAR            |
| NVARCHAR      | NCHAR        | NVARCHAR      | NVARCHAR | NVARCHAR     | NCHAR       | NVARCHAR | NCHAR           | NVARCHAR         |
| CHAR (<=255)  | NCHAR        | NCHAR         | NVARCHAR | CHAR         | CHAR        | VARCHAR  | CHAR            | CHAR             |

579. See [Generic CASE Expressions on page 1229](#)

580. See [Linear CASE Expressions on page 1230](#)

Table 19. Data types returned from compatible character data types (continued)

| Data type        | NCHAR (>255) | NCHAR (<=255) | NVARCHAR | CHAR (<=255) | CHAR (>255) | VARCHAR | LVARCHAR (>255) | LVARCHAR (<=255) |
|------------------|--------------|---------------|----------|--------------|-------------|---------|-----------------|------------------|
| CHAR (>255)      | NCHAR        | NCHAR         | NCHAR    | CHAR         | CHAR        | CHAR    | CHAR            | CHAR             |
| VARCHAR          | NCHAR        | NVARCHAR      | NVARCHAR | VARCHAR      | CHAR        | VARCHAR | CHAR            | VARCHAR          |
| LVARCHAR (>255)  | NCHAR        | NCHAR         | NCHAR    | CHAR         | CHAR        | CHAR    | LVARCHAR        | LVARCHAR         |
| LVARCHAR (<=255) | NCHAR        | NCHAR         | NVARCHAR | CHAR         | CHAR        | VARCHAR | LVARCHAR        | LVARCHAR         |

The following table shows which numeric data types are compatible and the data type that is returned for each combination.

Table 20. Data types returned from compatible numeric data types

| Data type  | INTEGER | SMALLINT | SERIAL  | DECIMAL | FLOAT   | SMALLFLOAT | MONEY | BIGINT  | BIGSERIAL |
|------------|---------|----------|---------|---------|---------|------------|-------|---------|-----------|
| INTEGER    | INTEGER | INTEGER  | INTEGER | DECIMAL | DECIMAL | DECIMAL    | MONEY | DECIMAL | DECIMAL   |
| SMALLINT   | INTEGER | SMALLINT | INTEGER | DECIMAL | DECIMAL | DECIMAL    | MONEY | DECIMAL | DECIMAL   |
| SERIAL     | INTEGER | INTEGER  | SERIAL  | DECIMAL | DECIMAL | DECIMAL    | MONEY | DECIMAL | DECIMAL   |
| DECIMAL    | DECIMAL | DECIMAL  | DECIMAL | DECIMAL | DECIMAL | DECIMAL    | MONEY | DECIMAL | DECIMAL   |
| FLOAT      | DECIMAL | DECIMAL  | DECIMAL | DECIMAL | FLOAT   | FLOAT      | MONEY | DECIMAL | DECIMAL   |
| SMALLFLOAT | DECIMAL | DECIMAL  | DECIMAL | DECIMAL | FLOAT   | SMALLFLOAT | MONEY | DECIMAL | DECIMAL   |
| MONEY      | MONEY   | MONEY    | MONEY   | MONEY   | MONEY   | MONEY      | MONEY | MONEY   | MONEY     |
| BIGINT     | DECIMAL | DECIMAL  | DECIMAL | DECIMAL | DECIMAL | DECIMAL    | MONEY | BIGINT  | BIGINT    |
| BIGSERIAL  | DECIMAL | DECIMAL  | DECIMAL | DECIMAL | DECIMAL | DECIMAL    | MONEY | BIGINT  | BIGSERIAL |

## Generic CASE Expressions

A generic CASE expression tests for a true condition in a WHEN clause. If it finds a true condition, it returns the result specified in the THEN clause.

Generic CASE Expression

**CASE**

**WHEN**

Condition<sup>581</sup>

**THEN**

*expr* **NULL**

**ELSE**

*expr* **NULL**

**END**

581. See [Condition on page 1144](#)

| Element     | Description                            | Restrictions  | Syntax                                  |
|-------------|--|---|---|
| <i>expr</i> | Expression that returns some data type | Data type of <i>expr</i> in a THEN clause must be compatible with data types of expressions in other THEN clauses | <a href="#">Expression on page 1193</a> |

The database server processes the WHEN clauses in the order that they appear in the statement. If the search condition of a WHEN clause evaluates to `TRUE`, the database server uses the value of the corresponding THEN expression as the result, and stops processing the CASE expression.

If no WHEN condition evaluates to `TRUE`, the database server uses the ELSE expression as the overall result. If no WHEN condition evaluates to `TRUE`, and no ELSE clause was specified, the returned CASE expression value is NULL. You can use the IS NULL condition to handle NULL results. For information on how to handle NULL values, see [IS NULL and IS NOT NULL Conditions on page 1152](#).

The next example shows a generic CASE expression in the Projection clause.

In this example, the user retrieves the name and address of each customer as well as a calculated number that is based on the number of problems that exist for that customer:

```
SELECT cust_name,
CASE
  WHEN number_of_problems = 0
    THEN 100
  WHEN number_of_problems > 0 AND number_of_problems < 4
    THEN number_of_problems * 500
  WHEN number_of_problems >= 4 and number_of_problems <= 9
    THEN number_of_problems * 400
  ELSE
    (number_of_problems * 300) + 250
END,
cust_address
FROM custtab
```

In a generic CASE expression, all the results should be of the same data type, or they should evaluate to a common compatible data type. If the results in all the WHEN clauses are not of the same data type, or if they do not evaluate to values of mutually compatible types, an error occurs. For more information on the compatibility of returned data types, see [CASE expressions data type compatibility on page 1228](#).

## Linear CASE Expressions

A linear CASE expression compares the value of the expression that follows the CASE keyword with an expression in a WHEN clause.

Linear CASE Expression

**CASE***expr*

**WHEN***expr***THEN**

*expr* **NULL**

**ELSE**

*expr* **NULL**

**END**

| Element     | Description                                       | Restrictions   | Syntax                                  |
|-------------|---|--|---|
| <i>expr</i> | Expression that returns a value of some data type | Data type of <i>expr</i> that follows the WHEN keyword must be compatible with data type of the expression that follows the CASE keyword. Data type of <i>expr</i> in the THEN clause must be compatible with data types of expressions in other THEN clauses. | <a href="#">Expression on page 1193</a> |

The database server evaluates the expression that follows the CASE keyword, and then processes the WHEN clauses sequentially. If an expression after the WHEN keyword returns the same value as the expression that follows the CASE keyword, the database server uses the value of the expression that follows the THEN keyword as the overall result of the CASE expression. Then the database server stops processing the CASE expression.

If none of the WHEN expressions return the same value as the expression that follows the CASE keyword, the database server uses the expression of the ELSE clause as the overall result of the CASE expression (or, if no ELSE clause was specified, the returned value of the CASE expression is NULL).

The next example shows a linear CASE expression in the projection list of the Projection clause of a SELECT statement. For each movie in a table of movie titles, the query returns the title, the cost, and the type of the movie. The statement uses a CASE expression to derive the type of each movie:

```
SELECT title, CASE movie_type
  WHEN 1 THEN 'HORROR'
  WHEN 2 THEN 'COMEDY'
  WHEN 3 THEN 'ROMANCE'
  WHEN 4 THEN 'WESTERN'
  ELSE 'UNCLASSIFIED'
END,
our_cost FROM movie_titles;
```

In linear CASE expressions, the data types of WHEN clause expressions must be compatible with that of the expression that follows the CASE keyword.

## COALESCE Function

The COALESCE function returns the first non-NULL value from a series of expressions.

## COALESCE Function

**COALESCE** (*expression*  
*, expression*  
 )

| Element           | Description   | Restrictions                                       | Syntax                                  |
|-------------------|---|--|---|
| <i>expression</i> | An expression that returns a value of a compatible data type with the other expressions in the function | Cannot be a host variable or a BYTE or TEXT object | <a href="#">Expression on page 1193</a> |

The expressions are evaluated in the order in which they are specified, and the result of the function is the first value that is not null. The result of the COALESCE function returns NULL only if all the arguments are null. The expressions can return any data type that can be cast to a common compatible data type.

Suppose that the **addr** column of the **employees** table has NULL values in some rows, and that you want to print the label `Address unknown` for these rows. Run the following SELECT statement to display the label `Address unknown` when the **addr** column has a NULL value:

```
SELECT fname, COALESCE (addr, 'Address unknown') AS address
FROM employees;
```

## NVL Function

The **NVL** expression returns different results, depending on whether its first argument evaluates to NULL.

## NVL Function

**NVL**(*expr1*, *expr2*)

| Element                      | Description  | Restrictions                                       | Syntax                                  |
|------------------------------|--|--|---|
| <i>expr1</i><br><i>expr2</i> | Expressions that return values of a compatible data type | Cannot be a host variable or a BYTE or TEXT object | <a href="#">Expression on page 1193</a> |

**NVL** evaluates *expression1*. If *expression1* is not NULL, then **NVL** returns the value of *expression1*. If *expression1* is NULL, **NVL** returns the value of *expression2*. The expressions *expression1* and *expression2* can be of any data type, as long as they can be cast to a common compatible data type.

Suppose that the **addr** column of the **employees** table has NULL values in some rows, and the user wants to be able to print the label `Address unknown` for these rows. The user enters the following SELECT statement to display the label `Address unknown` when the **addr** column has a NULL value:

```
SELECT fname, NVL (addr, 'Address unknown') AS address
FROM employees;
```

## NULLIF Function

The **NULLIF** expression returns different results, depending on whether its two arguments are equal.

NULLIF Function

**NULLIF**(*expr1*, *expr2*)

| Element                      | Description  | Restrictions                       | Syntax                                  |
|------------------------------|--|------------------------------------|---|
| <i>expr1</i><br><i>expr2</i> | Expressions that return values of a compatible data type | Cannot be a BYTE or TEXT data type | <a href="#">Expression on page 1193</a> |

**NULLIF** evaluates its two arguments, *expr1* and *expr2*.

- If their values are equal, then **NULLIF** returns NULL.
- If their values are not equal, then **NULLIF** returns *expr1*.

The *expr1* and *expr2* arguments can be of any data type for which a built-in comparison function exists, or any two data types that can be cast to a compatible data type that has a built-in comparison function.

The following example uses the **NULLIF** function to convert Boolean FALSE values ('f') to NULL values:

```
SELECT name, answer, NULLIF(answer, 'f') FROM booktab;
```

Here the first argument is a Boolean column expression that can have true ('t') or false ('f') values, and the second Boolean argument is always 'f' (for FALSE). For rows that have 'f' in the **answer** column, the value returned by the **NULLIF** function will be NULL (because the NULL value is returned when the arguments are equal). For rows that have 't' as the first argument, however, the value returned by **NULLIF** is always 't', because the two arguments cannot be equal when one is 't' and the other is 'f'; the first argument is returned when the two values are not equal.

## DECODE Function

The **DECODE** expression is similar to the CASE expression in that it can print different results depending on the values found in a specified column.

DECODE Function

```
DECODE(expr,
, when_expr,
then_expr NULL
, NULL
, else_expr
)
```

| Element   | Description  | Restrictions   | Syntax                                  |
|---|--|--|---|
| <i>expr</i> , <i>else_expr</i> ,<br><i>then_expr</i> , <i>when_expr</i> | Expressions whose values and data types can be evaluated | Data types of <i>when_expr</i> and <i>expr</i> must be compatible, as must <i>then_expr</i> and <i>else_expr</i> . Value of <i>when_expr</i> cannot be a NULL. | <a href="#">Expression on page 1193</a> |

The expressions *expr*, *when\_expr*, and *then\_expr* are required. **DECODE** evaluates *expr* and compares it to *when\_expr*. If the value of *when\_expr* matches the value of *expr*, then **DECODE** returns *then\_expr*.

The expressions *when\_expr* and *then\_expr* are an expression pair, and you can specify any number of expression pairs in the **DECODE** function. In all cases, **DECODE** compares the first member of the pair against *expr* and returns the second member of the pair if the first member matches *expr*.

If no expression matches *expr*, **DECODE** returns *else\_expr*. If no expression matches *expr* and you specified no *else\_expr*, then **DECODE** returns NULL.

You can specify any data type for the arguments, but two restrictions exist:

- All instances of *when\_expr* must have the same data type, or a common compatible type must exist. All instances of *when\_expr* must also have the same (or a compatible) data type as *expr*.
- All instances of *then\_expr* must have the same data type, or a common compatible type must exist. All instances of *then\_expr* must also have the same (or a compatible) data type as *else\_expr*.

The **DECODE** function uses the same data type compatibility rules as a **CASE** expression. For more information on the compatibility of returned data types, see [CASE expressions data type compatibility on page 1228](#).

## Example

Suppose that a user wants to convert descriptive values in the **evaluation** column of the **students** table to numeric values in the output. The following table shows the contents of the **students** table.

| firstname | evaluation | firstname | evaluation |
|-----------|------------|-----------|------------|
| Edward    | Great      | Mary      | Good       |
| Joe       | Not done   | Jim       | Poor       |

The user now enters a query with the **DECODE** function to convert the descriptive values in the **evaluation** column to numeric equivalents:

```
SELECT firstname, DECODE(evaluation,
  'Poor', 0,
  'Fair', 25,
  'Good', 50,
  'Very Good', 75,
  'Great', 100,
  -1) as grade
FROM students;
```

The following table shows the output of this **SELECT** statement.

| firstname | evaluation | firstname | evaluation |
|-----------|------------|-----------|------------|
| Edward    | 100        | Mary      | 50         |
| Joe       | -1         | Jim       | 0          |

## Constant Expressions

Certain expressions that return a fixed value are called *constant expressions*. These include variant function operators that read the system clock, but that are valid in contexts where literal constants are also valid.

Among these expressions are the following operators (or *system constants*) whose returned values are determined at runtime:

- **CURRENT** returns the current time and date from the system clock.
- **CURRENT\_ROLE** returns the name of the role, if any, whose privileges are enabled for the current user.
- **CURRENT\_USER** is a synonym for **USER**.
- **DEFAULT\_ROLE** returns the name of the role, if any, that is the default role for the current user.
- **DBSERVERNAME** returns the name of the current database server.
- **SITENAME** is a synonym for **DBSERVERNAME**.
- **SYSDATE** reads the DATETIME value from the system clock like the **CURRENT** operator, but has a different default precision.
- **TODAY** returns the current calendar date from the system clock.
- **USER** returns the login name (also called the *authorization identifier*) of the current user.

Besides these operators, the term *constant expression* can also refer to a quoted string, to a literal value, or to the **UNITS** operator with its operands.

The Constant Expression segment has the following syntax.

Constant Expressions

Quoted String<sup>582</sup>

Literal Number<sup>583</sup>

**USER CURRENT\_USER**

584

**CURRENT\_ROLE DEFAULT\_ROLE**

584

**SITENAME DBSERVERNAME**

**TODAY**

589. See [Literal Collection on page 1412](#)

| Element          | Description   | Restrictions   | Syntax  |
|------------------|---|--|---|
| <i>precision</i> | Precision of the returned DATETIME expression                                     | On Windows™ systems the maximum scale of seconds is FRACTION(3).                           | <a href="#">DATETIME Field Qualifier on page 1191</a> |
| <i>sequence</i>  | Name of a sequence  | Must exist in current database   | <a href="#">Identifier on page 1456</a>               |
| <i>synonym</i>   | Synonym for the name of a sequence  | Must exist in current database   | <a href="#">Identifier on page 1456</a>               |
| <i>time_unit</i> | Keyword to specify time unit: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, or FRACTION | Must be one of the keywords at left. Case insensitive but cannot be enclosed within quotes | See the <b>Restrictions</b> column.                   |

## Quoted String

The following examples show quoted strings as expressions:

```
SELECT 'The first name is ', fname FROM customer;

INSERT INTO manufact VALUES ('SPS', 'SuperSport');

UPDATE cust_calls SET res_dtime = '2007-1-1 10:45'
WHERE customer_num = 120 AND call_code = 'B';
```

For more information, see [Quoted String on page 1424](#).

## Literal Number

A literal number specifies a numeric value.

The following examples show literal numbers as expressions:

```
INSERT INTO items VALUES (4, 35, 52, 'HRO', 12, 4.00);

INSERT INTO acreage VALUES (4, 5.2e4);

SELECT unit_price + 5 FROM stock;

SELECT -1 * balance FROM accounts;
```

For more information, see [Literal Number on page 1419](#).

## USER or CURRENT\_USER Operator

The **USER** operator returns a string containing the login name (also called the authorization identifier) of the current user who is running the process. The **CURRENT\_USER** operator is a synonym of the **USER** operator.

The following statements show how you might use the **USER** operator:

```
INSERT INTO cust_calls VALUES
  (221,CURRENT_USER,'B','Decimal point off', NULL, NULL);

SELECT * FROM cust_calls WHERE user_id = USER;

UPDATE cust_calls SET user_id = USER WHERE customer_num = 220;
```

The **USER** operator does not change the lettercase of a user ID. If you use **USER** in an expression and the current user is **Robertm**, the **USER** operator returns **Robertm**, not **robertm** or **ROBERTM**.

If you specify **USER** as a default column value, *column* must be of type CHAR, VARCHAR, NCHAR, NVARCHAR, or LVARCHAR.

If you specify **USER** as the default value for a column, the size of *column* should not be less than 32 bytes. You risk getting an error during operations such as INSERT or ALTER TABLE if the column length is too small to store the default value.

In an ANSI-compliant database, if you do not enclose the *owner* name in quotation marks, the name of the table owner is stored as uppercase letters. If you use the **USER** operator as part of a condition, you must be sure that the way the *user* name is stored matches what the **USER** operator returns with respect to lettercase.

## CURRENT\_ROLE Operator

The **CURRENT\_ROLE** operator returns a string that contains the name of the currently enabled role of the user who is running the session. This *role* was either set in the session explicitly, using the SET ROLE statement, or else implicitly as a default role when the current user connected to the database. If the user holds no role, or if no role that was granted to the user is currently enabled, **CURRENT\_ROLE** returns a NULL value. If the user has been granted no role individually, but a default role has been granted to PUBLIC, and this default role has been explicitly or implicitly enabled, **CURRENT\_ROLE** returns the name of this default role.

The next statement shows how you might use the **CURRENT\_ROLE** operator:

```
select CURRENT_ROLE FROM systables WHERE tabid = 1;
```

The **CURRENT\_ROLE** operator does not change the lettercase of the identifier of a role. If you use **CURRENT\_ROLE** in an expression and your current role is **Czarina**, the **CURRENT\_ROLE** operator returns **Czarina**, not **czarina**.

If you specify **CURRENT\_ROLE** as the default value for a column, the column must have a CHAR, VARCHAR, LVARCHAR, NCHAR, or NVARCHAR data type. Because the name of a role is an authorization identifier, truncation might occur if the column length is less than 32 bytes.

## DEFAULT\_ROLE Operator

The **DEFAULT\_ROLE** operator evaluates to a string that contains the name of the default role that has been granted to the user who is running the session. This default role need not be currently enabled, but it must not have been revoked since the most recent GRANT DEFAULT ROLE statement that referenced the user or PUBLIC in the TO clause.

If no default role is explicitly defined for the current user, but PUBLIC has a default role, **DEFAULT\_ROLE** returns the default role of PUBLIC.

If the user has no default role, or if the default role that was most recently granted to the user explicitly, or as PUBLIC, was subsequently revoked by the REVOKE DEFAULT ROLE statement, **DEFAULT\_ROLE** returns a NULL value. If the user has been granted no default role individually, but a default role has been granted to PUBLIC, the **DEFAULT\_ROLE** operator returns the name of this default role. If no default role is currently defined for the user nor for PUBLIC, however, **DEFAULT\_ROLE** returns NULL.

The SET ROLE statement has no effect on the **DEFAULT\_ROLE** operator, but any access privileges of the default role are not necessarily available to the user if SET ROLE has activated some other role, or if SET ROLE specified NULL or NONE as the current role of the user.

The next statements show how you might use the **DEFAULT\_ROLE** operator:

```
select DEFAULT_ROLE from systables where tabid = 1;
```

**DEFAULT\_ROLE** does not change the lettercase of the identifier of a role.

If you specify **DEFAULT\_ROLE** as the default value for a column, the column must have a CHAR, VARCHAR, LVARCHAR, NCHAR, or NVARCHAR data type. Because the name of a role is an authorization identifier, truncation might occur if the column width is less than 32 bytes. (See [Owner name on page 1488](#) for the syntax of authorization identifiers.)

## DBSERVERNAME and SITENAME Operators

The **DBSERVERNAME** operator returns the SQL identifier of the database server, as defined by the DBSERVERNAME parameter in the ONCONFIG file for the Informix® instance where the current database resides, or as specified in the **INFORMIXSERVER** environment variable. **SITENAME** is a keyword synonym for the **DBSERVERNAME** operator.

You can use the **DBSERVERNAME** operator to specify the location of a table, to put information into a table, or to extract information from a table. You can insert **DBSERVERNAME** into a simple character field or use it as a default value for a column.

If you specify **DBSERVERNAME** as a default column value in the CREATE TABLE or ALTER TABLE statements, the column must be a CHAR, VARCHAR, LVARCHAR, NCHAR, or NVARCHAR data type.

If you specify **DBSERVERNAME** or **SITENAME** as the default value for a column, the size of the column should be at least 128 bytes long. You risk getting an error message during INSERT and ALTER TABLE operations if the length of the column is too small to store the default value.

The following examples use **DBSERVERNAME** or **SITENAME** in DML statements.

- The first SELECT statement returns the name of the database server instance where the **customer** table resides. (Because the query is not restricted by a WHERE clause, it returns the same **DBSERVERNAME** value for every row in the table. If you include the DISTINCT keyword in the projection clause, the query returns **DBSERVERNAME** only once.)
- The second statement adds a row that contains the name of the current database server to a table.
- The third statement returns all rows that have the name of the current database server in the **host\_tab.site\_col** column.
- The last statement changes to the name of the current database server the value of the **customer.company** column in the row whose SERIAL value of **customer\_num** is 120:

```
SELECT DBSERVERNAME FROM customer;

INSERT INTO host_tab VALUES ('1', SITENAME);

SELECT * FROM host_tab WHERE site_col = DBSERVERNAME;

UPDATE customer SET company = SITENAME
WHERE customer_num = 120;
```

## TODAY Operator

Use the **TODAY** operator to return the system date as a DATE data type. If you specify **TODAY** as a default column value, the column must be a DATE column.

The following examples show how you might use the **TODAY** operator in an INSERT, UPDATE, or SELECT statement:

```
UPDATE orders (order_date) SET order_date = TODAY
WHERE order_num = 1005;

INSERT INTO orders VALUES
(0, TODAY, 120, NULL, N, '1AUE217', NULL, NULL, NULL, NULL);

SELECT * FROM orders WHERE ship_date = TODAY;
```

For code examples of setting non-default time zones, see [CURRENT Operator on page 1240](#).

## CURRENT Operator

The **CURRENT** operator returns a DATETIME value with the date and time of day, showing the current instant.

If you do not specify a DATETIME qualifier, the default qualifier is YEAR TO FRACTION(3). The USEOSTIME configuration parameter specifies whether or not the database server uses subsecond precision when it obtains the current time from the operating system. For more information on the USEOSTIME configuration parameter, see your .

You can use **CURRENT** in any context where a literal DATETIME is valid. (See [Literal DATETIME on page 1414](#)). If you specify **CURRENT** as the default value for a column, it must be a DATETIME column and the qualifier of **CURRENT** must match the column qualifier, as the following example shows:

```
CREATE TABLE new_acct (col1 INT, col2 DATETIME YEAR TO DAY
    DEFAULT CURRENT YEAR TO DAY);
```

**CURRENT** is always evaluated in the database server where the current database is located. If the current database is in a remote database server, the returned value is from the remote host.

SQL is not a procedural language, and **CURRENT** might not execute in the lexical order of its position in a statement. You should not use **CURRENT** to mark the start, the end, nor a specific point in the execution of an SQL statement.

If you use the **CURRENT** operator in more than once in a single statement, identical values might be returned by each instance of **CURRENT**. You cannot rely on **CURRENT** to return distinct values each time it executes.

The returned value is based on the system clock and is fixed when the SQL statement that specifies **CURRENT** starts execution. For example, any call to **CURRENT** from inside the SPL function that an EXECUTE FUNCTION (or EXECUTE PROCEDURE) statement invokes returns the value of the system clock when the SPL function starts.

On UNIX™ and Linux™ systems, the precision of the value returned by the **CURRENT** operator is determined by its DATETIME Qualifier, which can range from a single time unit (such as MONTH TO MONTH) up to YEAR TO FRACTION (5). The system clock on Windows™, however, returns only millisecond precision. Even if you specify "FRACTION(5)" in the DATETIME Qualifier, the **CURRENT** operator on Windows™ supports no greater than "FRACTION(3)" precision.

If your platform does not provide a system call that returns the current time with subsecond precision, **CURRENT** returns a zero for the FRACTION field.

In the following example, the first statement uses **CURRENT** in a WHERE condition. The second statement uses **CURRENT** as an argument to the **DAY** function. The last query selects rows whose **call\_dtime** value is within a range from the beginning of 2007 to the current instant:

```
DELETE FROM cust_calls WHERE res_dtime < CURRENT YEAR TO MINUTE;

SELECT * FROM orders WHERE DAY(ord_date) < DAY(CURRENT);

SELECT * FROM cust_calls WHERE call_dtime
    BETWEEN '2007-1-1 00:00:00' AND CURRENT;
```

For more information, see [DATETIME Field Qualifier on page 1191](#).

## SYSDATE Operator

The **SYSDATE** operator returns the current DATETIME value from the system clock. **SYSDATE** is identical to the **CURRENT** operator, except that the default precision of **SYSDATE** is YEAR TO FRACTION(5), while the default precision of **CURRENT** is YEAR TO FRACTION(3).

On Windows™ platforms that do not support a *seconds* scale greater than FRACTION(3), **SYSDATE** is in effect a synonym for the **CURRENT** operator,

You can use **SYSDATE** in any context where the **CURRENT** operator is valid.

The SQL statements in the following example use the **SYSDATE** operator to specify the default values for two DATETIME columns of a database table, and to insert a new row into the table:

```
CREATE TABLE tab1 (
  id SERIAL,
  value CHAR(20),
  time1 DATETIME YEAR TO FRACTION(5) DEFAULT SYSDATE,
  time2 DATETIME YEAR TO SECOND DEFAULT SYSDATE YEAR TO SECOND
);

INSERT INTO tab1 VALUES (0, 'description', SYSDATE, SYSDATE);
```

The following query accesses the table that was created in the previous example:

```
SELECT SYSDATE AS sysdate, * FROM tab1;
```

The results are sensitive to the date and time when the INSERT and SELECT statements are issued, but the query could return these values on September 23, 2007:

```
sysdate  2007-09-23 21:30:23.00000
id        1
value     description
time1     2007-09-23 21:29:27.00000
time2     2007-09-23 21:29:27
```

The next query accesses the same table, using **SYSDATE** in the WHERE clause as an argument to the **DAY** function:

```
SELECT *, DAY(time1) AS day FROM tab1
WHERE DAY(time1) = DAY(SYSDATE);
```

The query could return these values on September 23, 2007:

```
id        1
value     description
time1     2007-09-23 21:29:27.00000
time2     2007-09-23 21:29:27
day       23
```

Only Informix® supports **SYSDATE**. Except for its name and its default precision, the description of the **CURRENT** operator in this document also describes the **SYSDATE** operator.

## Literal DATETIME

A literal DATETIME specifies the value of an DATETIME data type, including its qualifying time-units.

The following examples show literal DATETIME values as expressions:

```
SELECT DATETIME (2007-12-6) YEAR TO DAY FROM customer;
```

```

UPDATE cust_calls SET res_dtime = DATETIME (2008-07-07 10:40)
    YEAR TO MINUTE
WHERE customer_num = 110
AND call_dtime = DATETIME (2008-07-07 10:24) YEAR TO MINUTE;

SELECT * FROM cust_calls
WHERE call_dtime
    = DATETIME (2008-12-25 00:00:00) YEAR TO SECOND;

```

For more information, see [Literal DATETIME on page 1414](#).

## Literal INTERVAL

A literal INTERVAL specifies the value of an INTERVAL data type, including its qualifying time-units.

The following examples each use a literal INTERVAL as an expression:

```

INSERT INTO manufact VALUES ('CAT', 'Catwalk Sports',
    INTERVAL (16) DAY TO DAY);

SELECT lead_time + INTERVAL (5) DAY TO DAY FROM manufact;

```

The second example adds five days to each value of **lead\_time** selected from the **manufact** table.

For more information, see [Literal INTERVAL on page 1418](#).

## UNITS Operator

The UNITS operator specifies an INTERVAL value whose precision includes only one time unit. You can use UNITS in arithmetic expressions that increase or decrease one of the time units in an INTERVAL or DATETIME value.

If the *num* operand is not an integer, it is truncated to the largest whole number that is the same as (or nearer to zero than) the specified value when the database server evaluates the expression.

In the following example, the first SELECT statement uses the UNITS operator to select all the **manufacturer.lead\_time** values, increased by five days. The second SELECT statement finds all the calls that were placed more than 30 days ago.

If the expression in the WHERE clause returns a value greater than 99 (maximum number of days), the query fails. The last statement increases the lead time for the ANZA manufacturer by two days:

```

SELECT lead_time + 5 UNITS DAY FROM manufact;

SELECT * FROM cust_calls WHERE (TODAY - call_dtime) > 30 UNITS DAY;

UPDATE manufact SET lead_time = 2 UNITS DAY + lead_time
    WHERE manu_code = 'ANZ';

```

## NEXTVAL and CURRVAL Operators

You can access the value of a sequence using the **NEXTVAL** or **CURRVAL** operators in SQL statements. You must qualify **NEXTVAL** or **CURRVAL** with the name (or synonym) of a sequence object that exists in the same database, using the format *sequence*.**NEXTVAL** or *sequence*.**CURRVAL**. An expression can also qualify *sequence* by the *owner* name, as in **zelaine.myseq.CURRVAL**. You can specify the SQL identifier of *sequence* or a valid synonym, if one exists.

In an ANSI-compliant database, you must qualify the name of the *sequence* with the name of its owner (*owner.sequence*) if you are not the owner.

To use **NEXTVAL** or **CURRVAL** with a sequence, you must have the Select privilege on the sequence or have the DBA privilege on the database. For information about sequence-level privileges, see the [GRANT statement on page 592](#) statement.

### Examples

In the following examples, it is assumed that no other user is concurrently accessing the sequence and that the user executes the statements consecutively.

These examples are based on the following sequence object and table:

```
CREATE SEQUENCE seq_2
  INCREMENT BY 1 START WITH 1
  MAXVALUE 30 MINVALUE 0
  NOCYCLE CACHE 10 ORDER;

CREATE TABLE tab1 (col1 int, col2 int);
INSERT INTO tab1 VALUES (0, 0);
```

You can use **NEXTVAL** (or **CURRVAL**) in the Values clause of an INSERT statement, as the following example shows:

```
INSERT INTO tab1 (col1, col2)
  VALUES (seq_2.NEXTVAL, seq_2.NEXTVAL);
```

In the previous example, the database server inserts an incremented value (or the first value of the sequence, which is **1**) into the **col1** and **col2** columns of the table.

You can use **NEXTVAL** (or **CURRVAL**) in the SET clause of the UPDATE statement, as the following example shows:

```
UPDATE tab1
  SET col2 = seq_2.NEXTVAL
  WHERE col1 = 1;
```

In the previous example, the incremented value of the **seq\_2** sequence, which is **2**, replaces the value in **col2** where **col1** is equal to **1**.

The following example shows how you can use **NEXTVAL** and **CURRVAL** in the Projection clause of the SELECT statement:

```
SELECT seq_2.CURRVAL, seq_2.NEXTVAL FROM tab1;
```

In the previous example, the database server returns two rows of incremented values, **3** and **4**, from both the **CURRVAL** and **NEXTVAL** expressions. For the first row of **tab1**, the database server returns the incremented value **3** for **CURRVAL** and **NEXTVAL**; for the second row of **tab1**, it returns the incremented value **4**.

---

**Related reference**[ALTER SEQUENCE statement on page 95](#)[CREATE SEQUENCE statement on page 326](#)[RENAME SEQUENCE statement on page 716](#)

## Using NEXTVAL

To access a sequence for the first time, you must refer to *sequence*.**NEXTVAL** before you can refer to *sequence*.**CURRVAL**. The first reference to **NEXTVAL** returns the initial value of the sequence. Each subsequent reference to **NEXTVAL** increments the value of the sequence by the defined *step* and returns a new incremented value of the sequence.

You can increment a given sequence only once within a single SQL statement. Even if you specify *sequence*.**NEXTVAL** more than once within a single statement, the sequence is incremented only once, so that every occurrence of *sequence*.**NEXTVAL** in the same SQL statement returns the same value.

Except for the case of multiple occurrences within the same statement, every *sequence*.**NEXTVAL** expression increments the *sequence*, regardless of whether you subsequently commit or roll back the current transaction.

If you specify *sequence*.**NEXTVAL** in a transaction that is ultimately rolled back, some sequence numbers might be skipped.

## Using CURRVAL

Any reference to **CURRVAL** returns the current value of the specified sequence, which is the value that your last reference to **NEXTVAL** returned. After you generate a new value with **NEXTVAL**, you can continue to access that value using **CURRVAL**, regardless of whether another user increments the sequence.

If both *sequence*.**CURRVAL** and *sequence*.**NEXTVAL** occur in an SQL statement, the sequence is incremented only once. In this case, each *sequence*.**CURRVAL** and *sequence*.**NEXTVAL** expression returns the same value, regardless of the order of *sequence*.**CURRVAL** and *sequence*.**NEXTVAL** within the statement.

## Concurrent Access to a Sequence

A sequence always generates unique values within a database without perceptible waiting or locking, even when multiple users refer to the same sequence concurrently. When multiple users use **NEXTVAL** to increment the sequence, each user generates a unique value that other users cannot see.

When multiple users concurrently increment the same sequence, gaps occur between the values that each user sees. For example, one user might generate a series of values, such as 1, 4, 6, and 8, from a sequence, while another user concurrently generates the values 2, 3, 5, and 7 from the same sequence object.

## Restrictions on sequence operators

**NEXTVAL** and **CURRVAL** are valid only in SQL statements, not directly in SPL statements. (But SQL statements that use **NEXTVAL** and **CURRVAL** can be used in SPL routines.) The following restrictions apply to these operators in SQL statements:

- You must have Select privilege on the *sequence*.
- In a CREATE TABLE or ALTER TABLE statement, you cannot specify **NEXTVAL** or **CURRVAL** in the following contexts:
  - In the Default clause of a column definition
  - In the definition of a check constraint.
- In a SELECT statement, you cannot specify **NEXTVAL** or **CURRVAL** in the following contexts:
  - In the projection list when the DISTINCT keyword is used
  - In the WHERE, GROUP BY, or ORDER BY clauses
  - In a subquery
  - When the UNION operator combines SELECT statements.
- You also cannot specify **NEXTVAL** or **CURRVAL** in these contexts:
  - In fragmentation expressions
  - In reference to a remote sequence object in another database.

## Literal Row

The syntax for a literal representation of the value of a named or unnamed ROW data type is described in the section [Literal Row on page 1421](#). The following examples show literal rows as expressions:

```
INSERT INTO employee VALUES
  (ROW('103 Baker St', 'San Francisco',
       'CA', 94500));

UPDATE rectangles
  SET rect = ROW(8, 3, 7, 20)
  WHERE area = 140;

EXEC SQL update table(:a_row)
  set x=0, y=0, length=10, width=20;

SELECT row_col FROM tab_b
  WHERE ROW(17, 'abc') IN (row_col);
```

For the syntax of expressions that evaluate to field values of a ROW data type, see [ROW constructors on page 1247](#).

## Literal Collection

Informix® supports expressions that are literal representations of the values of built-in or user-defined collection data types. The following examples show literal collections as expressions:

```
INSERT INTO tab_a (set_col) VALUES ("SET{6, 9, 3, 12, 4}");

INSERT INTO TABLE(a_set) VALUES (9765);

UPDATE table1 SET set_col = "LIST{3}";
```

```
SELECT set_col FROM table1
WHERE SET{17} IN (set_col);
```

For more information, see [Literal Collection on page 1412](#). For the syntax of element values, see [Collection Constructors on page 1248](#).

## Constructor Expressions

A *constructor* is a function that the database server uses to create an instance of a specific data type. The database server supports ROW constructors and collection constructors.

Constructor Expressions

**ROW**(

, Expression<sup>590</sup>

)

Collection Constructors<sup>591</sup>

## ROW constructors

You use ROW constructors to generate values for ROW-type columns.

Suppose you create the following named ROW type and a table that contains the named ROW type **row\_t** and an unnamed ROW type:

```
CREATE ROW TYPE row_t ( x INT, y INT);
CREATE TABLE new_tab
(
  col1 row_t,
  col2 ROW( a CHAR(2), b INT)
);
```

When you define a column as a named ROW type or unnamed ROW type, you must use a ROW constructor to generate values for the ROW-type column. To create a value for either a named ROW type or unnamed ROW type, you must complete the following steps:

- Begin the expression with the ROW keyword.
- Specify a value for each field of the ROW type.
- Enclose the comma-separated list of field values within parentheses.

The format of the value for each field must be compatible with the data type of the ROW field to which it is assigned.

You can use any kind of expression as a value with a ROW constructor, including literals, functions, and variables. The following examples show the use of different types of expressions with ROW constructors to specify values:

590. See [Expression on page 1193](#)

591. See [Collection Constructors on page 1248](#)

```

ROW(5, 6.77, 'HMO')

ROW(col1.lname, 45000)

ROW('john davis', TODAY)

ROW(USER, SITENAME)

```

The following statement uses literal numbers and quoted strings with ROW constructors to insert values into **col1** and **col2** of the **new\_tab** table:

```

INSERT INTO new_tab
VALUES
(
ROW(32, 65)::row_t,
ROW('CA', 34)
);

```

When you use a ROW constructor to generate values for a named ROW type, you must explicitly cast the ROW value to the appropriate named ROW type. The cast is necessary to generate a value of the named ROW type. To cast the ROW value as a named ROW type, you can use the cast operator ( :: ) or the CAST AS keywords, as the following examples show:

```

ROW(4,5)::row_t
CAST (ROW(3,4) AS row_t)

```

You can use a ROW constructor to generate ROW type values in INSERT, UPDATE, and SELECT statements. In the next example, the WHERE clause of a SELECT statement specifies a ROW type value that is cast as type **person\_t**:

```

SELECT * FROM person_tab
WHERE col1 = ROW('charlie','hunter')::person_t;

```

For more information on using ROW constructors in INSERT and UPDATE statements, see the INSERT and UPDATE statements in this document. For information on named ROW types, see the CREATE ROW TYPE statement. For information on unnamed ROW types, see the discussion of the ROW data type in the *Informix® Guide to SQL: Reference*. For task-oriented information on named ROW types and unnamed ROW types, see the *Informix® Database Design and Implementation Guide*.

## Collection Constructors

Use a collection constructor to specify values for a collection column.

Collection Constructors

### SET MULTISSET LIST

```

{
, Expression592
}

```

592. See [Expression on page 1193](#)

You can use collection constructors in the WHERE clause of the SELECT statement and the VALUES clause of the INSERT statement. You can also pass collection constructors to UDRs.

This table differentiates the types of collections that you can construct.

| Keyword  | Description  |
|----------|--|
| SET      | Indicates a collection of elements with the following qualities: <ul style="list-style-type: none"> <li>• The collection must contain unique values.</li> <li>• Elements have no specific order associated with them.</li> </ul>   |
| MULTISET | Indicates a collection of elements with the following qualities: <ul style="list-style-type: none"> <li>• The collection can contain duplicate values.</li> <li>• Elements have no specific order associated with them.</li> </ul> |
| LIST     | Indicates a collection of elements with the following qualities: <ul style="list-style-type: none"> <li>• The collection can contain duplicate values.</li> <li>• Elements have ordered positions.</li> </ul>                      |

The element type of the collection can be any built-in or extended data type. You can use any kind of expression with a collection constructor, including literals, functions, and variables.

When you use a collection constructor with a list of expressions, the database server evaluates each expression to its equivalent literal form and uses the literal values to construct the collection.

You specify an empty collection with a set of empty braces ( {} ).

Elements of a collection cannot be NULL. If a collection element evaluates to a NULL value, the database server returns an error.

The element type of each expression must all be exactly the same data type. To accomplish this, cast the entire collection constructor expression to a collection type, or cast individual element expressions to the same type. If the database server cannot determine that the collection type and the element types are homogeneous, then the collection constructor returns an error. In the case of host variables, this determination is made at bind time when the client declares the element type of the host variable.

An exception to this restriction can occur when some elements of a collection are VARCHAR data types but others are longer than 255 bytes. Here the collection constructor can assign a CHAR(*n*) type to all elements, for *n* the length in bytes of the longest element. (But see [Collection Data Types on page 1189](#) for an example based on this exception, where the user avoids fixed-length CHAR elements by an explicit cast to the LVARCHAR data type.)

## Examples of Collection Constructors

The following example shows that you can construct a collection with various expressions, if the resulting values are of the same data type:

```
CREATE FUNCTION f (a int) RETURNS int;
  RETURN a+1;
END FUNCTION;
CREATE TABLE tab1 (x SET(INT NOT NULL));
INSERT INTO tab1 VALUES
(
SET{10,
  1+2+3,
  f(10)-f(2),
  Sqrt(100) +POW(2,3),
  (SELECT tabid FROM systables WHERE tabname = 'sysusers'),
  'T'::BOOLEAN::INT}
);
SELECT * FROM tab1 WHERE
  x=SET{10,
    1+2+3,
    f(10)-f(2),
    Sqrt(100) +POW(2,3),
    (SELECT tabid FROM systables WHERE tabname = 'sysusers'),
    'T'::BOOLEAN::INT}
};
```

This assumes that a cast from BOOLEAN to INT exists. (For a more restrictive syntax to specify collection values , see [Literal Collection on page 1412.](#))

## NULL Keyword

The NULL keyword is valid in most contexts where you can specify a value. What it specifies, however, is the absence of any value (or an unknown or missing value).

NULL Keyword

### NULL

Within SQL, the keyword NULL is the only syntactic mechanism for accessing a NULL value. NULL is not equivalent to zero, nor to any specific value. In ascending ORDER BY operations, NULL values precede any non-NULL value; in descending sorts, NULL values follow any non-NULL value. In GROUP BY operations, all NULL values are grouped together. (Such groups might in fact be logically heterogeneous, if they include missing or unknown values.)

The keyword NULL is a global symbol in the syntactic context of expressions, meaning that its scope of reference is global.

Every data type, whether built-in or user-defined, can represent a NULL value. HCL Informix® supports cast expressions in the projection list. This means that users can write expressions of the form NULL::*datatype*, in which *datatype* is any data type known to the database server.

HCL Informix® supports the typed NULL keyword in general expressions. NULL alone in these scenarios results in a -201 syntax error. As a result, if null is defined as a column name or a procedure name, it must be referenced with a table alias. Otherwise, it returns a -201 syntax error. The behavior is summarized in the following examples and results:

```
create table tab1 (a int, null int);
create table tab2 (a int, b int);
```

**Table 21. NULL behavior**

| Statement   | Result            |
|---|-------------------|
| <code>select null from tab1 where a = 1</code>      | -201 syntax error |
| <code>select * from tab1 where null = a</code>      | -201 syntax error |
| <code>select * from tab1 where tab1.null = a</code> | Valid syntax      |
| <code>select * from tab1 where a = null</code>      | -201 syntax error |
| <code>select * from tab2 where a = null</code>      | -201 syntax error |
| <code>select * from tab2 where null = a</code>      | -201 syntax error |
| <code>select * from tab2 where null = a</code>      | -201 syntax error |
| <code>select NULL::int from tab1</code>             | Valid syntax      |
| <code>select NULL::int from tab1</code>             | Valid syntax      |
| <code>select 1 + NULL::int from tab1</code>         | Valid syntax      |
| <code>select 1 + NULL::int from tab2</code>         | Valid syntax      |
| <code>select NULL::int + 1 from tab1</code>         | Valid syntax      |

HCL Informix® prohibits the redefinition of NULL, because allowing such definition would restrict the global scope of the NULL keyword. For this reason, any mechanism that restricts the global scope or redefines the scope of the keyword NULL will syntactically disable any cast expression involving a NULL value. You must ensure that the occurrence of the keyword NULL receives its global scope in all expression contexts.

For example, consider the following SQL code:

```
CREATE TABLE newtable
(
  null int
);

SELECT null, null::int FROM newtable;
```

The CREATE TABLE statement is valid, because the column identifiers have a scope of reference that is restricted to the table definition; they can be accessed only within the scope of a table.

```

```
MOD (10,3)
```

## Algebraic Functions

Algebraic functions take one or more arguments of numeric data types. Besides supporting numeric arguments, the **CEIL** and **FLOOR** functions can also take character string arguments that can be converted to DECIMAL values, and the **ROUND** and **TRUNC** functions can also take DATE or DATETIME arguments.

| <i>sqr_radical</i>         | Number with a real square root   | A nonnegative real number  | <a href="#">Expression on page 1193</a>     |

## ABS Function

The ABS function returns the absolute value of its numeric argument, returning the same data type as its argument. The query in the following example returns all orders for which a **ship\_charge** greater than \$20 was paid in cash (+) or as store credit (-).

```
SELECT order_num, customer_num, ship_charge
FROM orders WHERE ABS(ship_charge) > 20;
```

## CEIL Function

The **CEIL** function takes as its argument a numeric expression, or a string that can be converted to a DECIMAL data type, and returns the DECIMAL(32) representation of the smallest integer that is greater than or equal to its single argument.

The following query returns 33 as the smallest integer that is larger than or equal to the **CEIL** argument of 32.3:

```
SELECT CEIL(32.3) FROM systables WHERE tabid = 1;
```

The next example returns -32 as the smallest integer that is larger than or equal to the **CEIL** argument of -32.3:

```
SELECT CEIL(-32.3) FROM systables WHERE tabid = 1;
```

## FLOOR Function

The **FLOOR** function takes as its argument a numeric expression, or a string that can be converted to a DECIMAL data type, and returns the DECIMAL(32) representation of the largest integer that is smaller than or equal to its single argument.

The following query returns 32 as the largest integer that is smaller than or equal to the **FLOOR** argument of 32.3:

```
SELECT FLOOR(32.3) FROM systables WHERE tabid = 1;
```

The next example returns -33 as the largest integer that is smaller than or equal to the **FLOOR** argument of -32.3:

```
SELECT FLOOR(-32.3) FROM systables WHERE tabid = 1;
```

These examples illustrate how the **FLOOR** and **CEIL** functions provide upper and lower bounds that differ by 1 when they have the same argument that has a nonzero fractional part. For an integer argument, **FLOOR** and **CEIL** return the same DECIMAL(32) representation of their argument.

## GREATEST function

The **GREATEST** function returns the maximum value in a list of expressions.

The arguments to this function must be comma-separated expressions that evaluate to compatible data types.

This is the syntax of the **GREATEST** function:

GREATEST Function

```
GREATEST(expression,
, expression
)
```

| Element           | Description                            | Restrictions  | Syntax                                  |
|-------------------|--|---|---|
| <i>expression</i> | Expression whose value can be compared | Data type cannot be a collection or a large object. | <a href="#">Expression on page 1193</a> |

The arguments must be of compatible data types. Arguments of complex data types, or BYTE, TEXT, BLOB, CLOB objects, or DISTINCT types based on any of these data types are not supported. Any user-defined data type that you specify as an argument to the **GREATEST** function must implement the **greaterthan()** function.

The database server converts the specified *expression* arguments, if necessary, to the data type of the returned value. This return data type is determined by all the operands of the *expression*, and the compatibility rule is consistent with CASE expressions.

The return value of the **GREATEST** function is its largest argument value. If one or more arguments evaluates to NULL, the result is NULL. If **GREATEST** is used to compare DATE or DATETIME values, the return value is the latest date.

### Example

Assume that table **T1** contains three columns **C1**, **C2**, and **C3** with values 1, 7, and 4. The following query returns a value of 7:

```
SELECT GREATEST (C1, C2, C3) FROM T1;
```

If column **C3** has a value of NULL instead of 4, however, the same query returns a NULL value.

## LEAST function

The LEAST function returns the minimum value in a set of values.

LEAST Function

```
LEAST(  
,expression  
expression)
```

The arguments must be compatible and each argument must be an expression that returns a value of any data type other than complex types, BYTES, TEXT, BLOB, CLOB, or a user-defined type based on any of these types. The user-defined type must implement the support function **lessthan()** in order to use the LEAST function. The selected argument is converted, if necessary, to the data type of the result. The result data type is determined by all the operands and the compatibility rule is consistent with CASE expression.

The result of the function is the smallest argument value. If at least one argument can be null, the result is null. If LEAST is used to compare dates, the return value is the earliest date.

### Example

Assume that table T1 contains three columns C1, C2, and C3 with values 1, 7, and 4. The query returns a value of 1.

```
SELECT LEAST (C1, C2, C3) FROM T1
```

If column **C3** has a value of NULL instead of 4, the same query returns a NULL value.

## MOD Function

The **MOD** function takes as arguments two real number operands, and returns the remainder from integer division of the integer part of the first argument (the *dividend*) by the integer part of the second argument (the *divisor*). The value returned is an INT data type (or INT8 for remainders outside the range of INT). The quotient and any fractional part of the remainder are discarded. The *divisor* cannot be 0. Thus, `MOD (x,y)` returns `y (modulo x)`. Make sure that any variable that receives the result is of a data type that can store the returned value.

This example tests to see if the current date is within a 30-day billing cycle:

```
SELECT MOD(TODAY - MDY(1,1,YEAR(TODAY)),30) FROM orders;
```

## POW Function

The **POW** function raises its first numeric argument, the *base*, to the power of its second numeric argument, the *exponent*. The returned value is a FLOAT data type.

The following example returns all rows from the **circles** table in which the **radius** column value implies an area less than 1,000 square units, using an approximation to pi with a scale of 4:

```
SELECT * FROM circles WHERE (3.1416 * POW(radius,2)) < 1000;
```

The function identifier **Power®** is a synonym for **POW**.

To use e, the base of natural logarithms, see [EXP Function on page 1291](#).

## ROOT Function

The **ROOT** function extracts a positive real root value, returned as a FLOAT data type, from its first numeric expression argument, the *radicand*.

If you specify a second numeric argument as the *index*, which cannot be zero, then the returned value to the power *index* is equal (within rounding error) to the *radicand* argument. If only the *radicand* argument is supplied, 2 is the default *index* value. You cannot specify zero as the value of *index*.

The first SELECT statement in the following example, which uses the default *index* value of 2, returns the positive square root of the literal number 9. The second example returns the cube root of the literal number 64.

```
SELECT ROOT(9) FROM angles;           -- square root of 9
SELECT ROOT(64,3) FROM angles;       -- cube root of 64
```

Invoking **ROOT** with only a single argument is equivalent to invoking the **SQRT** function.

## SQRT Function

The **SQRT** function returns the positive square root of its argument, which must be a non-negative numeric expression.

The following example returns the square root of 9 for each row of the **angles** table:

```
SELECT SQRT(9) FROM angles;
```

The **SQRT** function is equivalent to `ROOT(x)`, where 2 is the default value of the second argument to the **ROOT** function, specifying the index.

## ROUND Function

The **ROUND** function can reduce the precision of its first numeric, MONEY, DATE, or DATETIME argument, and returns the rounded value. If the first argument is not a number, a MONEY value, or a point in time, it must be cast to a numeric, MONEY, DATE, or DATETIME data type.

The following diagram shows the syntax of both the **ROUND** and **TRUNC** algebraic functions, which support the same syntax. Because their semantics differ, however, they can return different values from the same argument list. Only **ROUND** can return an absolute value larger than its first argument.

ROUND and TRUNC algebraic functions

### ROUND TRUNC

```
(
  num_expression date_expression
, 0
, factor
)
```

### ROUND TRUNC

```
(date_expression
, '
DD DAY MONTH YEAR
,
)
```

### ROUND TRUNC

```
(datetime_expression
, 'DD'
, '
MI HH DAY MONTH YEAR
,
)
```

| Element                    | Description  | Restrictions   | Syntax                                      |
|----------------------------|--|--|---|
| <i>date_expression</i>     | Expression that evaluates to (or is cast to) a DATE value  | Must return a DATE value   | <a href="#">Expression on page 1193</a>     |
| <i>datetime_expression</i> | Expression that evaluates to (or is cast to) a DATETIME value  | Must return a DATETIME value   | <a href="#">Expression on page 1193</a>     |
| <i>factor</i>              | Number of significant digits to replace with zero in the returned value. Default is to return the rounded or truncated integer part of the first argument. | Integer in range +32 to -32. Positive or unsigned values are applied to the right of the decimal point, and negative values are applied to the left. | <a href="#">Literal Number on page 1419</a> |
| <i>num_expression</i>      | Expression that evaluates to (or is cast to) a numeric value   | A real number  | <a href="#">Expression on page 1193</a>     |

## Usage

The **ROUND** function resembles the **TRUNC** function, whose syntax is also shown above. **ROUND** differs, however, in how it treats any portion of its first argument that is smaller than the least significant digit or time unit within the precision that its explicit or default second argument specifies.

- If the absolute value of this portion is equal to or greater than half of the smallest unit within the precision, the value of that digit or time unit is incremented by 1 in the value returned by **ROUND**. If this portion is less than half of a unit, however, it is discarded, and only the digits or time units of the first argument within the specified or default precision are returned.

That is, if the first argument is greater than zero,

- the **ROUND** function rounds down any portion of its first argument that is smaller than half a unit of the least significant digit or time unit within the precision of the second argument,
- but any portion of the first argument that is equal to or greater than half a unit is rounded up.

For example, `ROUND(3.5,0) = 4` and `ROUND(3.4,0) = 3`.

But if the first argument is less than zero,

- the **ROUND** function rounds up any portion of its first argument that is smaller than half a unit of the least significant digit or time unit within the precision of the second argument,
- but any portion of the first argument that is equal to or greater than half a unit is rounded down.

For example, `ROUND(-3.5,0) = -4` and `ROUND(-3.4,0) = -3`.

- The **TRUNC** function, in contrast, replaces with zero any digits less than the specified precision for numeric expressions. For DATE or DATETIME expressions, **TRUNC** replaces any time units smaller than the specified format string with 1 for *month* or *day* time units, or with zero for time units smaller than *day*.

The **ROUND** function can accept an optional second argument that specifies the precision of the returned value. The syntax and semantics of the second argument depend on whether the first argument is a number expression, a DATETIME expression, or DATE expression.

## Rounding numeric and MONEY values

- When the first argument is a numeric expression, the returned value is a DECIMAL and the second argument can be an integer in the range from -32 to +32 inclusive, specifying the position (relative to the decimal point) of the last significant digit of the returned value. If you omit the *factor* specification when the first argument is numeric, **ROUND** returns the integer value of the first argument rounded to a scale of zero, or to the units place. Positive-digit values specify rounding to the right of the decimal point; negative-digit values specify rounding to the left of the decimal point, as [Figure 11: Examples of negative, zero, and positive rounding factors on page 1262](#) shows:

Figure 11. Examples of negative, zero, and positive rounding factors

The following example uses the **ROUND** function with a column expression as its first argument and no second argument, so that the numeric expression is rounded to a scale of zero. This query returns the order number and rounded total price of items whose total price (rounded to the default scale of zero decimal places) is equal to \$124.00.

```
SELECT order_num , ROUND(total_price) FROM items
WHERE ROUND(total_price) = 124.00;
```

If you use a MONEY data type as the argument for the **ROUND** function and you round to an explicit or default scale of zero, the returned value is represented with `.00` as the fractional part. The SELECT statement in the following example rounds 125.46 and a MONEY column value. The query returns 125 and a rounded price in the form `xxxx.00` for each row in the **items** table.

```
SELECT ROUND(125.46), ROUND(total_price) FROM items;
```

## Rounding DATE and DATETIME values

- When the first argument to **ROUND** is a DATETIME expression, the returned value is a DATETIME YEAR TO MINUTE data type and the second argument must be a quoted string that specifies the smallest significant time unit in the returned value. If you omit the second argument, the default format string is `'DD'`, specifying the nearest day, with the hour and minute rounded to `00:00`. The following format strings are valid as the second argument:

**Table 22. Format strings for DATETIME arguments to the ROUND function**

| Format String | Effect on Returned DATETIME Value   |
|---------------|---|
| 'YEAR'        | Rounded to the beginning of the nearest year, with dates after June 30 rounded up to the next year. The <i>month</i> , <i>day</i> , <i>hour</i> , and <i>minute</i> values round to <code>-01-01 00:00</code> . |
| 'MONTH'       | Rounded to the beginning of the nearest month. Dates after the 15th are rounded up to the next month. The <i>day</i> , <i>hour</i> , and <i>minute</i> values round to <code>01 00:00</code> .                  |

| Format String | Effect on Returned DATETIME Value   |
|---------------|---|
| 'DD'          | Rounded to the beginning (00:00 = midnight) of the nearest day. DATETIME values later than 12:00 noon are rounded up to the next day.                               |
| 'DAY'         | Rounded to the beginning of the nearest Sunday. Dates that fall on Wednesday, Thursday, Friday, or Saturday are rounded up to the next Sunday.                      |
| 'HH'          | Rounded to the beginning of the nearest hour. Time of day values with <i>minute:second</i> later than 29:59 are rounded up to the next hour. Minutes round to zero. |
| 'MI'          | Rounded to the beginning of the nearest minute. Time of day values with <i>second</i> later than 30 are rounded up to the next minute.                              |

If you omit the format string specification after an initial DATETIME expression argument, the returned value is the value of the first argument rounded to the nearest day, as if you had specified 'DD' as the format string.

Examples that follow use the **ROUND** function with a column expression that returns a DATETIME YEAR TO FRACTION(5) value in a SELECT statement. In these queries, table **mytab** has only a single row, and in that row the value of **mytab.col\_dt** is 2012-12-07 14:30:12.12300.

The following query specifies 'YEAR' as the DATETIME format string:

```
SELECT ROUND(col_dt, 'YEAR') FROM mytab;
```

The value returned is 2013-01-01 00:00.

The next query resembles the previous query, but casts the returned value to a DATE data type:

```
SELECT ROUND(col_dt, 'YEAR')::DATE FROM mytab;
```

The value returned is 01/01/2013.

This example specifies 'MONTH' as the DATETIME format string:

```
SELECT ROUND(col_dt, 'MONTH') FROM mytab;
```

The value returned is 2012-12-01 00:00.

This example rounds the DATETIME expression to YEAR TO HOUR precision:

```
SELECT ROUND(col_dt, 'HH') FROM mytab;
```

The value returned is 2012-12-07 15:00.

- When the first argument is a DATE expression, the returned value is also a DATE data type if the second argument is a quoted string that specifies the smallest time unit in the returned value. These are the same format strings as for rounding DATETIME values, except that 'HH' and 'MI' are not valid for DATE values. There is no default format string for rounding DATE arguments.

To return formatted DATE values, you must specify one of the following quoted strings as the second argument to the **ROUND** function:

**Table 23. Format strings for DATE arguments to the ROUND function**

| Format String | Effect on Returned DATE Value  |
|---------------|--|
| 'YEAR'        | Rounded to the beginning of the nearest year. Dates after June 30 are rounded up to the next year. The <i>month</i> and <i>day</i> values each round to 01.  |
| 'MONTH'       | Rounded to the beginning of the nearest month. Dates after the 15th are rounded up to the next month. The returned <i>day</i> value is 01.   |
| 'DD'          | The DATE value of the first <i>date_expression</i> argument is returned.   |
| 'DAY'         | The value is rounded to the nearest Sunday. If the first argument is a Sunday, that date is returned. Dates that fall on Wednesday, Thursday, Friday, or Saturday are rounded up to the next Sunday. |

If you specify no format string as the second argument when the first argument is a DATE data type, no format string takes effect as the default. No error is issued, but the first argument is treated as numeric expression that evaluates to an integer, rather than as a DATE value. Informix® stores DATE values internally as the integer count of days since 31 December 1899. For dates in the 21st century, integer equivalents to DATE values are 5-digit integers, ranging between approximately 37,000 and 74,000.

For example, the query `SELECT ROUND(TODAY) FROM systables` provides no format string for a DATE expression, and returns the integer 40999 if the query is issued on 1 April 2012.

If you apply a numeric format specification as the second argument, nonnegative numbers have no effect on DATE values, but the following example rounds the last two digits of the returned value to zero:

```
SELECT ROUND(TODAY, -2) FROM systables;
```

On 1 April 2012, the query above would return the integer value 40900.

On the next day, 2 April 2012, the same query would return the integer value 41000.

For applications where integer-format dates like 41000 are unhelpful, you can use the 'YEAR', 'MONTH', 'DAY', or 'DD' format strings as the second argument to the **ROUND** function to prevent the DATE argument from being processed as if it were a number expression. On 1 April 2012, the following query returns the DATE value 04/01/2012 if MDY4/ is the **DBDATE** environment variable setting:

```
SELECT ROUND(TODAY, 'DD') FROM systables WHERE tabid = 1;
```

In the following example, a query is issued on Tuesday, April 3, 2012:

```
SELECT ROUND(TODAY, 'DAY') FROM mytab;
```

The returned value is 03/31/2012, the current date rounded to the nearest Sunday.

If you are using a host variable to store a rounded point-in-time value in dynamic SQL, and the data type of the first argument is not known at prepare time, Informix® assumes that a DATETIME data type is the first argument to the **ROUND** function and returns a DATETIME YEAR TO MINUTE rounded value. At execution time, after the statement is prepared, error -9750

is issued if a DATE value is supplied for the host variable. To prevent this error, you can specify the data type for the host variable by using a cast, as in this program fragment.

```
sprintf(query1, ",
  \"select round( ?::date, 'DAY') from mytab\");
EXEC SQL prepare selectq from :query;
EXEC SQL declare select_cursor cursor for selectq;
EXEC SQL open select_cursor using :hostvar_date_input;

EXEC SQL fetch select_cursor into :var_date_output;
```

For the order of precedence among the Informix® environment variables that can specify the display and data entry formats for the built-in chronological data types, see the topic [Precedence of DATE and DATETIME format specifications on page 1416](#).

## TRUNC Function

The **TRUNC** function can reduce the precision of its first numeric, DATE, or DATETIME argument by returning the truncated value. If the first argument is neither a number nor a point in time, it must be cast to a numeric, DATE, or DATETIME data type.

The **TRUNC** function can reduce the precision of its first numeric, DATE, or DATETIME argument by returning the truncated value. If the first argument is neither a number nor a point in time, it must be cast to a numeric, DATE, or DATETIME data type.

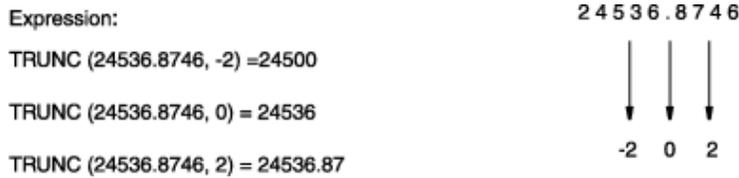

The **TRUNC** function resembles the **ROUND** function, but truncates (rather than rounds to the nearest whole number) any portion of its first argument that is smaller than the least significant digit or time unit within the precision that its second argument specifies.

- For numeric expressions, **TRUNC** replaces with zero any digits less than the specified precision.
- For DATE or DATETIME expressions, **TRUNC** replaces any time units smaller than the format specification with **1** for *month* or *day* time units, or with **0** for time units smaller than *day*.

The **TRUNC** function can accept an optional second argument that specifies the precision of the returned value.

- When the first argument is a numeric expression, the second argument must be an integer in the range from -32 to +32 inclusive, specifying the position (relative to the decimal point) of the last significant digit of the returned value. If you omit the *factor* specification when the first argument is numeric, **TRUNC** returns the value of the first argument truncated to a scale of zero, or to the units place. Positive digit values specify truncation to the right of the decimal point; negative digit values specify truncation to the left, as [Figure 12: Examples of negative, zero, and positive truncation factors on page 1266](#) shows.

Figure 12. Examples of negative, zero, and positive truncation factors

The following example calls the **TRUNC** function with a column expression that returns a numeric value in a **SELECT** statement. This statement displays the order number and truncated total price of items whose total price (truncated to the default scale of zero decimal places) is equal to \$124.00.

```
SELECT order_num , TRUNC(total_price) FROM items
WHERE TRUNC(total_price) = 124.00;
```

If a **MONEY** data type is the argument in a call to the **TRUNC** function that specifies a scale of zero, the fractional part becomes **.00** in the returned value. For example, the following **SELECT** statement truncates 125.46 and a **MONEY** column value. It returns 125 and a truncated price in the form **xxx.x00** for each row in the **items** table.

```
SELECT TRUNC(125.46), TRUNC(total_price) FROM items;
```

- When the first argument to **TRUNC** is a **DATETIME** expression, the second argument must be a quoted string that specifies the smallest significant time unit in the returned value. Only the following format strings are valid as the second argument:

**Table 24. Format strings for DATETIME arguments to the TRUNC function**

| Format String | Effect on Returned Value   |
|---------------|--|
| 'YEAR'        | Truncated to the beginning of the year. The <i>month</i> , <i>day</i> , <i>hour</i> , and <i>minute</i> values truncate to <code>01-01 00:00</code> .                    |
| 'MONTH'       | Truncated to the beginning of the first day of the month. The <i>hour</i> and <i>minute</i> values round to <code>00:00</code> .   |
| 'DD'          | Truncated to the beginning ( <code>00:00</code> = midnight) of the same day.   |
| 'DAY'         | If the first argument is a Sunday, midnight ( <code>00:00</code> ) on that date is returned. For any other day of the week, midnight on the previous Sunday is returned. |
| 'HH'          | Truncated to the beginning of the hour. The <i>minute</i> value truncates to zero.   |
| 'MI'          | Truncated to the beginning of the nearest minute. As for all of these format strings, time units smaller than <i>minute</i> are discarded.                               |

If you omit the format string specification after an initial **DATETIME** expression argument, the returned value is the value of the first argument truncated to the day, as if you had specified **'DD'** as the format string.

Examples that follow invoke the **TRUNC** function with a column expression that returns a **DATETIME YEAR TO FRACTION(5)** value in a **SELECT** statement. In these examples, table **mytab** has only a single row, and in that row the value of **mytab.col\_dt** is `2006-12-07 14:30:12.12300`.

This query specifies **'YEAR'** as the **DATETIME** format string:

```
SELECT TRUNC(col_dt, 'YEAR') FROM mytab;
```

The value returned is 2006-01-01 00:00.

The next query resembles the previous query, but casts the truncated value to a DATE data type:

```
SELECT TRUNC(col_dt, 'YEAR')::DATE FROM mytab;
```

The value returned is 01/01/2006.

This example specifies 'MONTH' as the DATETIME format string:

```
SELECT TRUNC(col_dt, 'MONTH') FROM mytab;
```

The value returned is 2006-12-01 00:00.

The following example truncates the DATETIME expression to YEAR TO HOUR precision:

```
SELECT TRUNC(col_dt, 'HH') FROM mytab;
```

The value returned is 2006-12-07 14:00.

- When the first argument is a DATE expression, the second argument should generally be a quoted string that specifies the smallest time unit in the returned value. These are the same format strings as for truncating DATETIME values, except that 'HH' and 'MI' are not valid for dates, and there is no default format string for truncating DATE expression arguments.

To return formatted DATE values, you must use one of the following quoted strings as the second argument to the **TRUNC** function:

**Table 25. Format strings for DATE arguments to the TRUNC function**

| Format String | Effect on Returned Value  |
|---------------|---|
| 'YEAR'        | Truncated to the beginning of the year. The <i>month</i> and <i>day</i> values are each 01.   |
| 'MONTH'       | Truncated to the beginning of the month. The <i>day</i> value is 01.  |
| 'DD'          | The DATE value of the first <i>date_expression</i> argument is returned.  |
| 'DAY'         | If the first argument is a Sunday, that date is returned. For any other day of the week, the date of the previous Sunday is returned. |

If you specify no format string as the second argument when the first argument is a DATE data type, no format string takes effect as the default. No error is issued, but the first argument is treated as numeric expression that evaluates to an integer, rather than as a DATE value. Informix® stores DATE values internally as the integer count of days since 31 December 1899.

For example, the query `SELECT ROUND(TODAY) FROM systables` provides no format string for a DATE expression, and returns the integer 39538 if the query is issued on 1 April 2008.

If you apply a numeric format specification as the second argument, nonnegative numbers have no effect on DATE values, but the following example rounds the last two digits of the returned value to zero:

```
SELECT TRUNC(TODAY, -2) FROM systables;
```

For applications where integer dates like 39500 are unhelpful, use the 'YEAR', 'MONTH', 'DAY', or 'DD' format strings as the second argument to the **TRUNC** function, to prevent the DATE expression from being processed as if it were a number

expression. On 1 April 2008, the following query returns the DATE value 04/01/2008 if MDY4/ is the setting of the **DBDATE** environment variable:

```
SELECT TRUNC(TODAY, 'DD') FROM systables;
```

If you are using a host variable to store a truncated point-in-time value in dynamic SQL, and the data type of the first argument is not known at prepare time, Informix® assumes that a DATETIME data type is the first argument to the **TRUNC** function and returns a DATETIME YEAR TO MINUTE truncated value. At execution time, after the statement is prepared, error -9750 is issued if a DATE value is supplied for the host variable. To prevent this error, you can specify the data type for the host variable by using a cast, as in this program fragment.

```
sprintf(query2, "%s",
  "select trunc( ?::date, 'DAY') from mytab");
EXEC SQL prepare selectq from :query2;
EXEC SQL declare select_cursor cursor for selectq;
EXEC SQL open select_cursor using :hostvar_date_input;

EXEC SQL fetch select_cursor into :var_date_output;
```

For the order of precedence among the Informix® environment variables that can specify the display and data entry formats for the built-in chronological data types, see the topic [Precedence of DATE and DATETIME format specifications on page 1416](#).

Note that the **TRUNC** function name is based on a use of the English word "truncate" that is different from its meaning in the TRUNCATE statement of SQL. The **TRUNC** function replaces the value of its first argument with another value that has a smaller precision or the same precision. The TRUNCATE statement deletes all of the rows from a database table, without dropping the table schema.

## Bitshift Functions

Bitshift functions perform a bit shift operation on an integer or bigint value and return the shift result.

The bitshift functions have the following syntax.

```
|---IFX_BIT_LEFTSHIFT---|--operand--,--amount---|
'--IFX_BIT_RIGHTSHIFT--'
```

| Element        | Description  | Restrictions  | Syntax                                  |
|----------------|--|---|---|
| <i>operand</i> | Entity whose bits are to be shifted. Its type will also be function's return type. | Must be of type integer or bigint.  | <a href="#">Expression on page 1193</a> |
| <i>amount</i>  | Number of bits operand will be shifted by.   | Integer value between 0 and number of bits in operand's type (or respective modulo of any other integer value). | <a href="#">Expression on page 1193</a> |

## IFX\_BIT\_LEFTSHIFT Function

The **IFX\_BIT\_LEFTSHIFT** function performs a bit left shift operation on an integer or bigint value and returns the shift result

The **IFX\_BIT\_LEFTSHIFT** function performs a bit left shift operation on an integer or bigint value and returns the shift result. It takes as arguments an integer or bigint operand and an integer operator. The type of the operand will be the function's return type. The operator determines the number of bits by which the passed in value gets shifted to the left, its value should range between 0 and 31 for integer operands, and between 0 and 63 for bigint operands (any other values might be taken as their modulo of 32 or 64 respectively, but that's not guaranteed).

The effect of `ifx_bit_leftshift` is equivalent to multiplying the operand by 2 to the power of operator, but is of course limited to the resulting type's capacity.

With both integer and bigint, the value with only the high bit set carries special meaning as it signifies a NULL value. Should the bit shift result in an integer 0x80000000, you'd receive error 1215, whereas a bigint result 0x8000000000000000 would be returned as NULL.

Examples:

| operand          | operator | result     |              |
|------------------|----------|------------|--------------|
| 1                | 4        | 16         | (0x00000010) |
| 3                | 2        | 12         | (0x0000000c) |
| "0x800"::integer | 5        | 65536      | (0x00010000) |
| 12345            | 26       | -469762048 | (0xe4000000) |
| 1                | 31       | error 1215 |              |
| 1::bigint        | 31       | 2147483648 | (0x80000000) |

## IFX\_BIT\_RIGHTSHIFT Function

The **IFX\_BIT\_RIGHTSHIFT** function performs a bit right shift operation on an integer or bigint value and returns the shift result.

The **IFX\_BIT\_RIGHTSHIFT** function performs a bit right shift operation on an integer or bigint value and returns the shift result. It takes as arguments an integer or bigint operand and an integer operator. The type of the operand will be the function's return type. The operator determines the number of bits by which the passed in value gets shifted to the right, its value should range between 0 and 31 for integer operands, and between 0 and 63 for bigint operands (any other values might be taken as their modulo of 32 or 64 respectively, but that's not guaranteed).

Example:

```
select name, IFX_BIT_RIGHTSHIFT(partnum, 20) as dbspace_num
from sysmaster:sysdatabases;
```

## CARDINALITY Function

The **CARDINALITY** function returns the number of elements in a collection column (SET, MULTISSET, LIST).

The **CARDINALITY** function has the following syntax.

CARDINALITY Function

**CARDINALITY**

```
(
  collection_col collection_var
)
```

| Element               | Description                         | Restrictions                               | Syntax                                  |
|-----------------------|-------------------------------------|--|---|
| <i>collection_col</i> | An existing collection column       | Must be declared as a collection data type | <a href="#">Identifier on page 1456</a> |
| <i>collection_var</i> | Host or program collection variable | Must be declared as a collection data type | Language specific                       |

Suppose that the **set\_col** SET column contains the following value:

```
{3, 7, 9, 16, 0}
```

The following SELECT statement returns 5 as the number of elements in the **set\_col** column:

```
SELECT CARDINALITY(set_col)
FROM table1;
```

If the collection contains duplicate elements, **CARDINALITY** counts each individual element.

## SQLCODE Function (SPL)

The **SQLCODE** function takes no arguments, but returns to its calling context the value of **sqlca.sqlcode** for the most recently executed SQL statement (whether static or dynamic) that the current SPL routine has executed. Only use **SQLCODE** in the context of a cursor.

SQLCODE

**SQLCODE**

You can use **SQLCODE** in expressions within SPL routines to identify the state of a dynamic cursor. This built-in function is useful in error handling and in contexts such as determining whether a query or function call has returned no rows, or when a cursor has reached the last row of the active set, or to identify other conditions when SPL program control should exit from a loop.

The following SPL program fragment illustrates the use of **SQLCODE** to detect the end of the active set of a cursor within a WHILE loop.

**Example**

```
CREATE PROCEDURE ...
...
DEFINE myc1 ...
...
```

```

PREPARE p FOR "SELECT c1 FROM t1";
DECLARE cur FROM s;
OPEN cur;

FETCH cur INTO myc1;
WHILE (SQLCODE != 100)
FETCH cur INTO myc1;
    -- process myc1
...
END WHILE;

END PROCEDURE;

```

The **SQLCODE** function is not needed in UDRs written in ESQL/C, which have direct access to the SQL Communications Area (**SQLCA**) through the GET DIAGNOSTICS statement of Dynamic SQL and by other mechanisms. The database server issues an error if the calling context of the built-in **SQLCODE** function is not an SPL routine.

## DBINFO Function

The following diagram shows the syntax of the **DBINFO** function.

DBINFO Function

### DBINFO

```

(
'dbpace',
tblspace_num expression
'sqlca.sqlerrd1' 'sqlca.sqlerrd2'
593
'sessionid'
'cdrsession'
'dbname'
'dbhostname'
'serial8'
'bigserial'
'get_tz'
'utc_current'
'utc_to_datetime',
utc_value table.column
'version',parameter'
)

```

| Element       | Description                          | Restrictions               | Syntax                                  |
|---------------|--------------------------------------|----------------------------|---|
| <i>column</i> | Name of a column in the <i>table</i> | Must exist in <i>table</i> | <a href="#">Identifier on page 1456</a> |

593. Informix® extension

| Element             | Description   | Restrictions  | Syntax   |
|---------------------|---|---|--|
| <i>expression</i>   | Expression that evaluates to <i>tblspace_num</i>  | Can contain column names, SPL variables, host variables, or subqueries, but must return a numeric value | <a href="#">Expression on page 1193</a>  |
| <i>parameter</i>    | Quoted string that specifies which part of the <i>version</i> string to return                    | For valid <i>parameter</i> values, see <a href="#">Using the 'version' Option on page 1277</a>          | See the <b>Restrictions</b> column.  |
| <i>table</i>        | Table for which to display the dbspace name or containing an integer <i>column</i> of UTC values. | Must match the name of a table in the FROM clause of the query  | <a href="#">Identifier on page 1456</a>  |
| <i>tblspace_num</i> | Tblspace number (partition number) of a table   | Must exist in the <b>partnum</b> column of the <b>systables</b> table for the database                  | <a href="#">Literal Number on page 1419</a>  |
| <i>utc_value</i>    | A UTC value to be converted to the DATETIME equivalent  | Must be a numeric expression that evaluates to the number of seconds since 1970-01-01 00:00:00+00:00    | <a href="#">Expression on page 1193</a> ,<br><a href="#">Literal Number on page 1419</a> |

## DBINFO Options

The **DBINFO** function is actually a set of functions that return different types of information about the database. To invoke each function, specify its option as the quoted-string argument after the **DBINFO** keyword. You can use any **DBINFO** option anywhere within SQL statements and within UDRs.

The following table shows the categories of database and database server information that Informix® can retrieve with valid **DBINFO** options.

- The **Arguments** column shows the parentheses-delimited argument list of each valid **DBINFO** option.
- The **Information Returned** column shows the type of database information that the **Arguments** option retrieves.
- The **Topic** column shows where you can find more information about the **Arguments** option.

| Arguments                        | Information Returned  | Topic  |
|----------------------------------|---|--|
| ('dbhostname')                   | The host name of the database server to which a client application is connected     | <a href="#">Using the 'dbhostname' Option on page 1277</a>                     |
| ('dbname')                       | The identifier of the database to which a client application is connected           | <a href="#">Using the 'dbname' Option on page 1276</a>                         |
| ('dbspace' <i>tblspace_num</i> ) | The name of a dbspace corresponding to a <i>tblspace</i> number                     | <a href="#">Using the ('dbspace', <i>tblspace_num</i>) Option on page 1273</a> |
| ('get_tz')                       | The time zone of the session, <b>\$TZ</b> , as specified as a string by the client. | <a href="#">Using the 'get_tz' Option on page 1279</a>                         |

| Arguments                                    | Information Returned   | Topic  |
|--|--|--|
| ('serial8')                                  | The last SERIAL8 value inserted in a table   | <a href="#">Using the 'serial8' and 'bigserial' options on page 1278</a> |
| ('bigserial')                                | The last BIGSERIAL value inserted in a table   | <a href="#">Using the 'serial8' and 'bigserial' options on page 1278</a> |
| ('sessionid')                                | The session ID number of the current session   | <a href="#">Using the 'sessionid' Option on page 1275</a>                |
| ('cdrsession')                               | Whether a thread is performing an Enterprise Replication operation   | <a href="#">Using the 'cdrsession' option on page 1276</a>               |
| ('sqlca.sqlerrd1')                           | The last SERIAL value inserted in a table  | <a href="#">Using the 'sqlca.sqlerrd1' Option on page 1274</a>           |
| ('sqlca.sqlerrd2')                           | The number of rows processed by SELECT, INSERT, DELETE, UPDATE, EXECUTE PROCEDURE, and EXECUTE FUNCTION statements   | <a href="#">Using the 'sqlca.sqlerrd2' Option on page 1274</a>           |
| ('utc_current')                              | The current UTC time value (as an integer number of seconds since 1970-01-01 00:00:00+00:00) when the SQL statement began to execute.  | <a href="#">Using the 'utc_current' Option on page 1279</a>              |
| ('utc_to_datetime',<br><i>table.column</i> ) | The DATETIME value corresponding to a specified integer column containing a UTC time value (as an integer number of seconds since 1970-01-01 00:00:00+00:00).  | <a href="#">Using the 'utc_to_datetime' Option on page 1280</a>          |
| ('utc_to_datetime', <i>utc_value</i> )       | The DATETIME value corresponding to a specified UTC time value (as an integer number of seconds since 1970-01-01 00:00:00+00:00).  | <a href="#">Using the 'utc_to_datetime' Option on page 1280</a>          |
| ('version', ' <i>parameter</i> ')            | Type of the database server and its release version to which the client application is connected. (The call to <b>DBINFO</b> fails with an error if no <i>parameter</i> specifies a format for the version information.) | <a href="#">Using the 'version' Option on page 1277</a>                  |

## Using the ('dbspace', tblspace\_num) Option

The **'dbspace'** option returns a character string that contains the name of the dbspace that corresponds to a tblspace number. You must supply an additional parameter, either *tblspace\_num* or an expression that evaluates to *tblspace\_num*. The following example uses the **'dbspace'** option. First, it queries the **systables** system catalog table to determine the *tblspace\_num* for the table *customer*, then it executes the function to determine the *dbspace* name.

```
SELECT tabname, partnum FROM systables
where tabname = 'customer';
```

If the query returns a partition number of 1048892, you insert that value into the second argument to find which dbspace contains the **customer** table, as the following example shows:

```
SELECT DBINFO ('dbspace', 1048892) FROM systables
where tabname = 'customer';
```

If the table for which you want to know the dbspace name is fragmented, you must query the **sysfragments** system catalog table to find out the tblspace number of each table fragment. Then you must supply each tblspace number in a separate **DBINFO** query to find out all the dbspaces across which a table is fragmented.

## Using the 'sqlca.sqlerrd1' Option

The **'sqlca.sqlerrd1'** option returns a single integer that provides the last serial value that is inserted into a table. To ensure valid results, use this option immediately following a singleton INSERT statement that inserts a single row with a serial value into a table.

**Tip:** To obtain the value of the last SERIAL8 value that is inserted into a table, use the **'serial8'** option of DBINFO. For more information, see [Using the 'serial8' and 'bigserial' options on page 1278](#).

The following example uses the **'sqlca.sqlerrd1'** option:

```
EXEC SQL create table fst_tab (ordernum serial, partnum int);
EXEC SQL create table sec_tab (ordernum serial);
EXEC SQL insert into fst_tab VALUES (0,1);
EXEC SQL insert into fst_tab VALUES (0,4);
EXEC SQL insert into fst_tab VALUES (0,6);
EXEC SQL insert into sec_tab values (dbinfo('sqlca.sqlerrd1'));
```

This example inserts a row that contains a primary-key serial value into the **fst\_tab** table, and then uses the DBINFO function to insert the same serial value into the **sec\_tab** table. The value that the DBINFO function returns is the serial value of the last row that is inserted into **fst\_tab**.

Because the SQLCA structure does not record serial values that are inserted by triggers, you cannot call the DBINFO function with the **'sqlca.sqlerrd1'**, **'bigserial'**, or **'serial8'** options to return a serial value that a triggered action inserts.

For more information about the SQL Communications Area (SQLCA) data structure, within which **sqlca.sqlerrd1** is a field, see the *Informix® Guide to SQL: Tutorial*.

## Using the 'sqlca.sqlerrd2' Option

The **'sqlca.sqlerrd2'** option returns a single integer that provides the number of rows that SELECT, INSERT, DELETE, UPDATE, EXECUTE PROCEDURE, and EXECUTE FUNCTION statements processed. To ensure valid results, use this option after SELECT, EXECUTE PROCEDURE, and EXECUTE FUNCTION statements have completed executing. In addition, to ensure valid results when you use this option within cursors, make sure that all rows are fetched before the cursors are closed.

The following example shows an SPL routine that uses the **'sqlca.sqlerrd2'** option to determine the number of rows that are deleted from a table:

```
CREATE FUNCTION del_rows (pnumb INT)
RETURNING INT;

DEFINE nrows INT;

DELETE FROM fst_tab WHERE part_number = pnumb;
LET nrows = DBINFO('sqlca.sqlerrd2');
RETURN nrows;

END FUNCTION;
```

For more information about the SQL Communications Area (SQLCA) data structure, within which **sqlca.sqlerrd2** is a field, see the *Informix® Guide to SQL: Tutorial*.

## Using the 'sessionid' Option

The **'sessionid'** option of the **DBINFO** function returns the session ID of your current session. When a client application makes a connection to the database server, the database server starts a session with the client and assigns a session ID for the client. The session ID serves as a unique identifier for a given connection between a client and a database server.

The database server stores the value of the session ID in a data structure in shared memory that is called the *session control block*. The session control block for a given session also includes the user ID, the process ID of the client, the name of the host computer, and a variety of status flags.

When you specify the **'sessionid'** option, the database server retrieves the session ID of your current session from the session control block and returns this value to you as an integer. Some of the System-Monitoring Interface (SMI) tables in the **sysmaster** database include a column for session IDs, so you can use the session ID that the **DBINFO** function obtained to extract information about your own session from these SMI tables. For further information on the session control block, see the *Informix® Administrator's Guide*. For further information on the **sysmaster** database and the SMI tables, see the .

In the following example, the user specifies the **DBINFO** function in a SELECT statement to obtain the value of the current session ID. The user poses this query against the **systables** system catalog table and uses a WHERE clause to limit the query result to a single row.

```
SELECT DBINFO('sessionid') AS my_sessionid
FROM systables
WHERE tabname = 'systables';
```

In the preceding example, the SELECT statement queries against the **systables** system catalog table. You can, however, obtain the session ID of the current session by querying against any system catalog table or user table in the database. For example, you can enter the following query to obtain the session ID of your current session:

```
SELECT DBINFO('sessionid') AS user_sessionid
FROM customer
WHERE customer_num = 101;
```

You can use the **DBINFO** 'sessionid' option not only in SQL statements but also in SPL routines. The following example shows an SPL function that returns the value of the current session ID to the calling program or routine:

```
CREATE FUNCTION get_sess()
RETURNING INT;
RETURN DBINFO('sessionid');
END FUNCTION;
```

## Using the 'cdrsession' option

The 'cdrsession' option to the DBINFO() function detects if an INSERT, UPDATE, or DELETE statement is being performed as part of a replicated transaction.

You might want to design triggers, stored procedures, or user-defined routines to take different actions depending on whether a transaction is being performed as part of Enterprise Replication. The 'cdrsession' option of the DBINFO() function returns 1 if the thread performing the database operation is an Enterprise Replication apply or sync thread; otherwise, the function returns 0.

The following example shows an SPL function that uses the 'cdrsession' option to determine if a thread is performing an Enterprise Replication operation:

```
CREATE FUNCTION iscdr ()
RETURNING int;

DEFINE iscdrthread int;
SELECT DBINFO('cdrsession') into iscdrthread
from systables where tabid = 1;
RETURN iscdrthread;

END FUNCTION
```

## Using the 'dbname' Option

You can use the **'dbname'** option to retrieve the name of the current database. This option returns the identifier of the database to which the client session is currently connected.

In the following example, the user enters the **'dbname'** option of **DBINFO** in a SELECT statement to retrieve the name of the database to which DB-Access is connected:

```
SELECT DBINFO('dbname')
FROM systables
WHERE tabid = 1;
```

The following table shows the result of this query.

| (constant)  |
|-------------|
| stores_demo |

## Using the 'dbhostname' Option

You can use the **'dbhostname'** option to retrieve the host name of the database server to which a database client is connected.

This option retrieves the physical computer name of the computer on which the database server is running.

In the following example, the user enters the **'dbhostname'** option of **DBINFO** in a SELECT statement to retrieve the host name of the database server to which DB-Access is connected:

```
SELECT DBINFO('dbhostname')
FROM systables
WHERE tabid = 1;
```

The following table shows the result of this query.

| (constant) |
|------------|
| rd_lab1    |

## Using the 'version' Option

You can use the **'version'** option of the **DBINFO** function to retrieve information from the message log about the type and release version of the database server against which the client application is running.

You must include a *'parameter'* specification after the **'version'** option to indicate which part of the version string you want to retrieve.

If after **'version'** you specify **'full'** as the *parameter* value, **DBINFO** returns the complete version string, which is the same value that the **-V** option of the **oninit** utility displays. The following table lists all the valid *parameter* arguments to **DBINFO** that can retrieve version information about the database server:

- The **Arguments** column shows the parentheses-delimited argument list of each valid **DBINFO ('version', 'parameter')** combination.
- The **Part of Version String Returned** column shows which part of the version string each **Arguments** list returns.
- The **Example of Returned Value** column shows gives an example of what is returned by each value of *parameter* for the **Arguments** option.

Each example returns part of the complete version string Informix® `Version 11.50.UC6.`

| Arguments                  | Part of Version String Returned   | Example of Returned Value   |
|----------------------------|---|-----------------------------|
| ('version', 'server-type') | Type of database server   | Informix                    |
| ('version', 'major')       | Major version number of the current database server version   | 11                          |
| ('version', 'minor')       | Minor version number of the current database server version   | 50                          |
| ('version', 'os')          | Operating-system identifier within the version string:  | U                           |
|                            | T = 32-bit Windows™ platforms<br>U = UNIX™ 32-bit running on a 32-bit operating system<br>H = UNIX™ 32-bit running on a 64-bit operating system<br>F = All 64-bit platforms |                             |
| ('version', 'level')       | Interim release level of the current database server version  | C6                          |
| ('version', 'full')        | Complete version string as it would be returned by <b>oninit -V</b>   | Informix, Version 11.50.UC6 |

**Important:** Not all UNIX™ environments fit the word-length descriptions of operating-system (os) codes in the preceding table. For example, some **U** versions can run on 64-bit operating systems. Similarly, some **F** versions can run on operating systems with 32-bit kernels that support 64-bit applications.

The following example shows how to use the **'version'** option of **DBINFO** in a SELECT statement to retrieve the major version number of the database server that the DB-Access client is connected to:

```
SELECT DBINFO('version', 'major')
FROM systables
WHERE tabid = 1;
```

The following table shows the result of this query.

| (constant) |
|------------|
| 7          |

## Using the 'serial8' and 'bigserial' options

The 'bigserial' and 'serial8' options respectively return a single integer that specifies the last SERIAL8 or BIGSERIAL value that was inserted into a table. To ensure valid results, use this option immediately following an INSERT statement that inserts a SERIAL8 or BIGSERIAL value.

**Tip:** To obtain the value of the last SERIAL value that is inserted into a table, use the 'sqlca.sqlerrd1' option of DBINFO(.). For more information, see [Using the 'sqlca.sqlerrd1' Option on page 1274](#).

The following example uses the 'serial8' option:

```
EXEC SQL CREATE TABLE fst_tab
  (ordernum SERIAL8, partnum INT);
EXEC SQL CREATE TABLE sec_tab (ordernum SERIAL8);

EXEC SQL INSERT INTO fst_tab VALUES (0,1);
EXEC SQL INSERT INTO fst_tab VALUES (0,4);
EXEC SQL INSERT INTO fst_tab VALUES (0,6);

EXEC SQL INSERT INTO sec_tab
  SELECT dbinfo('serial8')
  FROM fst_tab WHERE partnum = 6;
```

This example inserts a row that contains a primary-key SERIAL8 value into the **fst\_tab** table and then uses the DBINFO function to insert the same SERIAL8 value into the **sec\_tab** table. The value that the DBINFO function returns is the SERIAL8 value of the last row that is inserted into **fst\_tab**. The subquery in the last line contains a WHERE clause so that a single value is returned.

The SQLCA structure does not record serial values that are inserted by triggers. You cannot call the DBINFO function with the 'bigserial' option to return the most recent BIGSERIAL value that was inserted directly by the triggered action of a trigger on a table (nor of an INSTEAD OF trigger on a view). For the same reason, the DBINFO ('serial8') function cannot return a SERIAL8 value that was inserted by a trigger on a table, nor by an INSTEAD OF trigger on a view.

## Using the 'get\_tz' Option

The **'get\_tz'** option returns the \$TZ string that shows the time zone of the current session.

The following example uses the **'get\_tz'** option in a query of the **cust\_calls** table of the **stores\_demo** database:

```
EXEC SQL select first call_dtime, dbinfo('get_tz')
  from cust_calls where customer_num = 106;
```

This example returns a string value of the session time zone and the first **call\_dtime** value in the **cust\_calls** table for which the **customer\_num** value is 106.

## Using the 'utc\_current' Option

The **'utc\_current'** option returns the current value of Coordinated Universal Time (UTC) as an integer value that shows the number of seconds that have elapsed between 1970-01-01 00:00:00+00:00) and when the current SQL statement began to execute.

Unlike Universal Time (UT), which calculates the duration of seconds from the earth's rotation, UTC uses seconds of a fixed length, based on high-precision atomic clocks.

Because of variation in the earth's gradually diminishing rotation rate, intercalary *leap seconds* are introduced from time to time in UTC to reduce discrepancies with UT time. By default, Informix® ignores leap seconds in DATETIME and INTERVAL arithmetic. When Informix® is supported by an operating system that takes leap seconds into account, however, the leap seconds are reflected in subsequent DATETIME and INTERVAL operations after the operating system adjusts the system clock for leap seconds.

## Using the 'utc\_to\_datetime' Option

The 'utc\_to\_datetime' option of the DBINFO function returns the UTC seconds to DATETIME value that the server would generate if the UNIX™ time( ) system call returned the value of the second parameter, taking into account the time zone of the database server.

The 'utc\_to\_datetime' option casts to a DATETIME value its last argument, which must be a numeric expression representing a Coordinated Universal Time (UTC) value. If this evaluates to a number with a fractional part, any fractional seconds are ignored.

In the first example below, the last argument is a UTC value represented as a literal integer. In the second example, the last argument is a column expression specifying an integer column that stores UTC values. In both examples, DBINFO casts the UTC value to a DATETIME value in the time zone of the database server:

```
DBINFO ('utc_to_datetime', 1299912999 )
DBINFO ('utc_to_datetime', timesheet.utc_checkin )
```

If the value of the last argument is negative, the function returns a DATETIME value from an earlier UNIX™ epoch, as in the next example:

```
SELECT DBINFO("utc_to_datetime", -2134567890.91234)
FROM 'sysmaster:"informix".sysdual';
```

This query returns the DATETIME value 1902-05-12 08:28:30.

These example times all assume that the server is in a specific time zone. The following query returns four DATETIME values:

```
SELECT
  DBINFO('utc_to_datetime', -32767) AS min_smallint,
  DBINFO('utc_to_datetime', +32767) AS max_smallint,
  DBINFO('utc_to_datetime', 1299912999),
  DBINFO("utc_to_datetime", -2134567890.91234)
FROM 'sysmaster:"informix".sysdual';
```

These are the returned DATETIME values from a server in the United States Pacific time zone:

```
1969-12-31 06:53:53   1970-01-01 01:06:07   2011-03-11 22:56:39
1902-05-12 01:28:30
# Server running in TZ=US/Pacific
```

These are the returned DATETIME values from the same query from a server in the UTC0 time zone:

```
1969-12-31 14:53:53   1970-01-01 09:06:07   2011-03-12 06:56:39
1902-05-12 08:28:30
# Server running in TZ=UTC0
```

Note that the DAY component in the third DBINFO result is different for the United States Pacific time zone and for the UTC0 time zone, because of the 8-hour offset between those two time zones.

The database server time zone can similarly affect the return value from other expressions for points in time, such as `CURRENT`, `SYSDATE`, and `TODAY`, whose `DATETIME YEAR TO SECOND` or `DATE` representation depends on the time zone of the server.

## Encryption and decryption functions

Informix® supports built-in encryption and decryption functions.

The encryption functions **ENCRYPT\_AES** and **ENCRYPT\_TDES** return an *encrypted\_data* value that encrypts the *data* argument. Conversely, decryption functions **DECRYPT\_CHAR** and **DECRYPT\_BINARY** return a plain-text *data* value from the *encrypted\_data* argument. Use this syntax to call these functions:

Encryption and Decryption Functions

### **ENCRYPT\_AES ENCRYPT\_TDES**

```
(data
, password
, hint
)
```

### **DECRYPT\_CHAR DECRYPT\_BINARY**

```
(encrypted_data
, password
)
```

**GETHINT**( *encrypted\_data* )

| Element               | Description  | Restrictions                                 | Syntax                                     |
|-----------------------|--|--|--|
| <i>data</i>           | A plain text character string, variable, or large object of type BLOB or CLOB to be encrypted  | Must be a character or BLOB data type        | <a href="#">Expression on page 1193</a>    |
| <i>encrypted_data</i> | A character string or variable containing output from <b>ENCRYPT_AES</b> or from <b>ENCRYPT_TDES</b>   | Decryption requires the encryption password  | <a href="#">Expression on page 1193</a>    |
| <i>hint</i>           | A character string that you define here. Default is the value from the WITH HINT clause of the SET ENCRYPTION statement that defined <i>password</i> . | No more than 32 bytes                        | <a href="#">Quoted String on page 1424</a> |
| <i>password</i>       | A character string that the encryption function defines. Default is the session password value defined by the SET ENCRYPTION statement                 | At least 6 bytes, but no more than 128 bytes | <a href="#">Quoted String on page 1424</a> |

You can invoke these encryption and decryption functions from within DML statements or with the EXECUTE FUNCTION statement.

For distributed operations over a network, all participating database servers must support these (or equivalent) functions. If the network is not secure, the DBSA must enable the *encryption communication support module* (ENCCSM) to provide data encryption between the database server and client systems, in order to avoid transmitting passwords as plain text.

Encryption or decryption calls slow the performance of the SQL statement within which these functions are invoked, but have no effect on other statements. However, if you store encrypted data in a column that is an index key, or in a column on which a constraint is defined, Informix® cannot enforce the constraint, and DML statements cannot use the index.

Similarly, do not encrypt a column whose value is referenced in the fragment key expression of a fragmented table.

You cannot encrypt the security label in a column of type IDSSECURITY label.

## Column Level and Cell Level Encryption

The encryption and decryption functions can support two ways of using data encryption features, namely *column level* and *cell level* encryption.

- Column level encryption means that all values in a given column are encrypted with the same password (which can be a word or phrase), the same cipher, and the same cipher mode.

Users of this form of encryption should consider not using the *hint* feature of these functions, but instead store a mnemonic hint for remembering the password in some other location. Otherwise, the same *hint* will occupy disk space in every row that contains an encrypted value.

- Cell level encryption means that within a column of encrypted data many different passwords (or different ciphers or cipher modes) are used.

This use of encryption is also called *row-column level* or *set-column level* encryption. Compared to column-level encryption, this makes the task of data management more complex, because if different passwords are required for decrypting different rows of the same table, it is not possible to write a single SELECT statement to fetch all the decrypted data. In some situations, however, individual users may need this technique to protect personal data.

To protect data security and confidentiality, the database server does not store information in the system catalog to indicate whether any table (or any column or row) includes encrypted data. Similarly, the logical logs of Informix® do not record SET ENCRYPTION statements, nor calls to encryption or decryption functions. (The Trusted Facility feature for secure auditing, however, can use the 'STEP' audit-event mnemonic to record execution of the SET ENCRYPTION statement, and can use the 'CRPT' audit-event mnemonic to record successful or unsuccessful calls to **DECRYPT\_CHAR** or **DECRYPT\_BINARY**.)

## The Password and Hint Specifications

The SET ENCRYPTION statement or an encryption function can define a password and hint for the current session. The *password* must be specified as a character expression that returns at least 6 bytes, but no more than 128. The optional *hint* is specified as a character expression that returns no more than 32 bytes.

The purpose of the *hint* is to help users to remember the *password*. When you call **ENCRYPT\_AES** or **ENCRYPT\_TDES** with a *hint* argument, it is encrypted and embedded in the *encrypted\_data*, from which **GETHINT** can retrieve it. But if you define *hint* as NULL, or omit *hint* when SET ENCRYPTION specified no default *hint* for the *session password*, no *hint* is embedded in the *encrypted\_data*.

The *password* used for encryption and decryption is either the *password* argument to the function, or if you omit this argument, it is the *session password* specified in the last SET ENCRYPTION statement executed before you invoke the function.

The **DECRYPT\_CHAR**, **DECRYPT\_BINARY**, or **GETHINT** function call fails with an error if the *encrypted\_data* argument is not in an encrypted format, or if the *password* argument to a decryption function is omitted when no *session password* value was set by SET ENCRYPTION. An error also results if the *password* used for decryption is not the same *password* used for encryption.

Encryption key management, which is critical to the secure operation of the database, is delegated entirely to the application. This implementation means that the *password* itself is not stored in the database. Without help from the user through the application, the database server cannot decrypt the encrypted data.

If you invoke any of these functions from a UDR, you might prefer to set a *session password* in the SET ENCRYPTION statement. Otherwise, *password* will be visible to users who can view the **sysprocbody.data** column in the system catalog.

## Data Types, Encoding, and Size of Encrypted Values

The *data* and corresponding *encrypted\_data* arguments can be of any built-in character type (CHAR, LVARCHAR, NCHAR, NVARCHAR, or VARCHAR), or can be a smart large object of type BLOB or CLOB. (Use CLOB in place of TEXT, which these functions do not support.)

Corresponding *data* and *encrypted\_data* values that the encryption or decryption functions return have the same character, BLOB, or CLOB data type, except in cases where encryption of a VARCHAR or NVARCHAR string would return an overflow error. For operations on CHAR, LVARCHAR, NCHAR, NVARCHAR, or VARCHAR data and on *encrypted\_data* values, the encryption and decryption functions follow the data-type promotion rules of **CONCAT** and the other SQL string manipulation functions for the data type of their return value, as in the following examples.

- If the VARCHAR *data* argument to **ENCRYPT\_TDES** (with no hint) is a 200 byte string, then Informix® automatically promotes the returned value to an LVARCHAR data type, because the encrypted value exceeds the 255 byte limit for VARCHAR objects.
- If the NVARCHAR *encrypted\_data* argument to **ENCRYPT\_AES** (with a hint) is a string 200 bytes long, then Informix® automatically promotes the returned value to an NCHAR data type, because the encrypted value exceeds the 255 byte limit for NVARCHAR objects.

For more information about return type promotion for character strings that the encryption, decryption, and certain other string-manipulation functions return, see [Return Types from the CONCAT Function on page 1328](#). The first table in that section describes *data* or *encrypted\_data* arguments that are not smart large objects. (For smart large object arguments, the return type is a BLOB or CLOB object.)

The encryption or decryption function call returns overflow error -881, however, if the return value exceeds the 32,767-byte limit for CHAR, NCHAR strings, or the 32,739-byte limit for LVARCHAR strings. To avoid this error, use BLOB or CLOB objects as the *data* or *encrypted\_data* argument, rather than a character data type, when the encryption or decryption operation requires an argument or a return value that might be larger than the (approximately 32Kb) limit for character data types.

Except for original *data* of BLOB or CLOB data types, the *encrypted\_data* value is encoded in BASE64 format. An encrypted value requires more space than the corresponding plain text, because the database must also store the information (except for the encryption key) that is needed for decryption. If a *hint* is used, it adds to the length of *encrypted\_data*.

The BASE64 encoding scheme stores 6 bits of input data as 8 bits of output. To encode N bytes of data, BASE64 requires at least  $((4N+3)/3)$  bytes of storage, where the slash character ( / ) represents integer division. Padding and headers can increase BASE64 storage requirements above this  $((4N+3)/3)$  ratio. [Example of Column Level Encryption on page 1284](#) lists formulae to estimate the size of data values encrypted in BASE64 format. It typically requires changes to the schema of an existing table that will store BASE64 format encrypted data, especially if a hint will also be stored.

The following table shows how the data type of the input string corresponds to the data type of the value that **ENCRYPT\_AES** or **ENCRYPT\_TDES** returns:

**Table 26. Data Types for ENCRYPT\_AES and ENCRYPT\_TDES Functions**

| Plain Text Data Type | Encrypted Data Type | Decryption Function |
|----------------------|---------------------|---------------------|
| CHAR                 | CHAR                | DECRYPT_CHAR        |
| NCHAR                | NCHAR               | DECRYPT_CHAR        |
| VARCHAR              | VARCHAR or CHAR     | DECRYPT_CHAR        |
| NVARCHAR             | NVARCHAR or NCHAR   | DECRYPT_CHAR        |
| LVARCHAR             | LVARCHAR            | DECRYPT_CHAR        |
| BLOB                 | BLOB                | DECRYPT_BINARY      |
| CLOB                 | BLOB                | DECRYPT_CHAR        |

Columns of type VARCHAR and NVARCHAR store no more than 255 bytes. If the *data* string is too long for these data types to store both the encrypted data and encryption overhead, then the value returned by the encryption function is automatically changed from VARCHAR or NVARCHAR into a fixed CHAR or NCHAR value, with no trailing blanks in the encoded encrypted value.

Encrypted values of type BLOB or CLOB are not in BASE64 encoding format, and their size increase after encryption is independent of the original data size. For BLOB or CLOB values, the encrypted size (in bytes) has the following formula, where N is the original size of the plain text, and H is the size of the unencrypted hint string, if encryption is performed by **ENCRYPT\_TDES**:

$$N + H + 24 \text{ bytes.}$$

For BLOB or CLOB values that **ENCRYPT\_AES** encrypts, the overhead is larger:

$$N + H + 32 \text{ bytes.}$$

## Example of Column Level Encryption

The following example illustrates how to use the built-in encryption and decryption functions of Informix® to create and use a table that stores encrypted credit card numbers in a column that has a character data type.

| N        | ENCRYPT_TDES No Hint | ENCRYPT_AES No Hint | ENCRYPT_TDES With Hint | ENCRYPT_AES With Hint |
|----------|----------------------|---------------------|------------------------|-----------------------|
| 1 to 7   | 35                   | 43                  | 87                     | 99                    |
| 8 to 15  | 43                   | 43                  | 99                     | 99                    |
| 16 to 23 | 55                   | 67                  | 107                    | 119                   |
| 24 to 31 | 67                   | 67                  | 119                    | 119                   |
| 32 to 39 | 75                   | 87                  | 131                    | 139                   |
| 40 to 47 | 87                   | 87                  | 139                    | 139                   |
| 100      | 163                  | 171                 | 215                    | 227                   |
| 200      | 299                  | 299                 | 355                    | 355                   |
| 500      | 695                  | 707                 | 747                    | 759                   |

If the column size is smaller than the data size returned by encryption functions, the encrypted value is truncated when it is inserted. In this case, it will not be possible to decrypt the data, because the header will indicate that the length should be longer than the data value that the column contains.

These formulae and the values returned by the **LENGTH** function, however, indicate that the table schema in the next example can store the encrypted form of 16-digit credit card numbers (with a hint).

## Implementing column-level encryption

The following steps create a table from which a user who knows the password can retrieve rows that include one column of encrypted data.

1. Create a database table containing at least one column of type BLOB, CLOB, or a character data type of sufficient length to store the encrypted values. For example, the following statement creates a table called **customer** in which the column **creditcard** can store encrypted credit card numbers:

```
CREATE TABLE customer (id CHAR(20), creditcard CHAR(107));
```

2. Specify a password (and optional hint) and insert encrypted data:

```
SET ENCRYPTION PASSWORD 'credit card number is encrypted'
WITH HINT 'Why is this difficult to read?';
INSERT INTO customer VALUES ('Alice',
encrypt_tdes('1234567890123456'));
INSERT INTO customer VALUES ('Bob',
encrypt_tdes('2345678901234567'));
```

3. Query the encrypted data, using a decryption function:

```
SELECT id, DECRYPT_CHAR(creditcard,
'credit card number is encrypted') FROM customer;
```

The following query calls a decryption function in the WHERE clause, using the *session password* default, rather than an explicit *password* argument:

```
SELECT id FROM customer
WHERE DECRYPT_CHAR(creditcard) = '2345678901234567';
```

Column level encryption offers the coding convenience of passing the implicit *session password* for all rows with encrypted columns, and in multiple encryption and decryption function calls in the same SQL statement. Confidentiality of the data, however, requires users who know the password on encrypted columns to avoid compromising its secrecy. Triggers and UDRs, for example, should always use the *session password*, rather than explicit *password* arguments if they invoke the encryption or decryption functions.

The DBSA can manage highly confidential data with column level encryption. Informix® does not, however, prevent users with sufficient privileges from entering data encrypted by some other password into a table whose other rows use the designated column level encryption password.

## DECRYPT\_CHAR Function

The **DECRYPT\_CHAR** function accepts as its first argument an *encrypted\_data* character string that can have any character type (CHAR, LVARCHAR, NCHAR, NVARCHAR, or VARCHAR). You must specify a *password* as its second argument, unless the SET ENCRYPTION statement has specified for this session the same *session password* by which the first argument was encrypted.

The **DECRYPT\_CHAR** function also accepts as its first argument an *encrypted\_data* large object of type BLOB or CLOB. You must specify a password as its second argument, unless the SET ENCRYPTION statement has specified as the default for this session the same *password* by which the first argument was encrypted. If the call to **DECRYPT\_CHAR** is successful, it returns a CLOB large object that contains the plain text version of the *encrypted\_data* argument.

If the call to **DECRYPT\_CHAR** with an encrypted string argument is successful, it returns a character string that contains the plain text version of the *encrypted\_data* argument. The following example returns a character string containing a decrypted value from the **ssid** column of the **engineers** table for the row whose **empno** value is 287:

```
SELECT DECRYPT_CHAR (ssid) FROM engineers WHERE empno = 287;
```

If the first argument to **DECRYPT\_CHAR** is not an encrypted value, or if the second argument (or the default *password* specified by SET ENCRYPTION) is not the *password* that was used when the first argument was encrypted, Informix® issues an error, and the call to **DECRYPT\_CHAR** fails. (See the description of the [GETHINT Function on page 1290](#) for one possible action to take when you cannot remember the *password* that was used for encryption.)

Do not use **DECRYPT\_CHAR** (or any other decryption function) to create a functional index on an encrypted column. This would store the decrypted values as plain text data in the database, defeating the purpose of encryption.

For additional information about using data encryption in column values of Informix® databases, see [Encryption and decryption functions on page 1281](#), and [SET ENCRYPTION PASSWORD statement on page 896](#).

## DECRYPT\_BINARY Function

The **DECRYPT\_BINARY** function accepts as its first argument an *encrypted\_data* large object of type BLOB or CLOB. You must specify a *password* as its second argument, unless the SET ENCRYPTION statement has specified as the default for this session the same *password* by which the first argument was encrypted.

If the call to **DECRYPT\_BINARY** is successful, it returns a BLOB or CLOB large object that contains the plain text version of the *encrypted\_data* argument. The decrypted BLOB or CLOB object is temporarily stored in the default sbspace that the SBSPACENAME configuration parameter setting specifies.

If the first argument to **DECRYPT\_BINARY** is an encrypted value of a character data type, Informix® invokes the **DECRYPT\_CHAR** function and attempts to decrypt the specified value.

If the first argument to **DECRYPT\_BINARY** is not an encrypted value, or if the second argument (or the default *password* specified by SET ENCRYPTION) is not the *password* that was used when the first argument was encrypted, Informix® issues an error, and the call to **DECRYPT\_BINARY** fails. (See the description of the [GETHINT Function on page 1290](#) for one possible action to take when you cannot remember the *password* that was used for encryption.)

Do not use **DECRYPT\_BINARY** (or any other decryption function) to create a functional index on an encrypted column. This would store the decrypted values as plain text data in the database, defeating the purpose of encryption.

For additional information about using data encryption in column values of Informix® databases, see [Encryption and decryption functions on page 1281](#), and [SET ENCRYPTION PASSWORD statement on page 896](#).

## ENCRYPT\_AES Function

The **ENCRYPT\_AES** function returns an encrypted value that it derives by applying the AES (Advanced Encryption Standard) algorithm to its first argument, which must be an unencrypted character expression or a smart large object (that is, a BLOB or CLOB data type). A character argument can have a length of up to 32640 bytes if an explicit or default *hint* is used, or 32672 bytes if no *hint* (or a NULL *hint*) is specified. Theoretical size limits on BLOB or CLOB arguments are many orders of magnitude larger, but practical limits might be imposed by your hardware, or by time required for encryption and decryption. The encrypted BLOB or CLOB object is temporarily stored in the default sbspace that the SBSPACENAME configuration parameter specifies.

You must specify a *password* as its second argument, unless a SET ENCRYPTION statement has specified a *session password*, which the database server uses by default if you omit the second argument. If a *session password* has been set, any *password* that you specify overrides the *session password* for the returned value of this function call. The explicit or default *password* will also be required for any subsequent decryption of the returned encrypted value. A valid *password* must have at least 6 bytes but no more than 128.

You can optionally specify a *hint* as the third argument. If the SET ENCRYPTION statement specified a default *hint* for this session, and you specify no *hint*, that default *hint* is stored in an encrypted form within the returned value. Any *hint* that you specify overrides the default *hint*. A valid *hint* can be no longer than 32 bytes. You can use consecutive quotation marks ( " ) to specify a NULL *hint*. If you specify an explicit *hint*, you must also specify an explicit *password*.

The purpose of the *hint* is to help users to remember the *password*. For example, if the *password* is "buggy," you might define the hint as "whip." Neither string is restricted to a single word, but the size of the *hint* contributes to the size of the returned value. If you subsequently cannot remember the *hint*, use the returned value from **ENCRYPT\_AES** as the argument to **GETHINT** to retrieve the *hint*.

The following example calls **ENCRYPT\_AES** from the VALUES clause of an INSERT statement that stores in **tab1** a plain-text string and an *encrypted\_data* value that **ENCRYPT\_AES** returns from its 12-byte first argument. Here SET ENCRYPTION defines a *session password* and *hint* that are used as default second and third arguments to the **ENCRYPT\_AES** function:

```
EXEC SQL SET ENCRYPTION PASSWORD 'CHARYBDIS' WITH HINT 'messina';
EXEC SQL INSERT INTO tab1 VALUES ('abcd', ENCRYPT_AES(111-222-3333));
```

The call to **ENCRYPT\_AES** fails with an error if the *password* argument is omitted when no *session password* has been set, or if the length of an explicit *password* argument is shorter than 6 bytes or longer than 128 bytes.

In some contexts, an error is issued if the encrypted returned value is too large to be stored by the data type that receives it.

For additional information about using data encryption in column values of Informix® databases, see [Encryption and decryption functions on page 1281](#), and [SET ENCRYPTION PASSWORD statement on page 896](#).

## ENCRYPT\_TDES Function

The **ENCRYPT\_TDES** function returns a value that is the result of encrypting a character expression, or a BLOB or CLOB value, by applying the TDES (Triple Data Encryption Standard, which is sometimes also called DES3) algorithm to its first argument. This algorithm is slower than the AES algorithm that is used by the **ENCRYPT\_AES** function, but is considered somewhat more secure. The disk space required as encryption overhead resembles that of **ENCRYPT\_AES**, but is somewhat smaller because of the smaller block size of ENCRYPT\_TDES. (See "Calculating storage requirements for encrypted data" [Calculating storage requirements for encrypted data on page 1285](#) for a discussion of how to estimate the size of encrypted character strings.) For BLOB or CLOB values, the encrypted object is temporarily stored in the default sbspace that the SBSPACENAME configuration parameter specifies.

Those differences in performance, tamper-resistance, and in the returned *encrypted\_data* size that the previous paragraph lists are the practical differences between the **ENCRYPT\_TDES** and **ENCRYPT\_AES** functions, which otherwise follow the same rules, defaults, and restrictions that appear in the description of **ENCRYPT\_AES** on the previous page in regard to the following features:

- The required first argument (the plain text *data* value to be encrypted)
- The explicit or default second argument (the *password* string that must also be an argument to **DECRYPT\_CHAR** or **DECRYPT\_BINARY** to decrypt the returned *encrypted\_data* value). This must be specified unless a default *session password* has been set by the SET ENCRYPTION statement
- The optional third argument (the *hint* value) that might assist users who forget the *password*. If you subsequently cannot remember an explicit or default *hint* that was defined for *password*, you can use the returned value from **ENCRYPT\_TDES** as the argument to **GETHINT** to retrieve the *hint*.

The following example calls **ENCRYPT\_TDES** from the SET clause of an UPDATE statement. Here the *session password* is 'PERSEPHONE' and the *hint* string is "pomegranate", with column **colU** of table **tabU** the *data* argument. Because the WHERE clause condition of "1=1" is true for all rows of **tabU**, the effect of this statement is to replace every plain text **colU** value with encrypted strings returned by the algorithm that **ENCRYPT\_TDES** implements:

```
EXEC SQL SET ENCRYPTION PASSWORD 'PERSEPHONE' WITH HINT 'pomegranate';
EXEC SQL UPDATE tabU SET colU = ENCRYPT_TDES (colU) WHERE 1=1;
```

This example assumes that the character data type of **colU** is of sufficient size to store the new encrypted values without truncation. (A more cautious example might execute an appropriate ALTER TABLE statement before the UPDATE.)

For additional information about using data encryption in column values of Informix® databases, see [Encryption and decryption functions on page 1281](#), and [SET ENCRYPTION PASSWORD statement on page 896](#).

## GETHINT Function

The **GETHINT** function returns a character string that a previously executed SET ENCRYPTION PASSWORD statement defined for the *password* that was used when *encrypted\_data* was encrypted by the **ENCRYPT\_AES** function or by the **ENCRYPT\_TDES** function. This *hint* string typically provides information that helps the user to specify the *password* needed to return the plain text version of *encrypted\_data* with the **DECRYPT\_CHAR** or **DECRYPT\_BINARY** decryption function. The *hint* string, however, should not be the same as the *password*. In the following example, a query returns the *hint* string into a host variable called **myhint**:

```
EXEC SQL SELECT GETHINT(creditcard) INTO :myhint
FROM customer WHERE id = :myid;
```

An error is returned, rather than a *hint* string, if the *encrypted\_data* argument to the **GETHINT** function is not an encrypted string or an encrypted large object.

For additional information about using data encryption in column values of Informix® databases, see [Encryption and decryption functions on page 1281](#), and [SET ENCRYPTION PASSWORD statement on page 896](#).

## Exponential and Logarithmic Functions

Exponential and logarithmic functions take at least one argument and return a FLOAT data type.

The exponential and logarithmic functions have the following syntax.

Exponential and Logarithmic Functions

**EXP**(*float\_expression*)

**LN**(*float\_expression*)

**LOGN**( *float\_expression*)

**LOG10** (*float\_expression*)

| Element                 | Description  | Restrictions   | Syntax                                  |
|-------------------------|--|--|---|
| <i>float_expression</i> | An argument to the <b>EXP</b> , <b>LN</b> , <b>LOGN</b> , or <b>LOG10</b> functions. For the meaning of <i>float_expression</i> in these functions, see the individual heading for each function on the pages that follow. | The domain is the set of real numbers, and the range is the set of positive real numbers | <a href="#">Expression on page 1193</a> |

## EXP Function

The **EXP** function returns the exponent of a numeric expression.

The following example returns the exponent of 3 for each row of the **angles** table:

```
SELECT EXP(3) FROM angles;
```

For this function, the base is always e, the base of natural logarithms, as the following example shows:

```
e=exp(1)=2.718281828459
```

When you want to use the base of natural logarithms as the base value, use the **EXP** function. If you want to specify a particular value to raise to a specific power, see the [POW Function on page 1259](#).

## LN function

The **LN** function is an alias for the **LOGN** function, and returns the natural logarithm of a numeric argument. This value is the inverse of the exponential value.

LN Function

**LN**(*float\_expression*)

The following query returns the natural logarithm of **population** for each row in the **history** table:

```
SELECT LN(population) FROM history WHERE country='US'
ORDER BY date;
```

## LOG10 Function

The **LOG10** function returns the log of a value to base 10. The following example returns the log base 10 of distance for each row of the **travel** table:

```
SELECT LOG10(distance) + 1 digits FROM travel;
```

## LOGN Function

The **LOGN** function returns the natural logarithm of a numeric argument.

This return value is the inverse of the exponential value that the **EXP** function returns from the same argument.

The following query returns the natural log of **population** for each row of the **history** table:

```
SELECT LOGN(population) FROM history WHERE country='US'
ORDER BY date;
```

## NVL2 Function

Returns the second argument when the first argument is not NULL. If the first argument is NULL, the third argument is returned.

NVL2 Function

**NVL2**(*expression,result-expression,else-expression* )

The NVL2 function is a synonym for the following code:

```
CASE WHEN expression IS NOT NULL
      THEN result-expression
      ELSE else-expression
```

## HEX Function

The **HEX** function returns the hexadecimal encoding of an integer expression.

HEX Function

**HEX**(*int\_expression* )

| Element               | Description  | Restrictions   | Syntax                                  |
|-----------------------|--|--|---|
| <i>int_expression</i> | Expression for which you want the hexadecimal equivalent | Must be a literal integer or some other expression that returns an integer | <a href="#">Expression on page 1193</a> |

The next example displays the data type and column length of the columns of the **orders** table in hexadecimal format. For MONEY and DECIMAL columns, you can then determine the precision and scale from the lowest and next-to-the-lowest bytes. For VARCHAR and NVARCHAR columns, you can determine the minimum space and maximum space from the lowest and next-to-the-lowest bytes. For more information about encoded information, see the *Informix® Guide to SQL: Reference*.

```
SELECT colname, coltype, HEX(collength)
FROM syscolumns C, systables T
WHERE C.tabid = T.tabid AND T.tabname = 'orders';
```

The following example lists the names of all the tables in the current database and their corresponding tblspace number in hexadecimal format.

```
SELECT tabname, HEX(partnum) FROM systables;
```

The two most significant bytes in the hexadecimal number constitute the dbspace number. They identify the table in **oncheck** output in Informix®.

The **HEX** function can operate on an expression, as the next example shows:

```
SELECT HEX(order_num + 1) FROM orders;
```

## Length functions

Use length functions to determine the length of a character column, string, or variable, or of the value returned by a character expression, or (for **CHAR\_LENGTH** in multibyte locales) the number of logical characters.

Length Functions

594

### LENGTH LEN

### CHAR\_LENGTH CHARACTER\_LENGTH

### OCTET\_LENGTH

(  
 Quoted String<sup>597</sup>  
<sup>595596</sup> *variable\_name*

*table*.

*column*

)

| Element         | Description  | Restrictions                    | Syntax                                  |
|-----------------|--|---------------------------------|---|
| <i>column</i>   | Name of a column in <i>table</i>                               | Must have a character data type | <a href="#">Identifier on page 1456</a> |
| <i>table</i>    | Name of the table in which the specified column occurs         | Must exist                      | <a href="#">Identifier on page 1456</a> |
| <i>variable</i> | Host variable or SPL variable that contains a character string | Must have a character data type | See language-specific rules for names.  |

Each of these functions has a distinct purpose:

- **LENGTH** (also known as **LEN**)
- **OCTET\_LENGTH**
- **CHAR\_LENGTH** (also known as **CHARACTER\_LENGTH**)

594. Informix® extension

595. ESQL/C

596. SPL Language

597. See [Quoted String on page 1424](#)

## LENGTH Function

The **LENGTH** function (also called **LEN**) returns the number of bytes in a character column, but excluding any trailing blank spaces.

For BYTE or TEXT columns, **LENGTH** returns the full number of bytes, including any trailing blank spaces.

In Informix® ESQL/C, **LENGTH** can also return the length of a character variable.

The following example illustrates the use of the **LENGTH** function:

```
SELECT customer_num, LENGTH(fname) + LENGTH(lname),  
       LENGTH('How many bytes is this?')  
FROM customer WHERE LENGTH(company) > 10;
```

The next example calls the function by its other name, **LEN**;

```
EXECUTE FUNCTION LEN("www.ibm.com");
```

The SQL statement above returns the integer value **11**.

See also the discussion of **LENGTH** in the *Informix® GLS User's Guide*.

## OCTET\_LENGTH Function

The **OCTET\_LENGTH** returns the number of bytes in a character column, including any trailing blank spaces. See also the *Informix® GLS User's Guide*.

## CHAR\_LENGTH Function

The **CHAR\_LENGTH** function returns the number of logical characters in its argument, which can be a character column, a character variable, or a quoted string. This built-in function can also be invoked as **CHARACTER\_LENGTH**.

In the default U.S. English locale and other single-byte locales, **CHAR\_LENGTH** behaves exactly like the **LENGTH** function, and returns the number of bytes in its argument.

For multibyte code sets, however, which various Unicode, East Asian, and other nondefault locales support, the return value can be less than the number of bytes in the argument. For a discussion of this function, see the *Informix® GLS User's Guide*.

## Security Label Support Functions

The security label support functions enable users to manipulate security labels. A security label can be referenced in three different ways:

- A name, as declared in the CREATE SECURITY LABEL or RENAME SECURITY LABEL statement.
- A list of values for each component of the security policy of the security label.
- An internal encoded value that the IDSSECURITYLABEL data type stores.

These functions can convert between the various forms of a security label. They are typically used to specify a label in DML operations on data rows that are secured by label-based access control (LBAC). In these operations, however, the security label support functions do not provide any more access to protected data than is already provided by the security credentials of the user who invokes the function.

Security Label Support Function

**SECLABEL\_TO\_CHAR**( '*policy*',*column* )

**SECLABEL\_BY\_COMP**( '*policy*',

:

*component*

(

, *element*

)

)

**SECLABEL\_BY\_NAME** (*policy*, '*label*')

| Element          | Description  | Restrictions   | Syntax                                     |
|------------------|--|--|--|
| <i>column</i>    | A column of type IDSSECURITYLABEL  | Must exist and must store a label of the <i>policy</i>                     | <a href="#">Identifier on page 1456</a>    |
| <i>component</i> | Value of a component of the <i>policy</i>  | Must exist and must be a component of the <i>policy</i>                    | <a href="#">Quoted String on page 1424</a> |
| <i>element</i>   | Value of an element within a list of values of the <i>component</i>                  | Must exist and must be elements of a single component of the <i>policy</i> | <a href="#">Quoted String on page 1424</a> |
| <i>label</i>     | Identifier of the security label whose value the function returns                    | Must exist and must be a label of the <i>policy</i>                        | <a href="#">Quoted String on page 1424</a> |
| <i>policy</i>    | The security policy supported by the security label whose value the function returns | Must exist and must be the security policy that secures the table          | <a href="#">Quoted String on page 1424</a> |

These functions return a security label of the specified security *policy*. They can be used within DML statements that reference a protected database table, but they can also evaluate to a security label in other calling contexts. Each of these functions requires a different argument list:

- **SECLABEL\_TO\_CHAR** requires the security policy name and an expression that returns an `IDSSECURITYLABEL` object, such as the name of a column of that data type.
- **SECLABEL\_BY\_COMP** requires the security policy name and the values of the individual components of the security label.
- **SECLABEL\_BY\_NAME** requires the names of the security policy and of the security label.

## SECLABEL\_BY\_NAME Function

The **SECLABEL\_BY\_NAME** function enables users to provide a security label directly by specifying its name.

The following `INSERT` statement inserts a row into table **T1**, which is protected by the security policy called '**MegaCorp**'. The `VALUES` clause of the `INSERT` statement provides the security label '**mylabel**' for the row to be inserted by using the **SECLABEL\_BY\_NAME** function.

```
INSERT INTO T1 VALUES (SECLABEL_BY_NAME ('MegaCorp', 'mylabel'), 1, 'xyz');
```

The success of this **SECLABEL\_BY\_NAME** function call does not guarantee success of the `INSERT` operation in this example, because whether or not the user has sufficient security credentials to insert the label **mylabel** into the row is subject to the **IDSLBACWRITE** rules of the **MegaCorp** security policy.

## SECLABEL\_BY\_COMP Function

The **SECLABEL\_BY\_COMP** function returns an `IDSSECURITYLABEL` object, which is a security label in its internal encoded string format. This function enables users to provide a security label directly by specifying its component values.

If a security label component requires multiple values, then such multiple values can be specified by putting those values between parenthesis as in `(value_1, value_2, ...)`. When a component in a particular security label needs to be empty, it can be specified by putting nothing between an opening and a closing parenthesis, as in `()`. Because the blank space (ASCII 32) is a valid character in an element value for a security component, any blank space appearing in the security label string is treated as part of the element value for that component.

The security label string is limited to a maximum of 32 kilobytes. An error is returned if the string length exceeds this limit.

The following `INSERT` statement inserts a row into table **T1** which is protected by the security policy called '**MegaCorp**' that has three components: '**level**', '**compartments**', and '**groups**'. Here the user provides a security label for the row to be inserted by specifying the **SECLABEL\_BY\_COMP** function. The security label in this example has the value '**VP**' for the **level** component, the value '**Marketing**' for the **compartments** component, and the value '**West**' for the **groups** component. In the arguments to **SECLABEL\_BY\_COMP**, colon symbols separate these security component element values, and quotation marks delimit the list of component values of the security label.

```
INSERT INTO T1
VALUES (SECLABEL_BY_COMP ('MegaCorp', 'VP:Marketing:West'), 1, 'xyz');
```

In the next example, the INSERT statement inserts a row in table **T1** which is protected by the same **MegaCorp** security policy, which has the same three components as in the previous example: **level**, **compartments**, and **groups**. The user provides the security label for the row to be inserted by specifying the policy name and a list of security component elements as arguments to the **SECLABEL\_BY\_COMP** function. Here the security label has the value **'Director'** for the **level** component, the values **'HR'** and **'Finance'** for the **compartments** component, and the value **'East'** for the **groups** component.

```
INSERT INTO T1
VALUES (SECLABEL_BY_COMP ('MegaCorp', 'Director:(HR,Finance):East'), 1, 'xyz');
```

The following example inserts a row into table **T1** which is protected by the **MegaCorp** security policy, whose three components are **level**, **compartments**, and **groups**. The **SECLABEL\_BY\_COMP** function specifies the security label for the row to be inserted. The security label in this example has the value **'CEO'** for level **component**, the empty set for the **compartments** component, and the value **'EntireRegion'** for the **groups** component.

```
INSERT INTO T1
VALUES (SECLABEL_BY_COMP ('MegaCorp', 'CEO():EntireRegion'), 3, 'abc');
```

As in all of these examples, the success of the **SECLABEL\_BY\_COMP** function call does not guarantee the success of the INSERT statement, because the security credentials of the user are first compared to the security label that protects table **T1**, using the **IDSLBACRWRITE** rules of the **MegaCorp** security policy, before the database server allows or denies write access for inserting the new row.

## SECLABEL\_TO\_CHAR Function

The **SECLABEL\_TO\_CHAR** function returns a security label in the security label string format.

The security credentials of the user executing this function can affect the output of the function. An element of a security label component is not included in the output if the user does not have read access to that element. A user has read access to an element if the security credentials of the user provide read access to data that is protected by a security label containing only that element and no other elements.

For the rule set **IDSLBACRULES**, only components of type **TREE** can contain elements to which a user does not have read access to a subset of elements. For other types of component, if any element blocks read access, then the user cannot read the row at all. Thus, only security components of type **TREE** can have a subset of security component elements excluded in this way.

For example, if the **TREE** type component of the security label of a user is **{A}** and the **TREE** type component of a row security label is **{A, B}**, then only component **A** is returned, and the user is not aware that **B** existed in the row security label. If the user holds an exemption on the **IDSLBACREADTREE** rule, however, the returned security components are both **A** and **B**.

In the next example, the **MegaCorp** security policy has a security label called **mylabel** that consists of a **level** component whose value is **'Director'**, and a **compartments** component with the values **'HR'** and **'Finance'**. A user to whom **'mylabel'** was granted has inserted a row with that security label into table **T1**. In this context, the security label string returned by the **SECLABEL\_TO\_CHAR** function in the following SELECT statement on **T1** is as follows.

```
SELECT SECLABEL_TO_CHAR ('MegaCorp', C1) FROM T1;
```

Row returned:

```
'Director:(HR,Finance)'
```

The success of this query implies that the **SECLABEL\_TO\_CHAR** function succeeded, and that the security credentials of the user were sufficient, according to the **IDSLBACREAD** rules of the **MegaCorp** security policy, for the database server to allow read access to the values of the security policy name and of the security label components."

The security label string is limited to a maximum size of 32 kilobytes. If the length of the security label string to be returned exceeds this upper limit, a warning is issued, and a truncated 32 kilobyte string is returned.

## SIGN function

The SIGN function returns an indicator of the sign of the argument.

SIGN Function

**SIGN**(*expression*)

If the argument is less than zero, **-1** is returned. If the argument equals zero, **0** is returned. If the argument is greater than zero, **1** is returned. The result returned is always an integer with one of these values.

## Smart-Large-Object Functions

The smart-large-object functions support objects of BLOB and CLOB data types:

The smart-large-object functions have the following syntax:

Smart-Large-Object Functions

**FILETOBLOB FILETOCLOB**

(*pathname*,*file\_destination*

,*table* ,*column*

)

**LOTOFILE**(

*BLOB\_column* *CLOB\_column*

,*pathname*,*file\_destination*)

**LOCOPY**(

*BLOB\_column* *CLOB\_column*

,*table* ,*column*

)

| Element                     | Description   | Restrictions  | Syntax                                     |
|-----------------------------|---|---|--|
| BLOB_column,<br>CLOB_column | A column of type BLOB; a column of type CLOB                          | The <i>column</i> data type must be BLOB or CLOB  | <a href="#">Identifier on page 1456</a>    |
| <i>column</i>               | Column within <i>table</i> for the copy of the BLOB or CLOB value     | Must have CLOB or BLOB as its data type   | <a href="#">Quoted String on page 1424</a> |
| <i>file_destination</i>     | The system on which to put or get the smart large object              | The only valid values are the strings 'server' or 'client'  | <a href="#">Quoted String on page 1424</a> |
| <i>pathname</i>             | Directory path and filename to locate the smart large object          | No more than 256 bytes. Must exist on <i>file_destination</i> system. See also <a href="#">Pathnames with Commas on page 1301</a> . | <a href="#">Quoted String on page 1424</a> |
| <i>table</i>                | Table containing <i>column</i> for the copy of the BLOB or CLOB value | A comma (not a period) separates the 'table' and 'column' arguments   | <a href="#">Quoted String on page 1424</a> |

## FILETOBLOB and FILETOCLOB Functions

The **FILETOBLOB** function creates a BLOB value for data that is stored in a specified operating-system file. Similarly, the **FILETOCLOB** function creates a CLOB value for a data value that is stored in an operating-system file.

These functions determine the operating-system file to use from the following parameters:

- The *pathname* parameter identifies the directory path and name of the source file.
- The *file destination* parameter identifies the computer, 'client' or 'server', on which this file resides:
  - Set *file destination* to 'client' to identify the client computer as the location of the source file. The *pathname* can be either a full pathname or relative to the current directory.
  - Set *file destination* to 'server' to identify the server computer as the location of the source file. The *pathname* must be a full pathname.

The *table* and *column* parameters are optional:

- If you omit *table* and *column*, the **FILETOBLOB** function creates a BLOB value with the system-specified storage defaults, and the **FILETOCLOB** function creates a CLOB value with the system-specified storage defaults.

These functions obtain the system-specific storage characteristics from either the ONCONFIG file or the sbspace. For more information on system-specified storage defaults, see the *Informix® Administrator's Guide*.

- If you specify *table* and *column*, the **FILETOBLOB** and **FILETOCLOB** functions use the storage characteristics from the specified column for the BLOB or CLOB value that they create.

The **FILETOBLOB** function returns a handle value (a pointer) to the new BLOB value. Similarly, **FILETOCLOB** returns a handle value to the new CLOB value. Neither function actually copies the smart-large-object value into a database column. You must assign the BLOB or CLOB value to the appropriate column.

The **FILETOCLOB** function performs any code-set conversion that might be required when it copies the file from the client or server computer to the database.

The following INSERT statement uses the **FILETOCLOB** function to create a CLOB value from the value in the **smith.rsm** file:

```
INSERT INTO candidate (cand_num, cand_lname, resume)
VALUES (2, 'Smith', FILETOCLOB('smith.rsm', 'client'));
```

In the preceding example, the **FILETOCLOB** function reads the **smith.rsm** file in the current directory on the client computer and returns a handle value to a CLOB value that contains the data in this file. Because the **FILETOCLOB** function does not specify a table and column name, this new CLOB value has the system-specified storage characteristics. The INSERT statement then assigns this CLOB value to the **resume** column in the **candidate** table.

The following INSERT statement uses the **FILETOBLOB** function to create a BLOB value from the value in the **photos.xxx** file on the local database server, and insert that value into the **election2008** table of the **rdb** database, which is another database of the local database server:

```
INSERT INTO rdb@:election2008 (cand_pic)
VALUES (FILETOBLOB('C:\tmp\photos.xxx', 'server',
'candidate', 'cand_photo'));
```

In the preceding example, the **FILETOBLOB** function reads the **photos.xxx** file in the specified directory on the local database server and returns a handle value to a BLOB value that contains the data in this file. The INSERT statement then assigns this BLOB value to the **cand\_pic** column in the **election2008** table in the **rdb** database of the local database server. This new BLOB value has the storage characteristics of the **cand\_photo** column in the **candidate** table in the local database.

In the following example, the new BLOB value has the storage characteristics of the **cand\_pix** column in the **election96** table in the **rdb2** database, where **rdb1** and **rdb2** are databases of the local Informix® instance:

```
INSERT INTO rdb1:election2008 (cand_pic)
VALUES (FILETOBLOB('C:\tmp\photos.xxx', 'server',
'rdb2:election96', 'cand_pix'));
```

When you qualify the **FILETOBLOB** or **FILETOCLOB** function with the name of a remote database and a remote database server, the *pathname* and the *file destination* become relative to the remote database server.

When you specify `server` as the file destination, as the following example shows, the **FILETOBLOB** function looks for the source file (in this case, **photos.xxx**) on the remote database server:

```
INSERT INTO rdb@rserv:election (cand_pic)
VALUES (rdb@rserv:FILETOBLOB('C:\tmp\photos.xxx', 'server'));
```

When you specify `client` as the file destination, however, as in the following example, the **FILETOBLOB** function looks for the source file (in this case, **photos.xxx**) on the local client computer:

```
INSERT INTO rdb@rserv:election (cand_pic)
VALUES (rdb@rserv:FILETOBLOB('photos.xxx', 'client'));
```

## Pathnames with Commas

If a comma ( , ) symbol is within the *pathname* of the function, the database server expects the pathname to have the following format:

```
"offset, length, pathname"
```

For pathnames that contain a comma, you must also specify an offset and length, as in the following example:

```
FILETOBLOB("0,-1,/tmp/blob,x","server");
```

The first term in the quoted *pathname* string is an *offset* of 0, which instructs the database server to begin reading at the start of the file.

The second term is a *length* of -1, which instructs the database server to continue reading until the end of the entire file.

The third term is the */tmp/blob,x* *pathname*, specifying which file to read. (Notice the comma symbol that precedes the x.)

Because the *pathname* includes a comma, the comma-separated *offset* and *length* specifications are necessary in this example to avoid an error when **FILETOBLOB** is called. You do not need to specify *offset* and *length* for pathnames that include no comma, but including 0,-1, as the initial characters of the pathname string avoids this error for any valid pathname.

## LOTOFILE Function

The **LOTOFILE** function copies a smart large object to an operating-system file.

The first parameter specifies the BLOB or CLOB column to copy. The function determines what file to create from the following parameters:

- The *pathname* identifies the directory path and the source file name.
- The *file destination* identifies the computer, 'client' or 'server', on which this file resides:
  - Set *file destination* to 'client' to identify the client computer as the location of the source file. The *pathname* can be either a full pathname or a path relative to the current directory.
  - Set *file destination* to 'server' to identify the server computer as the location of the source file. The full pathname is required.

By default, the **LOTOFILE** function generates a filename of the form:

```
file.hex_id
```

In this format, *file* is the filename you specify in *pathname* and *hex\_id* is the unique hexadecimal smart-large-object identifier. The maximum number of digits for a smart-large-object identifier is 17. Most smart large objects, however, would have an identifier with fewer digits.

For example, suppose that you specify a UNIX™ *pathname* value as follows:

```
'/tmp/resume'
```

If the CLOB column has the identifier **203b2**, then **LOTOFILE** creates the file:

```
/tmp/resume.203b2
```

For another example, suppose that you specify a Windows™ *pathname* value as follows:

```
'C:\tmp\resume'
```

If the CLOB column has an identifier of **203b2**, the **LOTOFILE** function would create the file:

```
C:\tmp\resume.203b2
```

To change the default filename, you can specify the following wildcards in the filename of the *pathname*:

- One or more contiguous question mark ( ? ) characters in the filename can generate a unique filename.

The **LOTOFILE** function replaces each question mark with a hexadecimal digit from the identifier of the BLOB or CLOB column.

For example, suppose that you specify a UNIX™ *pathname* value as follows:

```
 '/tmp/resume?? .txt'
```

The **LOTOFILE** function puts 2 digits of the hexadecimal identifier into the name. If the CLOB column has an identifier of **203b2**, the **LOTOFILE** function would create the file:

```
/tmp/resume20.txt
```

If you specify more than 17 question marks, **LOTOFILE** ignores them.

- An exclamation ( ! ) point at the end of the filename indicates that the filename does not need to be unique.

For example, suppose that you specify a Windows™ *pathname* value as follows:

```
'C:\tmp\resume.txt!'
```

The **LOTOFILE** function does not use the smart-large-object identifier in the filename, so it generates the following file:

```
C:\tmp\resume.txt
```

If the filename that you specify already exists, **LOTOFILE** returns an error.

The **LOTOFILE** function performs any code-set conversion that might be required when it copies a CLOB value from the database to a file on the client or server computer.

When you qualify **LOTOFILE** with the name of a remote database and a remote database server, the BLOB or CLOB column, the *pathname*, and the *file destination* become relative to the remote database server.

When you specify `server` as the file destination, as in the next example, the **LOTOFILE** function copies the smart large object from the remote database server to a source file in the specified directory on the remote database server:

```
rdb@rserv:LOTOFILE(blob_col, 'C:\tmp\photo.gif!', 'server')
```

If you specify `client` as the file destination, as in the following example, the **LOTOFILE** function copies the smart large object from the remote database server to a source file in the specified directory on the local client computer:

```
rdb@rserv:LOTOFILE(clob_col, 'C:\tmp\essay.txt!', 'client')
```

## LOCOPY Function

The **LOCOPY** function creates a copy of a smart large object.

The first parameter specifies the BLOB or CLOB column to copy. The *table* and *column* parameters are optional.

- If you omit *table* and *column* arguments, the **LOCOPY** function creates a smart large object with system-specified storage defaults, and copies the data in the BLOB or CLOB column into it.

The **LOCOPY** function obtains the system-specific storage defaults from either the ONCONFIG file or the sbspace. For more information on system-specified storage defaults, see the *Informix® Administrator's Guide*.

- When you specify *table* and *column*, the **LOCOPY** function uses the storage characteristics from the specified *column* for the BLOB or CLOB value that it creates.

The **LOCOPY** function returns a handle value (a pointer) to the new BLOB or CLOB value. This function does *not* actually store the new smart-large-object value into a column in the database. You must assign the BLOB or CLOB value to the appropriate column.

The following Informix® ESQL/C code fragment copies the CLOB value in the **resume** column of the **candidate** table to the **resume** column of the **interview** table:

```
/* Insert a new row in the interviews table and get the
 * resulting SERIAL value (from sqlca.sqlerrd[1])
 */
EXEC SQL insert into interviews (intrv_num, intrv_time)
  values (0, '09:30');
intrv_num = sqlca.sqlerrd[1];

/* Update this interviews row with the candidate number
 * and resume from the candidate table. Use LOCOPY to
 * create a copy of the CLOB value in the resume column
 * of the candidate table.
 */
EXEC SQL update interviews
  SET (cand_num, resume) =
    (SELECT cand_num,
      LOCOPY(resume, 'candidate', 'resume')
     FROM candidate
     WHERE cand_lname = 'Haven')
  WHERE intrv_num = :intrv_num;
```

In the preceding example, the **LOCOPY** function returns a handle value for the copy of the CLOB **resume** column in the **candidate** table. Because the **LOCOPY** function specifies a table and column name, this new CLOB value has the storage characteristics of this **resume** column. If you omit the table (**candidate**) and column (**resume**) names, the **LOCOPY** function uses the system-defined storage defaults for the new CLOB value. The UPDATE statement then assigns this new CLOB value to the **resume** column in the **interviews** table.

In the following example, the **LOCOPY** function executes on the local database and returns a handle value on the local server for the copy of the BLOB **cand\_pic** column in the **election2008** table in **rdb**, which is another database of the local database server. The INSERT statement then assigns this new BLOB value to the **cand\_photo** column in the local **candidate** table.

```
INSERT INTO candidate (cand_photo)
  SELECT LOCOPY(cand_pic) FROM rdb:election2008;
```

When the **LOCOPY** function executes on the same database server as the original BLOB or CLOB column in a distributed query, it produces two copies of the BLOB or CLOB value, one in the remote database and the other in the local database, as the following two examples show.

In the first example, the **LOCOPY** function executes on the remote **rdb** database and returns a handle value in the remote database for the copy of the BLOB **cand\_pic** column in the remote **election2008** table. The INSERT statement then assigns this new BLOB value to the **cand\_photo** column in the local **candidate** table:

```
INSERT INTO candidate (cand_photo)
  SELECT rdb:LOCOPY(cand_pic)
  FROM rdb:election2008;
```

In the second example, the **LOCOPY** function executes on the local database and returns a handle value on the local database for the copy of the BLOB **cand\_photo** column in the local **candidate** table. The INSERT statement then assigns this new BLOB value to the **cand\_pic** column in the **election2008** table in the remote **rdb** database:

```
INSERT INTO rdb:election2008 (cand_pic)
  SELECT LOCOPY(cand_photo) FROM candidate;
```

The BLOB and CLOB arguments of the built-in **LOCOPY** function are built-in opaque data types. These can be values returned by cross-database DML operations or by cross-database function calls, but built-in opaque types do not support distributed operations across database server instances. If the local database and the **rdb** database are databases of different Informix® instances, the INSERT statements in the previous two examples fail with error -999.

## Time Functions

The time functions of Informix® accept DATE or DATETIME arguments, or character representation of a DATE or DATETIME value. They typically return DATE or DATETIME values, or convert information that they extract from DATE or DATETIME values into character strings or integers.

See also the descriptions of the **ROUND** and **TRUNC** functions, which can change the precision of DATE or DATETIME values, in the section [Algebraic Functions on page 1254](#).

## Time Functions

**DATE**(*non\_date\_expr*)**DAY LAST\_DAY MONTH QUARTER WEEKDAY YEAR***(date/dtime\_expr)***EXTEND**(*date/dtime\_expr**,first***TO** *last*

)

**MDY**(*month ,day,year*)**ADD\_MONTHS**(*date/dtime\_expr ,integer*)**MONTHS\_BETWEEN**(*date/dtime\_expr ,date/dtime\_expr*)**NEXT\_DAY**(*date/dtime\_expr ,weekday*)**TO\_CHAR**(*date/dtime\_expr num\_expr***TO\_DATE**(*char\_expression**,format\_string*

)

| Element                           | Description   | Restrictions   | Syntax  |
|-----------------------------------|---|--|---|
| <i>char</i><br><i>_expression</i> | Expression to be converted to a DATE or DATETIME value  | Must be a literal, host variable, expression, or column of a character data type                                     | <a href="#">Expression on page 1193</a>               |
| <i>date/dtime</i><br><i>_expr</i> | Expression that returns a DATE or DATETIME value  | Can be host variable, expression, column, or constant.   | <a href="#">Expression on page 1193</a>               |
| <i>day</i>                        | Expression that returns the number of a day of the month  | Must return integer > 0 but no greater than the number of days in the specified month                                | <a href="#">Expression on page 1193</a>               |
| <i>first</i>                      | Largest time unit in the result. If you omit <i>first</i> and <i>last</i> , the default <i>first</i> is YEAR. | Must be a DATETIME qualifier keyword that specifies a time unit no smaller than <i>last</i>                          | <a href="#">DATETIME Field Qualifier on page 1191</a> |
| <i>format_string</i>              | String that contains a format mask for the first argument   | Must be a character data type that specifies a valid format. Can be a column, host variable, expression, or constant | <a href="#">Quoted String on page 1424</a>            |
| <i>integer</i>                    | Expression that specifies a whole number of months  | Must evaluate to positive or negative integer  | <a href="#">Expression on page 1193</a>               |
| <i>last</i>                       | Smallest time unit in the result  | Must be a DATETIME qualifier keyword that specifies a time unit no smaller than <i>first</i>                         | <a href="#">DATETIME Field Qualifier on page 1191</a> |
| <i>month</i>                      | Expression that represents the number of the month  | Must evaluate to an integer in the range from 1 to 12, inclusive   | <a href="#">Expression on page 1193</a>               |

| Element              | Description  | Restrictions  | Syntax                                     |
|----------------------|--|---|--|
| <i>non_date_expr</i> | Expression that represents a value to be converted to a DATE data type | Typically an expression that returns a CHAR, DATETIME, or INTEGER value that can be converted to a DATE data type | <a href="#">Expression on page 1193</a>    |
| <i>num_expr</i>      | Expression that evaluates to a real number                             | Must return a numeric data type   | <a href="#">Expression on page 1193</a>    |
| <i>weekday</i>       | Abbreviated name of a day of the week                                  | A character data type containing a valid abbreviation for a day of the week                                       | <a href="#">Quoted String on page 1424</a> |
| <i>year</i>          | Number expression that represents a year                               | Must evaluate to a 4-digit integer. You cannot use a 2-digit abbreviation.  | <a href="#">Expression on page 1193</a>    |

## ADD\_MONTHS Function

The **ADD\_MONTHS** function takes a DATETIME or DATE expression as its first argument, and requires a second integer argument, specifying the number of months to add to the first argument value. The second argument can be positive or negative.

The value returned is the sum of the DATE or DATETIME value of the first argument, as an INTERVAL UNITS MONTH value, based on the number of months that the second argument specifies.

The returned data type depends on the data type of the first argument:

- If the first argument evaluates to a DATE value, **ADD\_MONTHS** returns a DATE value.
- If the first argument evaluates to a DATETIME value, **ADD\_MONTHS** returns a DATETIME YEAR TO FRACTION(5) value, with the same values for time units smaller than *day* as in the first argument.

If the *day* and *month* time units in the first argument specify the last day of the month, or if the resulting month has fewer days than the *day* in the first argument, then the returned value is the last day of the resulting month. Otherwise, the returned value has the same day of the month as the first argument.

The returned value can be in a different year, if the resulting month is later than December (or for negative second arguments, earlier than January) of the year in the first argument.

The following query calls the **ADD\_MONTHS** function twice in the Projection clause, using column expressions as arguments. Here the column names indicate the column data types, and the **DBDATE** setting is `MDY4/`:

```
SELECT a_serial, b_date, ADD_MONTHS(b_date, a_serial),
       c_datetime, ADD_MONTHS(c_datetime, a_serial)
FROM mytab WHERE a_serial = 7;
```

In this example **ADD\_MONTHS** returns DATE and DATETIME values:

```

a_serial      7
b_date        07/06/2007
(expression)  02/06/2008
c_datetime    2007-10-06 16:47:49.00000
(expression)  2008-05-06 16:47:49.00000

```

If you use a host variable to store the argument to **ADD\_MONTHS**, but the data type of the argument is not known at prepare time, Informix® assumes that the data type is DATETIME YEAR TO FRACTION(5). If at runtime, after the statement has been prepared, the user supplies a DATE value for the host variable, the database server issues error -9750. To prevent this error, specify the data type of the host variable by using a cast, as in this program fragment:

```

sprintf(query, ,
    select add_months(?::date, 6) from mytab);
EXEC SQL prepare selectq from :query;
EXEC SQL declare select_cursor cursor for selectq;
EXEC SQL open select_cursor using :hostvar_date_input;

EXEC SQL fetch select_cursor into :var_date_output;

```

## DATE Function

The **DATE** function converts its argument to a DATE value.

Its non-DATE argument can be any expression that can be converted to a DATE value, usually a CHAR, DATETIME, or INTEGER value. The following WHERE clause specifies a quoted string as its CHAR argument:

```
WHERE order_date < DATE('12/31/07')
```

When the **DATE** function interprets a CHAR non-DATE expression, it expects this expression to conform to any DATE format that the **DBDATE** environment variable specifies. For example, suppose **DBDATE** is set to `Y2MD/` when you execute the following query:

```
SELECT DISTINCT DATE('02/01/2008') FROM ship_info;
```

This SELECT statement generates an error, because the **DATE** function cannot convert this string expression. The **DATE** function interprets the first part of the date string (02) as the year and the second part (01) as the month.

For the third part (2008), the **DATE** function encounters four digits when it expects a two-digit day (valid day values must be between 01 and 31). It therefore cannot convert the value. For the SELECT statement to execute successfully with the `Y2MD/` value for **DBDATE**, the argument would need to be '08/02/01'. For information on the format of **DBDATE**, see the *Informix® Guide to SQL: Reference*.

For information on the order of precedence among Informix® environment variables that can specify the display and data entry format of DATE values, see the topic [Precedence of DATE and DATETIME format specifications on page 1416](#).

When you specify a positive INTEGER value for the non-DATE expression, the **DATE** function interprets this as the number of days after December 31, 1899.

If the integer value is negative, the **DATE** function interprets the value as the number of days before December 31, 1899. The following WHERE clause specifies an INTEGER value for the non-DATE expression:

```
WHERE order_date < DATE(365)
```

The database server searches for rows with an **order\_date** value less than December 31, 1900 (which is 12/31/1899 plus 365 days).

## DAY Function

The **DAY** function takes a DATE or DATETIME argument and returns the day of the month as an integer in the range from 1 to the number of days in the current month.

The following statement fragment calls the **DAY** function with the **CURRENT** function as its argument to compare **order\_date** column values to the current day of the month:

```
WHERE DAY(order_date) > DAY(CURRENT)
```

## MONTH Function

The **MONTH** function returns an integer corresponding to the *month* portion of its DATE or DATETIME argument.

Like the **DAY**, **YEAR**, **WEEKDAY**, and **QUARTER** built-in time functions, the **MONTH** function extracts information from a single DATE or DATETIME expression that is its argument. The return value is the ordinal position of that *month* within the sequence of months in a calendar year. On September 23, for example, the function expression `MONTH(TODAY)` returns 9,

The following example returns a number that can range from 1 through 12 to indicate the month when the order was placed:

```
SELECT order_num, MONTH(order_date) FROM orders;
```

## QUARTER Function

The **QUARTER** function returns an integer in the range 1 through 4 that corresponds to the *quarter* of the calendar year that includes its DATE or DATETIME argument.

For example, any date in January, February, or March returns the integer 1.

The argument must be an expression that evaluates to a DATE or DATETIME data type.

### Examples of QUARTER function expressions

The following function expression returns 3, because August is in the third quarter of the year.

```
QUARTER('2014-08-25')
```

The following example returns a number that can range from 1 through 4 to indicate the quarter when the order was placed:

```
SELECT order_num, QUARTER(order_date) FROM orders;
```

The following query includes `QUARTER` function expressions whose arguments are the `order_date` column and the `CURRENT` operator. The `WHERE` clause restricts the result set to qualifying rows with `order_date` values in quarters earlier in the current year than the current quarter:

```
SELECT * FROM orders
WHERE (QUARTER(order_date) < QUARTER(CURRENT))
      AND YEAR(order_date) = YEAR(CURRENT);
```

During the first quarter, however, this query returns no rows, because there can be no data from a quarter with a value less than the current quarter. That is, there is no quarter of value zero.

## WEEKDAY Function

The `WEEKDAY` function accepts a `DATE` or `DATETIME` argument, and returns an integer in the range from 0 to 6 that represents the day of the week.

As the return value, zero (0) represents Sunday, one (1) represents Monday, and so on.

The following query returns all the orders that were paid on the same day of the week as the current date:

```
SELECT * FROM orders
WHERE WEEKDAY(paid_date) = WEEKDAY(CURRENT);
```

## YEAR Function

The `YEAR` function takes a `DATE` or `DATETIME` argument and returns a four-digit integer that represents the year.

The following example lists orders in which the `ship_date` is earlier than the beginning of the current year:

```
SELECT order_num, customer_num FROM orders
WHERE year(ship_date) < YEAR(TODAY);
```

Similarly, because a `DATE` value is a simple calendar date, you cannot add or subtract a `DATE` value with an `INTERVAL` value whose *last* qualifier is smaller than `DAY`. In this case, convert the `DATE` value to a `DATETIME` value.

## MONTHS\_BETWEEN Function

The `MONTHS_BETWEEN` function accepts two `DATE` or `DATETIME` expressions as arguments, and returns a signed `DECIMAL` value that quantifies the interval between those arguments in months, as if *month* were a unit of time.

This function requires two arguments, each of which can be a `DATE` expression or a `DATETIME` expression.

The value returned is a `DECIMAL` data type, representing the difference between the two arguments, expressed as a `DECIMAL` value based on 31-day units. If the first argument is a point in time later than the second argument, the sign of the returned value is positive. If the first argument is earlier than the second argument, the sign of the returned value is negative. If both arguments are equal, the return value is zero.

If the dates of the arguments are both the same days of a month or are both the last days of a months, the result is a whole number. Otherwise, the fractional portion of the result is calculated, based on a month of 31 days . This fractional part can also include the difference in *hour*, *minute*, and *second* time units, unless both arguments are DATE expressions.

The following query calls the **MONTHS\_BETWEEN** function in the Projection clause, using two DATE values returned by **TO\_DATE** expressions as arguments.

```
SELECT MONTHS_BETWEEN(TO_DATE('2-2-2005', '%m-%d-%Y'),
                     TO_DATE('1-1-2005', '%m-%d-%Y'))
AS lunations FROM systables WHERE tabid = 1;
```

The value returned by the query expresses the 32-day difference between the two DATE arguments as a positive number of 31-day months:

```
months
1.03225806451613
```

The next example returns the DATETIME column expression arguments to **MONTHS\_BETWEEN** expressions, and their differences in months for two rows of a table:

```
SELECT d_datetime, e_datetime,
       MONTHS_BETWEEN(d_datetime, e_datetime) AS months_between
FROM mytab1;
```

```
d_datetime      2007-11-01 09:00:00.00000
e_datetime      2007-12-07 14:30:12.12345
months_between  -1.2009453405018
```

```
d_datetime      2007-12-13 09:40:30.00000
e_datetime      2007-11-13 08:40:30.00000
months_between  1.000000000000000
```

Here the first **MONTHS\_BETWEEN** result includes differences in time units smaller than days. The second result has no fractional part, because the *day* time units of the arguments had the same value.

The **MONTHS\_BETWEEN** expressions in the next example compares DATE and DATETIME values:

```
SELECT col_datetime, col_date,
       MONTHS_BETWEEN(col_datetime, col_date) AS months_between
FROM mytab2;
```

```
col_datetime    2008-12-13 08:40:30.00000
col_date        11/13/2007
months_between  13.000000000000000
```

Because both arguments specify the same day of the month, the result has no fractional part.

## LAST\_DAY Function

The **LAST\_DAY** function requires a DATE or DATETIME expression as its only argument. It returns the date of the last day of the month that its argument specifies.

The data type of this returned value is the same data type as the argument. The difference between the returned value and the argument is the number of days remaining in that month.

The following query returns the DATE representation of the current date, the date of the last day in the current month, and the integer number of days (calculated by subtracting the first DATE value from second) before the last day in the current month:

```
SELECT TODAY AS today, LAST_DAY(TODAY) AS last,
       LAST_DAY(TODAY) - TODAY AS days_left
FROM systables WHERE tabid = 1;
```

If the query were issued on 12 March 2018, with `MDY4/` as the **DBDATE** setting for the default locale, it would return the following information:

| today      | last       | days_left |
|------------|------------|-----------|
| 03/12/2018 | 03/31/2018 | 19        |

In the SELECT statement of this example, there is no name conflict in the Projection clause between the TODAY operator and the identifier **today**, because the AS keyword indicates to Informix® that **today** is a display label.

If you use a host variable to store the argument to **LAST\_DAY**, but the data type of the argument is not known at prepare time, Informix® assumes that the data type is DATETIME YEAR TO FRACTION(5). If at runtime, after the statement has been prepared, the user supplies a DATE value for the host variable, error -9750 is issued. To prevent this error, specify the data type of the host variable by using a cast, as in this program fragment:

```
sprintf(query, ,
        select last_day(?:date) from mytab);
EXEC SQL prepare selectq from :query;
EXEC SQL declare select_cursor cursor for selectq;
EXEC SQL open select_cursor using :hostvar_date_input;

EXEC SQL fetch select_cursor into :var_date_output;
```

## NEXT\_DAY Function

The **NEXT\_DAY** function returns the earliest date that is later than its DATE or DATETIME first argument, and that falls on the day of the week that its second argument specifies. This second argument is a quoted string of three ASCII characters that abbreviates the English name of the day of the week.

The **NEXT\_DAY** function requires two arguments:

- a DATE or DATETIME expression that evaluates to a date earlier than the return value.
- a character string of at least three ASCII characters that correspond to upper case letters in the range from ASCII 65 through ASCII 90. These three letters encode the abbreviation English name for a day of the week.

Successful execution of this function returns the earliest calendar date that satisfies each of two conditions:

- The date is later than the date specified by the first argument.
- The date falls on the day of the week specified by the second argument.

**NEXT\_DAY** accepts the following abbreviation strings for days of the week:

**Table 27. Weekday abbreviations valid as arguments to the NEXT\_DAY function**

| Day of Week | Abbreviation | Day of Week | Abbreviation |
|-------------|--------------|-------------|--------------|
| Sunday      | 'SUN'        | Wednesday   | 'WED'        |
| Monday      | 'MON'        | Thursday    | 'THU'        |
| Tuesday     | 'TUE'        | Friday      | 'FRI'        |
|             |              | Saturday    | 'SAT'        |

Any characters that follow the 3rd character of these abbreviation strings are ignored. For example, both 'MONDAY' and 'MONTAG' are valid specification for the 2nd argument, each specifying the next Monday after the date in the first argument. Informix® issues an error, however, if the second argument is a string such as 'MODNAY' whose first three characters do not match one of the *weekday* abbreviations in the table above.

The following query, for example, includes a valid **NEXT\_DAY** expression:

```
SELECT ship_date, NEXT_DAY(ship_date, 'SAT') AS next_saturday,
       NEXT_DAY(ship_date, 'SAT') - ship_date AS num_days FROM orders;
```

The result set of this query might include the following data from the **orders** table:

```
ship_date  next_saturday  num_days
06/01/2006 06/03/2006      2
02/12/2007 02/17/2007      5
05/31/2007 06/02/2007      2
05/23/2007 05/26/2007      3
```

The value returned by **NEXT\_DAY** has the same data type as the first argument. If this argument is a DATE type, **NEXT\_DAY** returns a DATE value. If the first argument is a DATETIME type, **NEXT\_DAY** returns a DATETIME YEAR TO FRACTION(5) value.

Because **ship\_date** in the preceding example is a DATE column, the returned dates are formatted as DATE values, rather than in DATETIME format.

If you use a host variable to store the argument to **NEXT\_DAY**, but the data type of the argument is not known at prepare time, Informix® assumes that the data type is DATETIME YEAR TO FRACTION(5). If at runtime, after the statement has been prepared, the user supplies a DATE value for the host variable, error -9750 is issued. To prevent this error, specify the data type of the host variable by using a cast, as in this program fragment:

```
sprintf(query, ,
        select next_day(?::date, 'SUN') from mytab);
EXEC SQL prepare selectq from :query;
EXEC SQL declare select_cursor cursor for selectq;
```

```
EXEC SQL open select_cursor using :hostvar_date_input;
EXEC SQL fetch select_cursor into :var_date_output;
```

## EXTEND Function

The **EXTEND** function adjusts the precision of a DATETIME or DATE value.

The DATETIME or DATE expression that is its first argument cannot be a quoted string representation of a DATE value.

If you do not specify *first* and *last* qualifiers, the default qualifiers are YEAR TO FRACTION(3).

If the expression contains fields that are not specified by the time-unit qualifiers, those fields are discarded.

If the *first* qualifier specifies a larger (that is, more significant) time unit than what exists in the expression, the new fields are filled in with values returned by the **CURRENT** function. If the *last* qualifier specifies a smaller time unit (that is, less significant) than what exists in the expression, the new fields are filled in with constant values. A missing MONTH or DAY field is filled in with 1, and the missing HOUR to FRACTION fields are filled in with 0.

In the following expression, the **EXTEND** call returns the **call\_dtime** column value with YEAR TO SECOND precision:

```
EXTEND (call_dtime, YEAR TO SECOND)
```

You can use the **EXTEND** function to perform addition or subtraction with a DATETIME value and an INTERVAL value that do not have the same time unit qualifiers. The next expression expands a literal DATETIME YEAR TO DAY value to a precision of YEAR TO MINUTE so that an interval YEAR TO MINUTE value can be subtracted from it:

```
EXTEND (DATETIME (2009-8-1) YEAR TO DAY, YEAR TO MINUTE)
- INTERVAL (720) MINUTE (3) TO MINUTE
```

You can use the **EXTEND** function to selectively update a subset of the time units in a DATETIME value. The UPDATE statement in the next example updates only the *hour* and *minute* time unit values in a DATETIME YEAR TO MINUTE column.

```
UPDATE cust_calls SET call_dtime = call_dtime -
  (EXTEND(call_dtime, HOUR TO MINUTE) - DATETIME (11:00)
  HOUR TO MINUTE) WHERE customer_num = 106;
```

Subtracting 11:00 from the DATETIME HOUR TO MINUTE value returned by **EXTEND** yields a positive or negative INTERVAL HOUR TO MINUTE value. Subtracting this difference from the original value in the **call\_dtime** column forces the updated *hour* and *minute* time unit values to 11:00 in the **cust\_calls.call\_dtime** column.

## MDY Function

The **MDY** function takes as its arguments three integer expressions that represent the *month*, *day*, and *year*, and returns a type DATE value.

- The first argument represents the number of the month (1 to 12).
- The second argument represents the number of the day of the month (1 to 28, 29, 30, or 31, as appropriate for the month).
- The third argument represents the 4-digit year. You cannot use a 2-digit abbreviation.

### Example of the MDY function in an UPDATE statement

The following example updates a row in the **orders** table whose purchase-order number is 8052 by changing its **paid\_date** column value to the first day of the current month:

```
UPDATE orders SET paid_date = MDY(MONTH(TODAY), 1, YEAR(TODAY))
WHERE po_num = '8052';
```

Here the first and last arguments to the **MDY** function are time expressions that return integers corresponding to the current *month* and *year*. The second argument specifies the *day of the month* as a literal integer. Reversing the order of the first two arguments in this example would change the **paid\_date** value to some day before January 13 of the current year, unless the same application also included error-checking code that identified that date as too early to be valid.

## TO\_CHAR Function

The **TO\_CHAR** function converts an expression that evaluates to a DATE, DATETIME, or numeric value to a character string.

The returned character string represents the data value that the first argument specifies, using a formatting mask that the second argument defines in a *format\_string* that can include special formatting symbols and literal characters.

- The first argument to this function must be of a DATE, DATETIME, or built-in numeric data type, or a character string that can be converted to one of these data types. If the value of the initial DATE, DATETIME, or numeric argument is NULL, the function returns a NULL value.
- The second argument to this function is a character string that specifies a formatting mask. What set of special characters is appropriate for the formatting mask primarily depends on whether the first argument to the **TO\_CHAR** function represents a point in time or a number.

### Formatting DATE and DATETIME expressions

The *format\_string* argument does not need to imply the same time units as the value in the first argument to the **TO\_CHAR** function. When the precision implied in the *format\_string* is different from the DATETIME qualifier in the first argument, the **TO\_CHAR** function extends the DATETIME value as if it had called the **EXTEND** function.

In the following example, the user wants to convert the **begin\_date** column of the **tab1** table to a character string. The **begin\_date** column is defined as a DATETIME YEAR TO SECOND data type. The user uses a SELECT statement with the **TO\_CHAR** function to perform this conversion:

```
SELECT TO_CHAR(begin_date, '%A %B %d, %Y %R') FROM tab1;
```

The symbols in the *format\_string* of this example have the following meanings.

#### Symbol

#### Meaning

**%A**

Full weekday name, as defined in the locale

**%B**

Full month name, as defined in the locale

**%d**

Day of the month as an integer (01 through 31). A single-digit value is preceded by a zero (0).

**%Y**

Year as a 4-digit decimal number

**%R**

Time in 24-hour notation (equivalent to `%H:%M` format, as defined below).

Note that the comma ( , ) that immediately follows the `%d` format specification in the example above is a literal character, rather than a separator of arguments to the **TO\_CHAR** function. The second argument is the quoted string `'%A %B %d, %Y %R'` that defines the formatting mask for representing the first argument in the value that **TO\_CHAR** returns.

Applying this *format\_string* to the **begin\_date** column value returns this result:

```
Wednesday July 25, 2013 18:45
```

The query in the next example calls **TO\_CHAR** to apply the same format string to an **ADD\_MONTHS** expression, and shows the results of the query:

```
SELECT ship_date, TO_CHAR(ADD_MONTHS(ship_date, 1), '%A %B %d, %Y')
AS survey_date FROM orders;

ship_date      03/12/2013
survey_date    Thursday April 12, 2013
```

In the query output above,

- the **ship\_date** value is formatted according to the **DB\_DATE** environment variable setting,
- and the **survey\_date** value is formatted according to the `'%A %B %d, %Y %R'` formatting string argument to the **TO\_CHAR** function.

Additional symbols that are valid in the *format\_string* argument to the **TO\_CHAR** function for DATE or DATETIME values include the following.

**Symbol****Meaning****%a**

Abbreviated weekday name, as defined in the locale

**%b**

Abbreviated month name, as defined in the locale

**%C**

The century number (the year divided by 100 and truncated to an integer) as an integer (00 through 99)

**%D**

The same as the `%m/%d/%y` format

**%e**

Day of the month as a number (1 through 31). A single-digit value is preceded by a blank space.

**%Fn**

The value of the fraction of a second, with precision specified by the unsigned integer n. The default value of n is 2; the range of n is 0 n 5. This value overrides any width or precision that is specified between the `%` and `F` characters.

**%h**

Same as the `%b` format: abbreviated month name, as defined in the locale

**%H**

Hour as a 2-digit integer (00 through 23) (24-hour clock)

**%I**

Hour as a 2-digit integer (00 through 11) (12-hour clock)

**%m**

Month as an integer (01 through 12). Any single-digit value is preceded by a zero (0).

**%M**

Minute as a 2-digit integer (00 through 59)

**%S**

Second as a 2-digit integer (00 through 61). The second value can be up to 61 (instead of 59) to allow for the occasional leap second and double leap second.

**%T**

Time in the `%H:%M:%S` format

**%w**

Weekday as a number (0 through 6); 0 represents the locale equivalent of Sunday.

**%y**

Year as a 2-digit decimal number.

For example, suppose that on August 23, 2013, the DB-Access facility issued the following query:

```
SELECT TO_CHAR(CURRENT YEAR TO FRACTION(5), "%Y-%m-%d %H:%M:%S.%F")
FROM sysmaster:sysdual;
```

In this example, the format string argument specifies a user format with the following literal characters as separators between the DATETIME field values:

- ASCII 45 ( - ) hyphen to separate the year, month, and day values
- ASCII 32 ( ) blank to separate the day from the hour
- ASCII 58 ( : ) colon to separate the hour, minute, and seconds
- ASCII 46 ( . ) period to separate the second from the fraction of a second.

This is the returned value in the specified DATETIME user format:

```
(expression) 2013-08-23 13:15:53.00
```

If you omit the *format\_string* argument when a DATETIME or DATE expression is the first argument, the **TO\_CHAR** function uses as a default the setting of the **DBTIME** or **DBDATE** environment variables to format the value represented in the first argument. In nondefault locales, the default format for DATETIME and DATE values is specified by environment variables such as **GL\_DATETIME** and **GL\_DATE**.

**Important:** For DATETIME user formats whose precision includes both SECOND and FRACTION data values, those fields are concatenated unless a separator character is explicitly defined between the **%S** and **%F** formatting directives. In version 11.70.xC7 and earlier Informix® releases, the **%F** directive inserted the ASCII 46 character ( . ) by default between the SECOND and FRACTION field values. In this release, however, the **%F** directive implies no default separator.

For the order of precedence among the Informix® environment variables that can specify the display and data entry formats for the built-in chronological data types, see the topic [Precedence of DATE and DATETIME format specifications on page 1416](#).

## Formatting numeric and MONEY expressions

The *format\_string* argument to the **TO\_CHAR** function supports the same numeric formatting masks that are used for ESQL functions like **rfmtdec()**, **rfmtdouble()**, and **rfmtlong()**. A detailed description of the Informix® numeric-formatting masks for numeric values (when formatting numeric expressions as strings) is in the *Informix® ESQL/C Programmer's Manual*. Below is a short summary description of the numeric formatting masks.

A numeric-formatting mask specifies a format to apply to some numeric value when formatting a numeric expression as a string. This mask is a combination of the following formatting characters:

### Symbol

#### Meaning

\*

This character fills with asterisks any positions in the display field that would otherwise be blank

**&**

This character fills with zeros any positions in the display field that would otherwise be blank

**#**

This character changes leading zeros to blanks. Use this character to specify the maximum leftward extent of a field.

**<**

This character left-justifies the numbers in the display field. It changes leading zeros to a NULL string.

**,**

This character indicates the symbol that separates groups of three digits (counting leftward from the units position) in the whole-number part of the value. By default, this symbol is a comma. You can set the symbol with the **DBMONEY** environment variable. In a formatted number, this symbol appears only if the integer part of the value has four or more digits.

**.**

This character indicates the symbol that separates the integer part of a money value from the fractional part. By default, this symbol is a period. You can set the symbol with the **DBMONEY** environment variable. You can have only one period in a format string.

**-**

This character is a literal. It appears as a minus sign when *expr1* is less than zero. When you group several minus ( - ) signs in a row, a single minus sign floats to the rightmost position that it can occupy; it does not interfere with the number and its currency symbol.

**+**

This character is a literal. It appears as a plus sign when *expr1* is greater than or equal to zero, and as a minus sign when *expr1* is less than zero. When you group several plus signs in a row, a single plus or minus sign floats to the rightmost position that it can occupy; it does not interfere with the number and its currency symbol.

**(**

This character is a literal. It appears as a left parenthesis ( ( ) to the left of a negative number. It is one of the pair of accounting parentheses that replace a minus sign for a negative number. When you group several in a row, a single left parenthesis floats to the rightmost position that it can occupy; it does not interfere with the number and its currency symbol.

**)**

This is one of the pair of accounting parentheses that replace a minus sign for a negative value.

**\$**

This character displays the currency symbol that precedes the numeric value. In the default locale, the currency symbol is the dollar sign (\$). You can set a nondefault currency symbol with the **DBMONEY** environment variable. When you group several dollar signs in a row, a single currency symbol floats to the rightmost position that it can occupy; it does not interfere with the number.

Any other characters in the formatting mask are reproduced literally in the formatted value that the **TO\_CHAR** function returns.

In the next three examples, the value of the **d\_int** column expression argument to the **TO\_CHAR** function is `-12344455`.

This query specifies no formatting mask in a call to **TO\_CHAR**:

```
SELECT TO_CHAR(d_int) FROM tab_numbers;
```

The following table shows the output of this SELECT statement.

| (expression) |
|--------------|
| -12344455    |

The following query specifies a monetary format mask:

```
SELECT TO_CHAR(d_int, "$*****.**") FROM tab_numbers;
```

The following table shows the output of this SELECT statement.

| (expression)  |
|---------------|
| \$12344455.00 |

```
SELECT TO_CHAR(d_int, "-$*****.**") FROM tab_numbers;
```

The query returns `- $12344455.00`.

```
SELECT TO_CHAR(12344455, "-$*****.**") FROM tab_numbers;
```

The following table shows the output of this SELECT statement.

| (constant)    |
|---------------|
| \$12344455.00 |

The currency ( \$ ) symbol from the formatting mask argument is applied, but the minus ( - ) symbol has no effect, because the value of the first argument is greater than zero.

Note that the **TO\_CHAR** function is a time expression only when its first argument is a DATE or DATETIME expression, or is a character string that can be formatted as a DATE or DATETIME expression. When a numeric or monetary value is its first argument, however, **TO\_CHAR** returns a representation of the value of that argument as a character string, but it does not return a time expression.

## TO\_DATE Function

The **TO\_DATE** function converts a character string to a DATETIME value. The function evaluates the *char\_expression* first argument as a date, according to the date format that the *format\_string* second argument specifies, and returns the equivalent date.

If *char\_expression* is NULL, then a NULL value is returned.

Any argument to the **TO\_DATE** function must be of a built-in data type.

If you omit the *format\_string* parameter, the **TO\_DATE** function applies the default DATETIME format to the DATETIME value. The default DATETIME format is specified by the **GL\_DATETIME** environment variable.

In the following example, the user wants to convert a character string to a DATETIME value in order to update the **begin\_date** column of the **tab1** table with the converted value. The **begin\_date** column is defined as a DATETIME YEAR TO SECOND data type. The user uses an UPDATE statement that contains a **TO\_DATE** function to accomplish this result:

```
UPDATE tab1
  SET begin_date = TO_DATE('Wednesday July 25, 2007 18:45',
    '%A %B %d, %Y %R');
```

The *format\_string* parameter in this example tells the **TO\_DATE** function how to format the converted character string in the **begin\_date** column. For a table that shows the effect of each format symbol in this format string, see [TO\\_CHAR Function on page 1314](#).

## TO\_NUMBER Function

The **TO\_NUMBER** function can convert a number or a character expression representing a number value to a DECIMAL data type.

The **TO\_NUMBER** function has this syntax:

TO\_NUMBER Function

```
TO_NUMBER(
  char_expr num_expr
)
```

| Element                | Description                                   | Restrictions   | Syntax                                  |
|------------------------|---|--|---|
| <i>char_expression</i> | Expression to be converted to a DECIMAL value | Must be a literal, host variable, expression, or column of a character data type | <a href="#">Expression on page 1193</a> |
| <i>num_expression</i>  | Expression that evaluates to a real number    | Must return a numeric data type  | <a href="#">Expression on page 1193</a> |

The **TO\_NUMBER** function converts its argument to a DECIMAL data type. The argument can be the character string representation of a number or a numeric expression.

The following example retrieves a DECIMAL value that the **TO\_NUMBER** function returns from the literal representation of a MONEY value:

```
SELECT TO_NUMBER('$100.00') from mytab;
```

The following table shows the output of this SELECT statement.

---

**(expression)**

---

100.00000000000000

---

In this example, the currency symbol is discarded from the '\$100.00' string.

The **TO\_NUMBER** function is not required in most contexts, because by default, Informix® converts numbers that include a decimal point (and quoted strings in the format of a literal number that has a decimal point) to a DECIMAL data type. This function can be useful, however, when you are migrating SQL applications that were originally written for other database servers, if the application makes calls to a function of this name that returns a DECIMAL value.

## Trigonometric Functions

The built-in trigonometric functions calculate ratios of the lengths of the sides of right triangles. Two supporting functions, **DEGREES** and **RADIANS**, can respectively convert the units of angular values from radians to degrees, and from degrees to radians.

The built-in trigonometric functions have the following syntax.

Trigonometric Functions

**COS COSH SIN SINH TAN TANH DEGREES**

(*radian\_expr*)

**ASIN ASINH ACOS ACOSH ATAN ATANH**

(*numeric\_expr*)

**ATAN2**(*y*, *x*)

**RADIANS** (*degree\_expr*)

| Element             | Description   | Restrictions  | Syntax                                  |
|---------------------|---|---|---|
| <i>degree_expr</i>  | Expression that represents the number of degrees  | Must return a value that can be converted to a DECIMAL type | <a href="#">Expression on page 1193</a> |
| <i>numeric_expr</i> | Expression that serves as the argument to the <b>ASIN</b> , <b>ACOS</b> , <b>ATAN</b> , <b>ASINH</b> , <b>ACOSH</b> or <b>ATANH</b> functions | Must return a value between -1 and 1, inclusive             | <a href="#">Expression on page 1193</a> |
| <i>radian_expr</i>  | Expression that represents the number of radians  | Must return a numeric value                                 | <a href="#">Expression on page 1193</a> |
| <i>x</i>            | Expression that represents the x coordinate in the rectangular coordinate pair ( <i>x</i> , <i>y</i> )  | Must return a numeric value                                 | <a href="#">Expression on page 1193</a> |

| Element | Description   | Restrictions                | Syntax                                  |
|---------|---|-----------------------------|---|
| y       | Expression that represents the y coordinate in the rectangular coordinate pair (x, y) | Must return a numeric value | <a href="#">Expression on page 1193</a> |

Sections that follow describe each of these built-in trigonometric functions.

## COS Function

The **COS** function returns the cosine of a radian expression.

The following example returns the cosine of the values of the degrees column in the **anglestbl** table. The expression passed to the **COS** function in this example converts degrees to radians.

```
SELECT COS(degrees*180/3.1416) FROM anglestbl;
```

## COSH function

The **COSH** function returns the hyperbolic cosine of the required argument, where the argument is an angle expressed in radians.

COSH function

**COSH**(*radian\_expr*)

| Element            | Description   | Restrictions                   | Syntax                                  |
|--------------------|---|--------------------------------|---|
| <i>radian_expr</i> | Expression that evaluates to an angular value in units of radians | Must be of a numeric data type | <a href="#">Expression on page 1193</a> |

The following example returns the hyperbolic cosine of the values in the degrees column of the **anglestbl** table. The expression passed to the **COSH** function converts the degrees to radians.

```
SELECT COSH(degrees*180/3.1416) FROM anglestbl;
```

## SIN Function

The **SIN** function returns the sine of an angle that you specify as its radian expression argument.

The following query returns the sines of the values in each row of the **radians** column of the **anglestbl** table:

```
SELECT SIN(radians) FROM anglestbl;
```

## SINH function

The **SINH** function returns the hyperbolic sine of the argument, where the argument is an angle expressed in radians.

SINH Function

**SINH**(*radian\_expr*)

The following example returns the hyperbolic sine of the values in the degrees column of the **anglestbl** table. The expression passed to the SINH function converts the degrees to radians.

```
SELECT SINH(degrees*180/3.1416) FROM anglestbl;
```

## TAN Function

The **TAN** function returns the value of the tangent of its radian expression argument.

This example returns the tangent of the values in the **radians** column of the **anglestbl** table:

```
SELECT TAN(radians) FROM anglestbl;
```

## TANH Function

The **TANH** function returns the hyperbolic tangent of the argument, where the argument is an angle expressed in radians.

TANH Function

**TANH**(*radian\_expr*)

The following example returns the hyperbolic tangent of the values in the degrees column of the **anglestbl** table. The expression passed to the TANH function converts the degrees to radians.

```
SELECT TANH(degrees*180/3.1416) FROM anglestbl;
```

## ACOS Function

The **ACOS** function returns the arc cosine of a numeric expression.

The following example returns the arc cosine of the value (-0.73) in radians:

```
SELECT ACOS(-0.73) FROM anglestbl;
```

## ACOSH Function

The **ACOSH** function returns the hyperbolic tangent of the specified numeric input.

ACOSH Function

**ACOSH**(*numeric\_expr*)

## ASIN Function

The **ASIN** function returns the arc sine of a numeric expression argument.

The following example returns the arc sine of the value (-0.73) in radians:

```
SELECT ASIN(-0.73) FROM anglesTbl;
```

## ASINH Function

The ASINH function returns the arc hyperbolic sine of the specified numeric input.

ASINH Function

**ASINH**(numeric\_expr)

## ATAN Function

The **ATAN** function returns the arc tangent of a numeric expression.

The following example returns the arc tangent of the value (-0.73) in radians:

```
SELECT ATAN(-0.73) FROM anglesTbl;
```

## ATANH Function

The ATANH function returns the hyperbolic tangent of the specified numeric input.

ATANH Function

**ATANH**(numeric\_expr)

## ATAN2 Function

The **ATAN2** function computes the angular component of the polar coordinates ( $r$ ,  $q$ ) associated with ( $x$ ,  $y$ ).

The following example compares *angles* to  $q$  for the rectangular coordinates (4, 5):

```
WHERE angles > ATAN2(4,5)    --determines q for (4,5) and
                             --compares to angles
```

You can determine the length of the radial coordinate  $r$  using the expression that the following example shows:

```
SQRT(POW(x,2) + POW(y,2))    --determines r for (x,y)
```

You can determine the length of the radial coordinate  $r$  for the rectangular coordinates (4,5) using the expression that the following example shows:

```
SQRT(POW(4,2) + POW(5,2))    --determines r for (4,5)
```

## DEGREES function

Use the **DEGREES** function to convert the value of an expression or host variable representing a number of radians to the equivalent number of degrees.

The *radian\_expression* or host variable that is the only argument to this function must be a numeric data type (or a non-numeric data type that can be converted to a number) that the database server evaluates in units of radians, and converts to units of degrees.

The return value is a number of type DECIMAL (32, 255).

In both of the examples that follow, the argument to **DEGREES** evaluates to 6 radians, and the return value is 343.774677078494 degrees:

```
EXECUTE FUNCTION DEGREES (6);
EXECUTE FUNCTION DEGREES ("6");
```

The **DEGREES** function converts radians to degrees according to the following formula:

$$(\text{number of radians}) * (180/\pi) = (\text{number of degrees})$$

Here **pi** represents the ratio of the circumference of a circle to its diameter. Results of arithmetic calculations that use the transcendental number **pi** as the divisor of a rational number always include rounding error.

## RADIANS function

Use the **RADIANS** function to convert an expression or a host variable representing a number of degrees to the equivalent number of radians.

The return value is a number of type DECIMAL (32, 255).

The *degree\_expression* that is the only argument to this function must have a numeric data type (or a non-numeric data type that can be converted to a number) that the database server evaluates in units of degrees, and converts to units of radians:

```
EXECUTE FUNCTION RADIANS (100);
EXECUTE FUNCTION RADIANS ("100");
```

In both of the examples above, the **RADIANS** argument evaluates to 100 degrees, and the return value is 1.745328251994 radians. You can use a **RADIANS** function expression as the argument to the **COS**, **SIN**, or **TAN** function to return the respective trigonometric values for that angle:

```
COS(RADIANS (100))
SIN(RADIANS ("100"))
TAN(RADIANS (100))
```

The **RADIANS** function converts degrees to radians according to the following formula:

```
(number of degrees) * (pi/180) = (number of radians)
```

Here **pi** represents the ratio of the circumference of a circle to its diameter. Results of arithmetic calculations that use the transcendental number **pi** as the dividend of a rational number always include rounding error.

## String-Manipulation Functions

String-manipulation functions perform various operations on strings of characters.

The string-manipulation functions are identified in the following diagram:

## String-Manipulation Functions

CONCAT Function<sup>611</sup>ASCII Function<sup>608</sup>TRIM Function<sup>599</sup>  
598LTRIM Function<sup>606</sup>  
598RTRIM Function<sup>607</sup>SPACE Function<sup>601</sup>REVERSE Function<sup>610</sup>  
598REPLACE Function<sup>602</sup>  
598LPAD Function<sup>603</sup>  
598RPAD Function<sup>604</sup>CHR Function<sup>609</sup>  
598Case-Conversion Functions<sup>605</sup>Substring Functions<sup>600</sup>

Sections that follow describe each of the built-in string manipulation functions.

598. Informix® extension

See [CONCAT Function on page 1327](#)

## CONCAT Function

The **CONCAT** function accepts two expressions as arguments, and returns a single character string that appends the string representation of the value returned by its second argument to the string representation of the value returned by its first argument.

CONCAT Function

**CONCAT**(*expr\_1*, *expr\_2*)

| Element                          | Description   | Restrictions   | Syntax                                  |
|----------------------------------|---|--|---|
| <i>expr_1</i> ,<br><i>expr_2</i> | Expressions whose string representations of their values are to be concatenated | Cannot return a complex, user-defined, or large object type. If a host variable, it must be long enough to store the resulting combined strings. | <a href="#">Expression on page 1193</a> |

Each arguments to the **CONCAT** function can evaluate to a character, number, or time data type. If either or both of the concatenated arguments is null, the function returns a NULL value.

Unlike other built-in string manipulation functions of Informix®, the **CONCAT** function cannot be overloaded.

**CONCAT** is the operator function of the concatenation ( || ) operator. For a given pair of expression arguments, **CONCAT** returns the same string as that operator returns from the same expressions as operands. See [Concatenation Operator on page 1215](#) for additional information about concatenation operations, and for restrictions on the SQL and Dynamic SQL statements in which you can invoke the **CONCAT** function.

## Return Types from CONCAT and String Functions

The data type of the return value from a successful call to the **CONCAT** function (or from the concatenation ( || ) operator, or from a call to other built-in string-manipulation functions that follow the same rules as **CONCAT** for determining their return type) depends on the data types of the arguments and on the length of the resulting string. The order of the two arguments is not significant in determining the return type.

Informix® applies the following rules for the return type from operations that concatenate values that arguments of more than one data type specify:

- If one of the types is National Language Support (namely NCHAR and NVARCHAR):
  - the return type is NVARCHAR if the resulting length is less than 255 bytes
  - the return type is NCHAR otherwise.
- If one of the arguments is VARCHAR or a number type,
  - the return type is VARCHAR if the resulting length is less than 255 bytes
  - the return type is LVARCHAR otherwise.
- An exception to these rules, however, can occur in certain cross-server operations in which a remote routine is executed locally, and a concatenation expression is evaluated locally before its return value is sent to a remote

database server. For remote servers that do not support the LVARCHAR data type in distributed transactions, the concatenated result is sent as a CHAR data type if sending the LVARCHAR type returns an error. Informix® database server instances earlier than Version 11.10 require a CHAR return value in this scenario.

In the following table, the rows list the valid data types of the first argument to the **CONCAT** function, and the columns list the type of the second argument. The cell at the intersection of each row and column shows the possible returned type or types. The row and the column labelled as **Other** represent arguments that evaluate to non-character types, such as number or time data types like DECIMAL or DATE.

**Table 28. Return Types from Operations on Two Arguments (in Version 11.50.xC2 or Later)**

|                      | <b>NCHAR</b>         | <b>NVARCHAR</b>      | <b>CHAR</b>            | <b>VARCHAR</b>         | <b>LVARCHAR</b>      | <b>Other</b>           |
|----------------------|----------------------|----------------------|------------------------|------------------------|----------------------|------------------------|
| <b>NCHAR</b>         | nchar                | nvarchar or<br>nchar | nchar                  | nvarchar or nchar      | nvarchar or<br>nchar | nvarchar or nchar      |
| <b>NVARCHA<br/>R</b> | nvarchar or<br>nchar | nvarchar or<br>nchar | nvarchar or nchar      | nvarchar or nchar      | nvarchar or<br>nchar | nvarchar or nchar      |
| <b>CHAR</b>          | nchar                | nvarchar or<br>nchar | char                   | varchar or<br>lvarchar | lvarchar             | varchar or<br>lvarchar |
| <b>VARCHAR</b>       | nvarchar or<br>nchar | nvarchar or<br>nchar | varchar or<br>lvarchar | varchar or<br>lvarchar | lvarchar             | varchar or<br>lvarchar |
| <b>LVARCHA<br/>R</b> | nvarchar or<br>nchar | nvarchar or<br>nchar | lvarchar               | lvarchar               | lvarchar             | lvarchar               |
| <b>Other</b>         | nvarchar or<br>nchar | nvarchar or<br>nchar | varchar or<br>lvarchar | varchar or<br>lvarchar | lvarchar             | varchar or<br>lvarchar |

For string manipulation functions other than **CONCAT**, arguments of DATE, DATETIME, or MONEY data types always return an NVARCHAR or NCHAR value, depending on the length of the resulting string.

This table is symmetrical, because the order of arguments has no affect on the return data type. User-defined data types, large-object types, complex types, and other extended data types are not valid as arguments to the built-in string-manipulation functions or operators.

This table also describes the return data types of expressions that use the concatenation ( || ) operator.

Not shown here is the result of concatenation operations in which the sum of the argument lengths exceeds the approximately 32Kb limit for CHAR, NCHAR, and LVARCHAR data types. This returns error -881, rather than a concatenated data value. Because the maximum LVARCHAR size is 32,739 bytes, and the CHAR and NCHAR limits are both 32,767 bytes, error -881 is usually associated with VARCHAR and NVARCHAR objects, whose limit is 255 bytes, but automatic return type promotion can reduce the incidence of this error.

The following string-manipulation functions support the same rules as **CONCAT** for return type promotion:

- **LPAD**
- **RPAD**

- REPLACE
- SUBSTR
- SUBSTRING
- TRIM
- LTRIM
- RTRIM

The following table summarizes how Informix® determines the return type from these string manipulating functions, based on the argument types:

**Table 29. String Manipulation Functions that Support Return Type Promotion**

| Function  | How the Return Type of the Function is Determined   |
|---|---|
| <b>CONCAT,   </b>   | Return type is based on both arguments. Refer to <a href="#">Table 28: Return Types from Operations on Two Arguments (in Version 11.50.xC2 or Later)</a> on page 1329..   |
| <b>SUBSTR, SUBSTRING</b>  | Return type is the same as the <i>source string</i> type. If <i>source string</i> is a host variable, the return type is NVARCHAR or NCHAR, depending on the length of the result.  |
| <b>TRIM, LTRIM, RTRIM</b>   | Return type depends on the source type and the returned length: <ul style="list-style-type: none"> <li>• NVARCHAR <i>returns</i> NVARCHAR</li> <li>• VARCHAR <i>returns</i> VARCHAR</li> <li>• CHAR <i>returns</i> VARCHAR (if length &lt;= 255 bytes)</li> <li>• CHAR <i>returns</i> LVARCHAR (if length &gt; 255 bytes)</li> <li>• NCHAR <i>returns</i> NVARCHAR (if length &lt;= 255 bytes)</li> <li>• NCHAR <i>returns</i> LVARCHAR (if length &gt; 255 bytes)</li> <li>• LVARCHAR <i>returns</i> LVARCHAR</li> </ul> |
| <b>LPAD, RPAD</b>   | Return type is based on the <i>source_string</i> and <i>pad_string</i> arguments. If <i>pad_string</i> is not specified, the return type is based on the data type of <i>source_string</i> .  |
| <b>REPLACE</b>  | Return type is based on the <i>source_string</i> and <i>old_string</i> arguments (and on the <i>new_string</i> argument, if that is specified). If any argument is a host variable, the return type is NCHAR.   |
| <b>ENCRYPT_AES,<br/>ENCRYPT_TDES,<br/>DECRYPT_BINARY,<br/>DECRYPT_CHAR,</b> | For arguments that are not BLOB or CLOB variables, the return type is based on the data types of the <i>data</i> and <i>encrypted_data</i> arguments. Refer to <a href="#">Table 28: Return Types from Operations on Two Arguments (in Version 11.50.xC2 or Later)</a> on page 1329.  |

## Data-type promotion in NLSCASE INSENSITIVE databases

In databases that have the NLSCASE INSENSITIVE property, the database server disregards the lettercase of NCHAR and NVARCHAR values. Expressions in which functions or operators avoid overflow errors by performing an implicit cast can

produce different results from what a case-sensitive database would return, if the expression evaluates to an NCHAR or NVARCHAR data type.

When a string function or a string operator on which the database server supports data-type promotion returns a value that would produce an overflow error for the default VARCHAR or NVARCHAR data type of the expression, the database server performs an implicit cast on the return value, as indicated in the first table of the topic [Return Types from CONCAT and String Functions on page 1328](#):

- If the none of the arguments or operands are NCHAR or NVARCHAR data types, the expression evaluates to a CHAR, LVARCHAR, or VARCHAR data type.
- If any argument or operand is an NCHAR or NVARCHAR data type, the expression evaluates to an NCHAR or NVARCHAR data type.

In databases that have the NLSCASE INSENSITIVE property, operations on CHAR, LVARCHAR, or VARCHAR data types are case-sensitive, but operations on NCHAR or NVARCHAR data types are case-insensitive. Data-type promotion also produces case-insensitive results (rather than case-sensitive) from evaluating an expression that includes CHAR, LVARCHAR, or VARCHAR components, if the same expression also includes NCHAR or NVARCHAR character strings.

The following example illustrates this behavior in a NLSCASE INSENSITIVE database, in which table **t1** has a character column of each of the five built-in character data types. The table stores three rows, in which each column stores the same lettercase variants of a 3-letter character string:

```
CREATE DATABASE db NLSCASE INSENSITIVE;
CREATE TABLE t1 (
  c1 NCHAR(20),
  c2 NVARCHAR(20),
  c3 CHAR((20),
  c4 VARCHAR(20),
  c5 LVARCHAR(20)) ;
INSERT INTO t1 values ('ibm', 'ibm', 'ibm', 'ibm', 'ibm');
INSERT INTO t1 values ('Ibm', 'Ibm', 'Ibm', 'Ibm', 'Ibm');
INSERT INTO t1 values ('IBM', 'IBM', 'IBM', 'IBM', 'IBM');
```

The following query retrieves the values from an NCHAR column, using an equality predicate for a literal string whose letters are all lowercase:

```
SELECT c1 FROM t1 WHERE c1 = 'ibm';
```

Because NCHAR values are not case sensitive in this database, the query returns the column **c1** value from every row:

```
c1
ibm
Ibm
IBM
```

The following query on the same table returns the same case-insensitive results from CHAR column **c3** that the WHERE clause casts to an NCHAR value:

```
SELECT c1 FROM t1 WHERE c3 = 'ibm'::NCHAR(10);
```

After the cast, the **c3** values become case insensitive, so that every row in **c3** matches the string `'ibm'`, and the WHERE condition is true for every row in **c1** :

```
c1
ibm
Ibm
IBM
```

Because case-insensitive operations disregard differences in letter case among strings where the same letters appear in the same sequence, as in the previous example, care must be taken in databases that have the NLSCASE INSENSITIVE property to avoid contexts where data type-promotion applies case-insensitive rules to operations that you expected to be case sensitive.

See also the section [Duplicate rows in NLSCASE INSENSITIVE databases on page 779](#).

## Return String Types in Distributed Transactions

In cross-database distributed queries that access tables in different databases of the same Informix® instance, the same types are returned by **CONCAT** (and by other built-in string manipulation functions that follow the same rules for return type promotion) that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The same types are also returned in cross-server distributed queries, if every participating Informix® instance that evaluates these string-manipulation function expressions is no earlier than Version 11.50.xC2.

For cross-server distributed operations in which the return value is evaluated on a remote Informix® instance earlier than Version 11.50.xC2, the following table (in the same format as the table for Version 11.50.xC2 and later) lists the possible return data types (or -881 overflow error) for the specified data types of arguments to the string-manipulation function (or for operands of the concatenation ( || ) operator):

**Table 30. Return Types from Distributed Operations (in Version 11.50.xC1 and earlier)**

|                      | <b>NCHAR</b>        | <b>NVARCHAR</b>        | <b>CHAR</b>            | <b>VARCHAR</b>         | <b>LVARCHAR</b>        | <b>Other</b>           |
|----------------------|---------------------|------------------------|------------------------|------------------------|------------------------|------------------------|
| <b>NCHAR</b>         | nchar               | nvarchar or EM<br>-881 | nchar                  | nchar                  | nchar                  | nchar                  |
| <b>NVARCHA<br/>R</b> | nchar or EM<br>-881 | nvarchar or EM<br>-881 |
| <b>CHAR</b>          | nchar               | nvarchar or EM<br>-881 | char                   | varchar or EM<br>-881  | char                   | char                   |
| <b>VARCHAR</b>       | nchar               | nvarchar or EM<br>-881 | varchar or EM<br>-881  | varchar or EM<br>-881  | varchar or EM<br>-881  | varchar or EM<br>-881  |
| <b>LVARCHA<br/>R</b> | nchar               | nvarchar or EM<br>-881 | char                   | varchar or EM<br>-881  | char                   | char                   |
| <b>Other</b>         | nchar               | nvarchar or EM<br>-881 | char                   | varchar or EM<br>-881  | char                   | char                   |

The following are among the differences between the return values in this release and what Informix® versions earlier than 11.50.xC2 return:

- Earlier releases accept LVARCHAR arguments, but cannot return LVARCHAR values.
- If the result is longer than the maximum size of the argument of the longest data type, earlier releases do not support data-type promotion, but issue error -881. (This is typically with VARCHAR or NVARCHAR arguments, if the length of the resulting string would be greater than 255 bytes.)

For all versions of Informix®, error -881 is issued if the length of a returned string exceeds 32Kb.

## ASCII Function

The **ASCII** function returns the decimal representation of the first character in a character string, based on its codepoint in the ASCII character set.

ASCII Function

**ASCII**(*char\_expr*)

| Element          | Description  | Restrictions  | Syntax                                  |
|------------------|--|---|---|
| <i>char_expr</i> | Expression that evaluates to a character data type | Must be of type CHAR, LVARCHAR, NCHAR, NVARCHAR, or VARCHAR | <a href="#">Identifier on page 1456</a> |

The **ASCII** function takes a single argument of any character data type. It returns an integer value, based on the first character of the argument, corresponding to the decimal representation of the codepoint of that character within the ASCII character set.

If the argument is NULL, or if the argument is an empty string, the **ASCII** function returns a NULL value.

The following query returns the ASCII value of uppercase **H**:

```
SELECT ASCII("HELLO") FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

| (constant) |
|------------|
| 72         |

The following query returns the ASCII value of lowercase **h**:

```
SELECT ASCII("hello") FROM systables WHERE tabid = 1;
```

The following table shows the output of this SELECT statement.

| (constant) |
|------------|
| 104        |

The following query returns the **ASCII** output from an empty string argument:

```
SELECT ASCII('') FROM systables WHERE tabid = 1;
```

The following table shows the NULL output of this SELECT statement.

---

---

**(constant)**

---

---

The following query returns the **ASCII** output from a NULL argument:

```
SELECT ASCII(NULL) FROM systables WHERE tabid = 1;
```

The following table shows the NULL output of this SELECT statement.

---

---

**(constant)**

---

---

The **ASCII** function interprets this argument as a NULL expression, rather than as a value that begins with uppercase N.

For a table of the numeric values of the codepoints in the ASCII character set, see [Collating Order for U.S. English Data on page 1431](#).

## TRIM Function

The **TRIM** function removes specified leading or trailing pad characters from a string. (See also the descriptions of the **LTRIM** and **RTRIM** functions, which provide similar functionality, but support a different syntax.)

TRIM Function

**TRIM**

(

**BOTH**

**TRAILING LEADING**

*pad\_char*

**FROM**

*source\_expression*)

| Element                  | Description   | Restrictions                   | Syntax                                  |
|--------------------------|---|--------------------------------|---|
| <i>pad_char</i>          | Expression that evaluates to a single character or NULL. The default is a blank space (= ASCII 32). | Must be a character expression | <a href="#">Expression on page 1193</a> |
| <i>source_expression</i> | Character expression, including a character column name, or a call to another <b>TRIM</b> function  | Cannot be a DISTINCT data type | <a href="#">Expression on page 1193</a> |

The **TRIM** function returns a character string identical to its *source\_expression* argument, except that any leading or trailing pad characters, as specified by the LEADING, TRAILING, or BOTH keywords, are deleted. If no trim qualifier (LEADING, TRAILING, or BOTH) is specified, BOTH is the default. If no *pad\_char* is specified, a single blank space (the ASCII 32

character) is the default, and leading or trailing blank spaces, as specified by the qualifying keyword, are deleted from the returned value.

If either the *pad\_char* or the *source\_expression* evaluates to NULL, the result of the **TRIM** function is NULL.

The data type of the returned value depends on the *source\_expression* argument:

- If the argument is longer than 255 bytes, the returned value is of type LVARCHAR.
- If the argument has 255 bytes or fewer, the data type of the returned value depends on the data type of the argument:
  - If the argument is of type CHAR or VARCHAR, a VARCHAR value is returned.
  - If the argument is of type NCHAR or NVARCHAR, an NVARCHAR value is returned.
  - If the argument is of type LVARCHAR, an LVARCHAR value is returned.

The length of the returned value is 255 bytes or fewer for VARCHAR or NVARCHAR *source\_expression* arguments, and no more than 32,739 bytes for CHAR, NCHAR, or LVARCHAR arguments.

The following example shows some generic uses for the **TRIM** function:

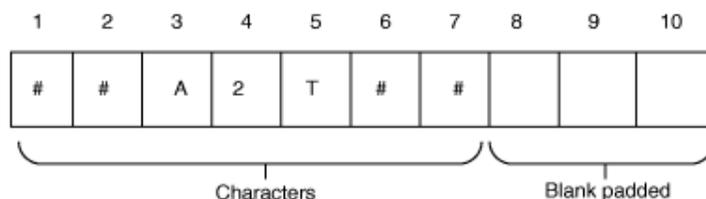

```
SELECT TRIM (c1) FROM tab;
SELECT TRIM (TRAILING '#' FROM c1) FROM tab;
SELECT TRIM (LEADING FROM c1) FROM tab;
UPDATE c1='xyz' FROM tab WHERE LENGTH(TRIM(c1))=5;
SELECT c1, TRIM(LEADING '#' FROM TRIM(TRAILING '%' FROM
'###abc%%')) FROM tab;
```

In Dynamic SQL, when you use the DESCRIBE statement with a SELECT statement that calls the **TRIM** function in the Projection list, the data type of the trimmed column that DESCRIBE returns depends on the data type of the *source\_expression*, for SQL data type constants defined in the **sqltypes.h** header file of the Informix® ESQL/C source file. For further information on the GLS aspects of the **TRIM** function in Informix® ESQL/C, see the *Informix® GLS User's Guide*.

## Fixed Character Columns

The **TRIM** function can be specified on fixed-length character columns. If the length of the string is not completely filled, the unused characters are padded with blank space. [Figure 13: Column Entry in a Fixed-Length Character Column on page 1335](#) shows this concept for the column entry '##A2T##', where the column is defined as CHAR(10).

Figure 13. Column Entry in a Fixed-Length Character Column

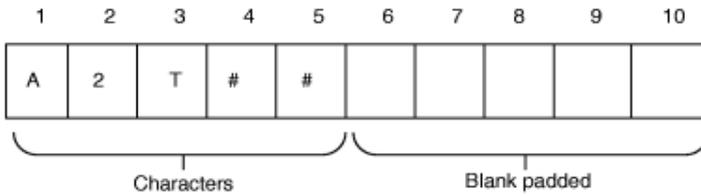

If you want to trim the sharp sign (#) *pad\_char* from the column, you need to consider the blank padded spaces as well as the actual characters.

For example, if you specify the keyword BOTH, the result from the trim operation is `A2T##`, because the **TRIM** function does not match the blank padded space that follows the string. In this case, the only sharp signs ( # ) trimmed are those that precede the other characters. The SELECT statement is shown, followed by [Figure 14: Result of TRIM Operation on page 1336](#), which presents the result.

```
SELECT TRIM(LEADING '#' FROM col1) FROM taba;
```

Figure 14. Result of TRIM Operation

This SELECT statement removes all occurrences of the sharp ( # ) sign:

```
SELECT TRIM(BOTH '#' FROM TRIM(TRAILING ' ' FROM col1)) FROM taba;
```

## LTRIM Function

The **LTRIM** function removes specified leading pad characters from a string.

LTRIM Function

```
LTRIM(source_string
,pad_string
)
```

| Element              | Description   | Restrictions  | Syntax                                  |
|----------------------|---|---|---|
| <i>pad_string</i>    | Expression that specifies one or more characters to delete from <i>source_string</i>                | Must be a character expression  | <a href="#">Expression on page 1193</a> |
| <i>source_string</i> | Expression that specifies a character string from which characters in <i>pad_string</i> are deleted | Pad characters to the right of any character not in <i>pad_string</i> are not deleted | <a href="#">Expression on page 1193</a> |

The first argument to the **LTRIM** function must be a character expression from which to delete leading pad characters. The optional second argument is a character expression that evaluates to a string of pad characters. If no second argument is provided, only blank characters are regarded as pad characters.

The return data type of the **LTRIM** function is based on its *source\_string* argument, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The value returned contains a substring of *source\_string*, but from which any leading pad characters to the left of the first non-pad character have been removed. If a host variable is used, an LVARCHAR data type is returned.

The **LTRIM** function scans a copy of the *source\_string* from the left, deleting any leading characters that appear in the *pad\_string*. If no *pad\_string* argument is specified, only leading blanks are deleted from the returned value. When the first non-pad character is encountered, the function returns its result string and terminates.

In the following example, the *pad\_string* is 'Hello':

```
SELECT LTRIM('Hellohello world!', 'Hello') FROM mytab;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

hello world!

---

Here the first five characters of the *source\_string* were dropped because they matched characters in the *pad\_string*, but the function terminated after it encountered the lowercase **h** character, which preserved the trailing 'ello' pad characters to its right.

## RTRIM Function

The **RTRIM** function removes specified trailing pad characters from a string.

RTRIM Function

```
RTRIM(source_string  
,pad_string  
)
```

| Element              | Description   | Restrictions   | Syntax                                  |
|----------------------|---|--|---|
| <i>pad_string</i>    | Expression that specifies one or more characters to delete from <i>source_string</i>                | Must be a character expression   | <a href="#">Expression on page 1193</a> |
| <i>source_string</i> | Expression that specifies a character string from which characters in <i>pad_string</i> are deleted | Pad characters to the left of any character not in <i>pad_string</i> are not deleted | <a href="#">Expression on page 1193</a> |

The first argument to the **RTRIM** function must be a character expression from which to delete trailing pad characters. The optional second argument is a character expression that evaluates to a string of pad characters. If no second argument is provided, only blank characters are regarded as pad characters.

The return data type of the **LTRIM** function is based on its *source\_string* argument, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The value returned contains a substring of *source\_string*, but from which any trailing pad characters to the right of the first non-pad character have been removed. If a host variable is used, an LVARCHAR data type is returned.

The **RTRIM** function scans a copy of the *source\_string* from the right, deleting any trailing characters that appear in the *pad\_string*. If no *pad\_string* argument is specified, only trailing blanks are deleted from the returned value. When the first non-pad character is encountered, the function returns its result string and terminates.

In the following example, the *pad\_string* is ' theend!\*#?':

```
SELECT RTRIM('good night... *!#?theend ', ' theend!*#?') AS closing FROM mytab;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

good night...

---

Here the last fifteen characters of the *source\_string* were dropped because they matched characters in the *pad\_string*, but the function terminated after it encountered the period (.) characters, which preserved the leading ' thn' pad characters to the left.

## SPACE function

The SPACE function creates a character string of a specified number of blank spaces. The maximum length of the returned string value can be 32,739 blank characters.

The function has this syntax:

SPACE Function

**SPACE**(*expression*)

| Element           | Description  | Restrictions   | Syntax                                  |
|-------------------|--|--|---|
| <i>expression</i> | Expression that evaluates to a non-negative whole number < 256 | Must be an expression, constant, column, or host variable of a built-in integer type, or one that can be converted to an integer | <a href="#">Expression on page 1193</a> |

The argument to the SPACE function must be of a built-in data type.

The SPACE function returns an LVARCHAR string of the specified number of blank (ASCII 32) characters.

If the argument evaluates to a NULL value, or to a number less than 1, this function returns a NULL value, rather than an empty string.

In the following example, the SPACE function returns a single-character blank string:

```
SELECT SPACE(1) FROM tabula_rasa;
```

The following table shows the output from this SELECT statement, which is a single blank character:

---

**(constant)**

---

## REVERSE function

The **REVERSE** function accepts a character expression as its argument, and returns a string of the same length, but with the ordinal positions of every logical character reversed.

This is the syntax of the **REVERSE** function:

REVERSE Function

**REVERSE**(*source\_string*)

| Element              | Description                                     | Restrictions  | Syntax                                  |
|----------------------|---|---|---|
| <i>source_string</i> | Expression that evaluates to a character string | Must be an expression, constant, column, or host variable of a type that can be converted to a character type | <a href="#">Expression on page 1193</a> |

The argument to the **REVERSE** function cannot have a user-defined data type. The built-in CHAR, LVARCHAR, NCHAR, NVARCHAR, and VARCHAR types are valid.

The **REVERSE** function returns a string of the same data type as its *source\_string* argument.

If the expression that you specify as the argument evaluates to NULL, the return value is NULL.

For an argument that evaluates to string of *N* characters, the ordinal position *p* of each character in the *source\_string* becomes  $(N + 1 - p)$  in the returned string. This inverts the sequence of characters from their original order in the *source\_string*, so that the return value begins with the last character of the *source\_string*, and ends with the first character of the *source\_string*.

For example, the function expression `REVERSE('Mood')` returns the string `dooM` from the quoted-string argument. In both single-byte and multibyte code sets, only the ordinal positions are reversed, not the characters themselves. In the function expression above, 'd' does not become 'b', and each logical character in a multibyte code set (for example, **utf8**, or **GB2312-80**) is repositioned as a single logical unit.

If the argument evaluates to a single-character or to an empty *source\_string*, the return value and the *source\_string* are identical, as if the **REVERSE** function had no effect. For strings that include multiple characters, this equality is true only when the *source\_string* is a palindrome. For character strings where  $\text{MOD}(N, 2) = 1$ , the character in ordinal position  $(N+1)/2$  has the same middle position in both the *source\_string* and in the returned string.

In the following example, the **REVERSE** function reverses a quoted string argument:

```
SELECT REVERSE('Able was I ere I saw Elba.') FROM Mirror_Table;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

```
.ablE was I ere I saw elbA
```

---

## REPLACE Function

The **REPLACE** function replaces specified characters within a source string with different characters.

REPLACE Function

```
REPLACE(source_string ,old_string
,new_string
)
```

| Element              | Description  | Restrictions  | Syntax                                  |
|----------------------|--|---|---|
| <i>new_string</i>    | Character or characters that replace <i>old_string</i> in the return string                  | Must be an expression, constant, column, or host variable of a data type that can be converted to a character data type | <a href="#">Expression on page 1193</a> |
| <i>old_string</i>    | Character or characters in <i>source_string</i> that are to be replaced by <i>new_string</i> | Must be an expression, constant, column, or host variable of a data type that can be converted to a character data type | <a href="#">Expression on page 1193</a> |
| <i>source_string</i> | String of characters argument to the <b>REPLACE</b> function                                 | Must be an expression, constant, column, or host variable of a data type that can be converted to a character data type | <a href="#">Expression on page 1193</a> |

Any argument to the **REPLACE** function must be of a built-in data type.

The **REPLACE** function returns a copy of *source\_string* in which every occurrence of *old\_string* is replaced by *new\_string*. If you omit the *new\_string* option, every occurrence of *old\_string* is omitted from the return string.

The return data type is its *source\_string* argument. If a host variable is the source, the return value is either NVARCHAR or NCHAR, according to the length of the returned string, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

In the following example, the **REPLACE** function replaces every occurrence of `xz` in the source string with `t`:

```
SELECT REPLACE('Mighxzy xzime', 'xz', 't')
FROM mytable;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

```
Mighty time
```

---

## LPAD Function

The **LPAD** function returns a copy of *source\_string* that is left-padded to the total number of characters specified by *length*.

LPAD Function

```
LPAD ( source_string , length
, pad_string
)
```

| Element              | Description  | Restrictions  | Syntax                                      |
|----------------------|--|---|---|
| <i>length</i>        | Integer value that specifies total number of characters in the returned string | Must be an expression, constant, column, or host variable of a data type that can be converted to an integer data type  | <a href="#">Literal Number on page 1419</a> |
| <i>pad_string</i>    | String that specifies the pad character or characters                          | Must be an expression, constant, column, or host variable of a data type that can be converted to a character data type | <a href="#">Expression on page 1193</a>     |
| <i>source_string</i> | String that serves as input to the LPAD function                               | Must be an expression, constant, column, or host variable of a data type that can be converted to a character data type | <a href="#">Expression on page 1193</a>     |

Any argument to the **LPAD** function must be of a built-in data type.

The *pad\_string* parameter specifies the character or characters to be used for padding the source string. The sequence of pad characters occurs as many times as necessary to make the return string the storage length specified by *length*.

The series of pad characters in *pad\_string* is truncated if it is too long to fit into *length*. If you specify no *pad\_string*, the default value is a single blank (ASCII 32) character.

The return data type is based on the three arguments, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

In the following example, the user specifies that the source string is to be left-padded to a total length of 16 characters. The user also specifies that the pad characters are a series consisting of a hyphen and an underscore (-\_).

```
SELECT LPAD('Here we are', 16, '-_') FROM mytable;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

```
_-_Here we are
```

---

## RPAD Function

The **RPAD** function returns a copy of *source\_string* that is right-padded to the total number of characters that the *length* argument specifies.

RPAD Function

```
RPAD ( source_string , length
, pad_string
)
```

| Element              | Description   | Restrictions  | Syntax                                      |
|----------------------|---|---|---|
| <i>length</i>        | The total number of characters in the returned string | Must be an expression, constant, column, or host variable that returns an integer                                       | <a href="#">Literal Number on page 1419</a> |
| <i>pad_string</i>    | String that specifies the pad character or characters | Must be an expression, column, constant, or host variable of a data type that can be converted to a character data type | <a href="#">Expression on page 1193</a>     |
| <i>source_string</i> | String that serves as input to the RPAD function      | Same as for <i>pad_string</i>   | <a href="#">Expression on page 1193</a>     |

Any argument to the **RPAD** function must be of a built-in data type.

The *pad\_string* parameter specifies the pad character or characters to be used to pad the source string.

The series of pad characters occurs as many times as necessary to make the return string reach the length that *length* specifies. The series of pad characters in *pad\_string* is truncated if it is too long to fit into *length*. If you omit the *pad\_string* parameter, the default value is a single blank space (the ASCII 32 character).

The return data type is based on the *source\_string* and *pad\_string* arguments, if both are specified. If a host variable is the source, the return value is either NVARCHAR or NCHAR, according to the length of the returned string, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The UNLOAD feature of DB-Access truncates trailing blanks in CHAR or NCHAR columns, even if the **RPAD** function has appended blank characters to the data value. You must explicitly cast the CHAR or NCHAR value to a VARCHAR, LVARCHAR, or NVARCHAR data type if you need UNLOAD to preserve trailing blank characters or nonprintable characters in a value that **RPAD** returns.

In the following example, the user specifies that the source string is to be right-padded to a total length of 18 characters. The user also specifies that the pad characters to be used are a sequence consisting of a question mark and an exclamation point (?!)

```
SELECT RPAD('Where are you', 18, '?!')
FROM mytable;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

Where are you?!?!?

---

## CHR Function

This function accepts an unsigned integer argument, and returns a single logical character.

The **CHR** function has this syntax:

CHR Function

**CHR**(*expression*)

| Element           | Description   | Restrictions  | Syntax                                  |
|-------------------|---|---|---|
| <i>expression</i> | Expression that evaluates to a nonnegative whole number less than 256 | Must be an integer in the range 0 through 255 (inclusive) | <a href="#">Expression on page 1193</a> |

The data type of the return value is VARCHAR(1).

The argument can be SMALLINT, INTEGER, SERIAL, INT8, SERIAL8, BIGINT, or BIGSERIAL. The argument must evaluate to a whole number in the range 0 through 255.

If the argument is an integer in the range 0 through 127, the return value is the corresponding single-byte ASCII code point. For a listing of the characters corresponding to the ASCII code points 0 through 127, see [Collating Order for U.S. English Data on page 1431](#).

If the argument is an integer in the range 128 through 255, the return value is the corresponding 2-byte code point in the default code set.

- On UNIX™ platforms, the default code set is ISO8859-1.
- On Windows™ platforms, the default code set is Microsoft™ 1252.

## Case-Conversion Functions

The case-conversion functions perform lettercase conversion on alphabetic characters. In the default locale, only the ASCII characters in the ranges A - z and a - z can be modified by these functions, which enable you to perform case-insensitive searches in your queries and to specify the format of the output.

The case-conversion functions are **UPPER**, **LOWER**, and **INITCAP**. The following diagram shows the syntax of these case-conversion functions.

## Case-Conversion Functions

**UPPER LOWER INITCAP***(expression)*

| Element           | Description                             | Restrictions   | Syntax                                  |
|-------------------|---|--|---|
| <i>expression</i> | Expression returning a character string | Must be a built-in character type. If a host variable, its length must be long enough to store the converted string. | <a href="#">Expression on page 1193</a> |

The *expression* must return a character data type. When a column expression is specified, the column data type returned by the database server is that of *expression*. For example, if the input type is CHAR, the output type is also CHAR.

Argument to these functions must be of the built-in data types.

In all locales, the byte length returned from the description of a column with a case-conversion function is the input byte length of the source string. If you use a case-conversion function with a multibyte *expression* argument, the conversion might increase or decrease the length of the string. If the byte length of the result string exceeds the byte length *expression*, the database server truncates the result string to fit into the byte length of *expression*.

Only characters designated as ALPHA class in the locale file are converted, and this occurs only if the locale recognizes the construct of lettercase.

If *expression* evaluates to NULL, the result of a case-conversion function is also NULL.

The database server treats a case-conversion function as an SPL routine in the following instances:

- If it has no argument
- If it has one argument, and that argument is a named argument
- If it has more than one argument
- If it appears in the Projection list with a host variable as an argument

If none of the conditions in the preceding list are met, the database server treats a case-conversion function as a system function.

The following example uses all the case-conversion functions in the same query to specify multiple output formats for the same value:

```
Input value:

SAN Jose

Query:

SELECT City, LOWER(City), LOWER("City"),
       UPPER (City), INITCAP(City)
   FROM Weather;

Query output:

SAN Jose  san jose  city  SAN JOSE  San Jose
```

## UPPER Function

The **UPPER** function accepts an *expression* argument and returns a character string in which every lowercase alphabetical character in the *expression* is replaced by a corresponding uppercase alphabetic character.

The following example uses the **UPPER** function to perform a case-insensitive search on the **lname** column for all employees with the last name of **Curran**:

```
SELECT title, INITCAP(fname), INITCAP(lname) FROM employees
WHERE UPPER (lname) = "CURRAN"
```

Because the **INITCAP** function is specified in the projection list, the database server returns the results in a mixed-case format. For example, the output of one matching row might read: `accountant James Curran.`

## LOWER Function

The **LOWER** function accepts an *expression* argument and returns a character string in which every uppercase alphabetic character in the *expression* is replaced by a corresponding lowercase alphabetic character.

The following example shows how to use the **LOWER** function to perform a case-insensitive search on the **City** column. This statement directs the database server to replace all instances (that is, any variation) of the words `san jose`, with the mixed-case format, `San Jose`.

```
UPDATE Weather SET City = "San Jose"
WHERE LOWER (City) = "san jose";
```

## INITCAP Function

The **INITCAP** function returns a copy of the *expression* in which every word in the *expression* begins with an uppercase letter. With this function, a *word* begins after any character other than a letter. Thus, in addition to a blank space, symbols such as commas, periods, colons, and so on, introduce a new word.

For an example of the **INITCAP** function, see [UPPER Function on page 1345](#).

## Case-conversion functions in NLSCASE INSENSITIVE databases

The **UPPER** and **LOWER**, case-conversion functions were designed to support case-insensitive queries in a case-sensitive database. They are less often needed in databases that have the NLSCASE INSENSITIVE attribute, because the NCHAR and NVARCHAR data types can support case-insensitive queries without calling these functions. You can invoke the case-conversion functions in NLSCASE INSENSITIVE databases, where their effects on CHAR, LVARCHAR, and VARCHAR data types are the same as in case-sensitive databases.

In a database created with the NLSCASE INSENSITIVE option, the database server disregards the lettercase of NCHAR and NVARCHAR values. Expressions that call case-conversion functions can return different results from what a case-sensitive database would return, if the expression references NCHAR or NVARCHAR objects, or if the database server evaluates the expression with an explicit or implicit cast to an NCHAR or NVARCHAR data type.

When the **UPPER**, **LOWER**, or **INITCAP** function is used in evaluating a string expression in a database with the NLSCASE INSENSITIVE property, the database server invokes the function, and applies to its return value the data-type promotion rules that are summarized in the topic [Return Types from CONCAT and String Functions on page 1328](#).

- If the expression evaluates to a CHAR, NVARCHAR, or VARCHAR data type, the database server can use that result in case-sensitive operations, if those operations do not involve NCHAR or NVARCHAR objects.
- If the expression evaluates to an NCHAR or NVARCHAR value after the **UPPER**, **LOWER**, or **INITCAP** function has executed, the case of letters in this result is disregarded in subsequent operations that use this return value from the expression.

The following example illustrates this behavior in an NLSCASE INSENSITIVE database, in which table **t1** has a character column of each of the five built-in character data types. The table stores three rows, in which each column stores the same lettercase variants of a 3-letter character string:

```
CREATE DATABASE db NLSCASE INSENSITIVE;
CREATE TABLE t1 (
  c1 NCHAR(20),
  c2 NVARCHAR(20),
  c3 CHAR(20),
  c4 VARCHAR(20),
  c5 LVARCHAR(20)) ;
INSERT INTO t1 values ('ibm', 'ibm', 'ibm', 'ibm', 'ibm');
INSERT INTO t1 values ('Ibm', 'Ibm', 'Ibm', 'Ibm', 'Ibm');
INSERT INTO t1 values ('IBM', 'IBM', 'IBM', 'IBM', 'IBM');
```

In the following example, the database server applies the **UPPER** function to the NCHAR column **c1** and then applies a case-insensitive rule to return all values in that column that match the `'IBM'` string constant.

```
SELECT c1 FROM t1 WHERE UPPER(c1) = 'IBM';
```

Because NCHAR values are not case sensitive in this database, the query returns the column **c1** value from every row in the table, because in each row the sequence of letters matches the string constant, using a case-insensitive rule that ignores the letter case of the column values:

```
c1
ibm
Ibm
IBM
```

The same result set (namely `'ibm'`, `'Ibm'`, and `'IBM'`) would be also returned by the following modifications to the same query on the same table:

- If the projection clause specified any other column, rather than **c1**, because every column stores the same values, and the NCHAR value that **UPPER** returns makes the WHERE clause true for all lettercase variants of the string `'IBM'` in this database.
- If the `'IBM'` string in the WHERE clause were any other lettercase variant of the same sequence of letters, because NCHAR data types are not processed by case-sensitive rules in this database.
- If the NVARCHAR column **c2**, rather than NCHAR column **c1**, were the argument to the case-conversion function, because both NCHAR or NVARCHAR are case-insensitive data types in this database.

- If the case-conversion function **LOWER** or **INITCAP**, rather than **UPPER**, were applied to column **c1**, because every (case-variant) value that NCHAR column matches `'IBM'` in this database.
- If no case-conversion function were called, but the WHERE condition instead specified `c1 = 'IBM'`, because case-conversion functions have no effect as query filters on NCHAR or NVARCHAR arguments in this NLSCASE INSENSITIVE database.

## Substring functions

The built-in SQL substring functions return substrings from character string arguments, or return positional information for operations on substrings.

Substring Functions

<sup>612</sup>CHARINDEX function <sup>613</sup>

<sup>612</sup>INSTR function <sup>617</sup>

LEFT function <sup>618</sup>

RIGHT function <sup>619</sup>

SUBSTR function <sup>615</sup>

SUBSTRB function <sup>616</sup>

SUBSTRING function <sup>614</sup>

SUBSTRING\_INDEX function <sup>620</sup>

Sections that follow describe the syntax and usage of these substring functions.

## CHARINDEX function

The **CHARINDEX** function searches a character string for the first occurrence of a target substring, where the search begins at a specified or default character position within the source string.

The **CHARINDEX** function has this syntax:

612. Informix® extension

613. See [CHARINDEX function on page 1347](#)

614. See [SUBSTRING function on page 1355](#)

615. See [SUBSTR function on page 1352](#)

616. See [SUBSTRB function on page 1354](#)

617. See [INSTR function on page 1349](#)

618. See [LEFT function on page 1351](#)

619. See [RIGHT function on page 1351](#)

620. See [SUBSTRING\\_INDEX function on page 1357](#)

## CHARINDEX function

```
CHARINDEX(substring, source
,start_position
)
```

| Element               | Description  | Restrictions  | Syntax                                  |
|-----------------------|--|---|---|
| <i>source_string</i>  | Expression that evaluates to a character string  | Must be an expression, constant, column, or host variable of a built-in character type, or a type that can be converted to a character type | <a href="#">Expression on page 1193</a> |
| <i>start_position</i> | Ordinal position to begin the search in <i>source</i> , where 1 is the first logical character | Must be an expression, constant, column, or host variable of a built-in integer type, or that can be converted to an integer                | <a href="#">Expression on page 1193</a> |
| <i>substring</i>      | Expression that evaluates to a character string  | Must be an expression, constant, column, or host variable of a built-in character data type, or that can be converted to a character type   | <a href="#">Expression on page 1193</a> |

Arguments to **CHARINDEX** cannot be user-defined data types.

If either *source* or the *substring* is NULL, this function returns NULL.

If the optional *start\_position* value is less than 1, or if you omit this argument, none, the search for *substring* begins at the first logical character in the *source*, as if you had specified 1 as the starting position.

If no expression matching the *substring* is found, **CHARINDEX** returns zero ( 0 ). Otherwise it returns the ordinal position of the first logical character in the first occurrence of *substring*.

If you specify a *start\_position* greater than 1, any *substring* that begins before *start\_position* is ignored, and the function returns one of the following values:

- either the position of the first logical character in the first matching substring whose ordinal position is equal to or greater than *start\_position*,
- or else zero ( 0 ), if no occurrence of *substring* in *source* begins at or follows *start\_position*, or if *start\_position* is greater than the number of logical characters in *source*.

In locales that support multibyte character sets, the return value is the ordinal value among logical characters in the *source*. In single-byte locales, such as the default locale, the return value is equivalent to the byte position, where the first byte is in position 1.

In databases created with the NLSCASE INSENSITIVE option, if either *source* or *substring* is an NCHAR or NVARCHAR data type, the database server ignores variants in letter case in determining whether a given substring of *source* matches the target *substring*.

The following function expression returns 9:

```
CHARINDEX('com', 'www.ibm.com')
```

In the example above, **CHARINDEX** begins its search at the default starting position of 1.

The following function expression returns 2:

```
CHARINDEX('w', 'www.ibm.com', 2)
```

In the example above, because the last argument begins the search at position 2, **CHARINDEX** ignores two other matching substrings:

- 'w' in position 1, because the search begins at 2,
- and 'w' in position 3, because the function returns the position of only the first occurrence of a matching substring.

## INSTR function

The **INSTR** function searches a character string for a specified substring, and returns the character position in that string where an occurrence of that a substring ends, based on a count of substring occurrences.

The **INSTR** function has this syntax:

INSTR function

```
INSTR(source_string, substring
, start
, count
)
```

| Element              | Description   | Restrictions   | Syntax                                  |
|----------------------|---|--|---|
| <i>count</i>         | Expression that evaluates to an integer > 0   | Must be an expression, constant, column, or host variable of a built-in integer type, or that can be converted to an integer.                    | <a href="#">Expression on page 1193</a> |
| <i>source_string</i> | Expression that evaluates to a character string   | Must be an expression, constant, column, or host variable of a built-in character data type, or that can be converted to a character type        | <a href="#">Expression on page 1193</a> |
| <i>start</i>         | Ordinal position to begin the search in <i>source_string</i> , where 1 is the first logical character | Must be an expression, constant, column, or host variable of a built-in integer type, or that can be converted to a positive or negative integer | <a href="#">Expression on page 1193</a> |
| <i>substring</i>     | Expression that evaluates to a character string   | Must be an expression, constant, column, or host variable of a built-in character data type, or that can be converted to a character type        | <a href="#">Expression on page 1193</a> |

Arguments to **INSTR** cannot be user-defined data types.

The function returns NULL in each of these cases:

- *count* is less than or equal to zero (0).
- *source\_string* is NULL or of zero length.
- *substring* is NULL or of zero length.

The return value is zero (0) in each of the following cases:

- if no occurrences of *substring* are found in *source\_string*,
- if *start* is greater than the length of *source\_string*.
- If fewer than *count* occurrences of *substring* are in the *source\_string*,

If you omit the optional *count* argument, the default *count* value is 1.

In locales that support multibyte character sets, the return value is the ordinal value among logical characters in the *source\_string*. In single-byte locales, such as the default locale, the return value is equivalent to the byte position, where the first byte is in position 1.

### The start position

If *start* is omitted or is specified as zero, the search for *substring* begins at character position 1. If *start* is negative, the search for occurrences of *substring* begins at the end of *source\_string*, and proceeds towards the beginning.

- In a left-to-right locale, a negative *start* value specifies a right-to-left search.
- In a right-to-left locale, a negative *start* value specifies a left-to-right search.

In both types of locales, however, the search begins at the logical character position within *source\_string* that corresponds to the absolute value of *start*.

In a right-to-left locale, a negative *start* value specifies a left-to-right search.

### Examples of INSTR function expressions

The following expressions are all based on the same *source\_string* and *substring*. This example returns 3, as the character position of the first 'er' substring:

```
INSTR("wwerw.ibm.cerom", "er")
```

In the example above, both *start* and *count* default to 1.

The next example starts the search at the 2nd character position, with a default *count* of 1:

```
INSTR("wwerw.ibm.cerom", "er", 2)
```

The expression above returns 3, the position of the first character in the first 'er' substring that a left-to-right search encounters.

The next example specifies a count of 2, starting the search in the first character of the *source\_string*:

```
INSTR("wwerw.ibm.cerom", "er", 1, 2)
```

The expression above returns 12, the character position where the second 'er' begins.

The following example specifies -5 as the starting position, and the *count* specifies the first occurrence of "er" between the 5th position and the beginning of the *source\_string*:

```
INSTR("wwerw.ibm.cerom", "er", -5, 1)
```

This returns 3, corresponding to the occurrence of the "er" substring that begins in that position. The negative *start* argument specifies a right-to-left search, but the return value is 3, because the reading direction of strings and substrings in the default locale is left-to-right.

## LEFT function

The **LEFT** function returns a substring consisting of the leftmost *N* characters from a string argument.

The function has this syntax:

LEFT function

**LEFT**(*source\_string*, *position*)

| Element              | Description   | Restrictions   | Syntax                                  |
|----------------------|---|--|---|
| <i>position</i>      | Ordinal position (from the left) in the string; this character and all to the left are to be returned | Must be an expression, constant, column, or host variable of a built-in integer type, or that can be converted to an integer | <a href="#">Expression on page 1193</a> |
| <i>source_string</i> | Expression that evaluates to a character string   | Must be an expression, constant, column, or host variable of a data type that can be converted to a character type           | <a href="#">Expression on page 1193</a> |

The arguments to the **LEFT** function cannot be user-defined data types.

What the **LEFT** function returns depends on the number of logical characters in *source\_string* and on the value of *position*:

- If *source\_string* evaluates to a string with more than *position* characters, the return value is a substring of *source\_string*, consisting of all characters to the left of the specified *position*.
- If *source\_string* evaluates to a string with no more than *position* characters, the return value is the entire *source\_string*.
- If *source\_string* evaluates to NULL, or if *position* is zero or negative, then NULL is returned.
- If no *position* argument is specified, no string value is returned, and an exception is issued.

The return data type is the same as its *source\_string* argument. If a host variable is the source, the return value is either NVARCHAR or NCHAR, according to the length of the returned string, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The following function expression requests the first five characters of a quoted string:

```
LEFT('www.ibm.com',5)
```

In this example, the **LEFT** function returns the substring `www.i`

## RIGHT function

The **RIGHT** function returns a substring consisting of the rightmost *N* characters from a string argument.

The function has this syntax:

RIGHT function

**RIGHT**(*source\_string*, *position*)

| Element              | Description   | Restrictions   | Syntax                                  |
|----------------------|---|--|---|
| <i>position</i>      | Ordinal position (from the right) in the string; this character and all to the right are to be returned | Must be an expression, constant, column, or host variable of a built-in integer type, or that can be converted to an integer | <a href="#">Expression on page 1193</a> |
| <i>source_string</i> | Expression that evaluates to a character string   | Must be an expression, constant, column, or host variable of a data type that can be converted to a character type           | <a href="#">Expression on page 1193</a> |

The arguments to the **RIGHT** function cannot be user-defined data types.

In left-to-right locales, such as the default U.S. English locale, this function returns a substring of trailing characters from the *source\_string*.

What the **RIGHT** function returns depends on the number of logical characters in *source\_string* and on the value of *position*:

- If *source\_string* evaluates to a string with more than *position* characters, the return value is a substring of *source\_string*, consisting of all characters to the right of the specified *position*.
- If *source\_string* evaluates to a string with no more than *position* characters, the return value is the entire *source\_string*.
- If *source\_string* evaluates to NULL, or if *position* is zero or negative, then NULL is returned.
- If no *position* argument is specified, no string value is returned, and an exception is issued.

The return data type is the same as its *source\_string* argument. If a host variable is the source, the return value is either NVARCHAR or NCHAR, according to the length of the returned string, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The following function expression requests the last five characters of a quoted string:

```
RIGHT('www.ibm.com',5)
```

In this example, the **RIGHT** function returns the substring `m.com`

## SUBSTR function

The **SUBSTR** function has the same purpose as the **SUBSTRING** function (to return a subset of a source string), but it uses different syntax.

## SUBSTR Function

```
SUBSTR(source_string ,start_position
,length
)
```

| Element               | Description  | Restrictions  | Syntax                                      |
|-----------------------|--|---|---|
| <i>length</i>         | Number of characters to be returned from <i>source_string</i>  | Must be an expression, literal, column, or host variable that returns an integer  | <a href="#">Expression on page 1193</a>     |
| <i>source_string</i>  | String that serves as input to the <b>SUBSTR</b> function  | Must be an expression, literal, column, or host variable of a data type that can be converted to a character data type        | <a href="#">Expression on page 1193</a>     |
| <i>start_position</i> | Column position in <i>source_string</i> where the <b>SUBSTR</b> function starts to return characters | Must be an integer expression, literal, column, or host variable. Can have a plus sign ( + ), a minus sign ( - ), or no sign. | <a href="#">Literal Number on page 1419</a> |

Any argument to the **SUBSTR** function must be of a built-in data type.

The **SUBSTR** function returns a subset of *source\_string*. The subset begins at the column position that *start\_position* specifies. The following table shows how the database server determines the starting position of the returned subset based on the input value of the *start\_position*.

| Value of Start_Position | How the Database Server Determines the Starting Position of the Returned Subset   |
|-------------------------|---|
| Positive                | Counts forward from the first character in <i>source_string</i>   |
| Zero (0)                | Counts forward from the first character in <i>source_string</i> (that is, treats a <i>start_position</i> of 0 as equivalent to 1)                                       |
| Negative                | Counts backward from an origin that immediately follows the last character in <i>source_string</i> . A value of -1 returns the last character in <i>source_string</i> . |

The *length* parameter specifies the number of logical characters (not the number of bytes) in the subset. If you omit the *length* parameter, the **SUBSTR** function returns the entire portion of *source\_string* that begins at *start\_position*.

If you specify a negative *start\_position* whose absolute value is greater than the number of characters in *source\_string*, or if *length* is greater than the number of characters from *start\_position* to the end of *source\_string*, **SUBSTR** returns NULL. (In this case, the behavior of **SUBSTR** is different from that of the **SUBSTRING** function, which returns all the characters from *start\_position* to the last character of *source\_string*, rather than returning NULL.)

The return data type is that of the *source\_string* argument. If a host variable is the source, the return value is either NVARCHAR or NCHAR, according to the length of the returned string, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The following example specifies that the string of characters to be returned begins at a starting position 3 characters before the end of a 7-character *source\_string*. This implies that the starting position is the fifth character of *source\_string*. Because

the user does not specify a value for *length*, the database server returns a string that includes all characters from character-position 5 to the end of *source\_string*.

```
SELECT SUBSTR('ABCDEFG', -3)
FROM mytable;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

EFG

---

## SUBSTRB function

Returns a substring of a string, beginning at a specified position in the string.

SUBSTRB Function

**SUBSTRB**(*source\_string*, *starting\_position*, *length*)

| Element              | Description  |
|----------------------|--|
| <i>length</i>        | <p>An expression that specifies the length of the result in bytes. If specified, the expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated.</p> <p>If the value of <i>length</i> is greater than the number of bytes from the starting position to the end of the string, the length of the result is equal to is the length of the first argument minus the starting position, plus one.</p> <p>If the value of <i>length</i> is less than or equal to zero, the result of SUBSTRB is a NULL string.</p> <p>The default for <i>length</i> is the number of bytes from the position specified by <i>starting_position</i> to the last byte of the string.</p> <p>When <i>length</i> is specified, the length of the result string is truncated to the value of <i>length</i>. In the following example, where <i>my_string</i> is a 10-byte string, the result string is limited to 5 bytes:</p> <pre>substrB(my_string, 3, 5)</pre> <p>If, in the preceding example, <i>my_string</i> is a 4-byte string and the starting position is the third byte, a 2-byte string is returned.</p> <p>If <i>length</i> is not specified, the length of the result is the length of <i>source_string</i> beginning from the <i>starting_position</i>. In the following example, where <i>my_string</i> is a 10-byte string, an 8-byte string is returned:</p> <pre>substrB(my_string, 3)</pre> |
| <i>source_string</i> | <p>An expression that specifies the string from which the result is derived. The expression must return a value that is a built-in string, numeric, or datetime data type. If the value is not a string data type, it</p>  |

| Element                  | Description   |
|--------------------------|---|
|                          | is implicitly cast to NVARCHAR before the function is evaluated. A NULL value is returned for a zero length result.   |
| <i>starting_position</i> | <p>An expression that specifies the starting position in string of the beginning of the result substring. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. If the value is not of type INTEGER, it is implicitly cast to an INTEGER before the function is evaluated.</p> <p>If <i>starting_position</i> is positive, then the starting position is calculated from the beginning of the string. If <i>starting_position</i> is greater than the <i>length</i> of string, then a null string is returned. If <i>starting_position</i> is negative, then the starting position is calculated from the end of the string and by counting backwards the number of bytes. If the absolute value of <i>starting_position</i> is greater than the <i>length</i> of <i>source_string</i>, then a null string is returned. If <i>starting_position</i> is 0, then a starting position of 1 is used.</p> <p> <b>Note:</b> All units of <i>length</i> and <i>starting_position</i> are expressed in terms of bytes, even for strings encoded in multibyte code sets. SUBSTR uses the logical character size for multibyte strings. For example, if <i>starting_position</i> is 2 in the legacy SUBSTR and the first character of a multibyte string requires 3 bytes of storage, the 2 represents the fourth byte in the string. In SUBSTRB, the 2 represents the second byte in the string.</p> |

If *source\_string* is a CHAR or VARCHAR data type, the result of the function is a VARCHAR data type. Informix® does not support multiple code pages; instead, Informix® JDBC or ODBC translates the code page to the database.

If any argument is null, the result is the null value.

In dynamic SQL, *source\_string*, *starting\_position*, and *length* can be represented by a host variable. If a host variable is used for *source\_string*, the data type of the operand is VARCHAR, and the operand can be nullable.

Though not explicitly stated in the result definitions above, the semantics imply that if *source\_string* is a multi-byte character string, the result might contain fragments of multi-byte characters, depending on the values of *starting\_position* and *length*. For example, the result could possibly begin with the second byte of a multi-byte character, or end with the first byte of a multi-byte character. The SUBSTRB function detects these partial characters and replaces each byte of an incomplete character with a single blank character. SUBSTRB returns a fixed number of bytes; with SUBSTR, the number of returned varies according to the multibyte string.

## SUBSTRING function

The **SUBSTRING** function returns a subset of a character string.

SUBSTRING Function

```
SUBSTRING(source_string FROM start_position
FOR length
)
```

| Element               | Description  | Restrictions  | Syntax                                      |
|-----------------------|--|---|---|
| <i>length</i>         | Number of characters to return from <i>source_string</i>     | Must be an expression, constant, column, or host variable that returns an integer                               | <a href="#">Literal Number on page 1419</a> |
| <i>source_string</i>  | String argument to the <b>SUBSTRING</b> function             | Must be an expression, constant, column, or host variable whose value can be converted to a character data type | <a href="#">Expression on page 1193</a>     |
| <i>start_position</i> | Position in <i>source_string</i> of first returned character | Must be an expression, constant, column, or host variable that returns an integer                               | <a href="#">Literal Number on page 1419</a> |

Any argument to the **SUBSTRING** function must be of a built-in data type.

The return data type is that of the *source\_string* argument. If a host variable is the source, the return value is either NVARCHAR or NCHAR, according to the length of the returned string, using the return type promotion rules that the section [Return Types from the CONCAT Function on page 1328](#) describes.

The subset begins at the column position that *start\_position* specifies. The following table shows how the database server determines the starting position of the returned subset based on the input value of the *start\_position*.

| Value of Start_Position | How the Database Server Determines the Starting Position of the Return Subset   |
|-------------------------|---|
| Positive                | Counts forward from the first character in <i>source_string</i><br><br>For example, if <i>start_position</i> = 1, the first character in the <i>source_string</i> is the first character in the returned subset.  |
| Zero (0)                | Counts from one position before (that is, to the left of) the first character in <i>source_string</i><br><br>For example, if <i>start_position</i> = 0 and <i>length</i> = 1, the database server returns NULL, whereas if <i>length</i> = 2, the database server returns the first character in <i>source_string</i> . |
| Negative                | Counts backward from one position after (that is, to the right of) the last character in <i>source_string</i><br><br>For example, if <i>start_position</i> = -1, the starting position of the returned subset is the last character in <i>source_string</i> .   |

The size of the subset is specified by *length*. The *length* parameter refers to the number of logical characters, rather than to the number of bytes. If you omit the *length* parameter, or if you specify a *length* that is greater than the number of characters from *start\_position* to the end of *source\_string*, the **SUBSTRING** function returns the entire portion of *source\_string* that begins at *start\_position*. The following example specifies that the subset of the source string that begins in column position 3 and is two characters long should be returned:

```
SELECT SUBSTRING('ABCDEFG' FROM 3 FOR 2) FROM mytable;
```

The following table shows the output of this SELECT statement.

---

**(constant)**

---

CD

---

In the following example, the user specifies a negative *start\_position* for the return subset:

```
SELECT SUBSTRING('ABCDEFG' FROM -3 FOR 7)
FROM mytable;
```

The database server starts at the `-3` position (four positions before the first character) and counts forward for `7` characters. The following table shows the output of this SELECT statement.

---

**(constant)**

---

ABC

---

## SUBSTRING\_INDEX function

The **SUBSTRING\_INDEX** function searches a character string for a specified delimiter character, and returns a substring of the leading or trailing characters, based on a count of a delimiter that you specify as an argument to the function.

The **SUBSTRING\_INDEX** function has this syntax:

SUBSTRING\_INDEX function

**SUBSTRING\_INDEX**(*source\_string*,*delimiter*,*count*)

| Element              | Description   | Restrictions  | Syntax                                  |
|----------------------|---|---|---|
| <i>source_string</i> | Expression that evaluates to a character string             | Must be an expression, constant, column, or host variable of a built-in character data type, or that can be converted to a character type | <a href="#">Expression on page 1193</a> |
| <i>count</i>         | Expression that evaluates to a positive or negative integer | Must be an expression, constant, column, or host variable of a built-in integer type, or that can be converted to an integer.             | <a href="#">Expression on page 1193</a> |
| <i>delimiter</i>     | Expression that evaluates to a character string             | Must be an expression, constant, column, or host variable of a built-in character data type, or that can be converted to a character type | <a href="#">Expression on page 1193</a> |

Arguments to **SUBSTRING\_INDEX** cannot be user-defined data types.

This function returns NULL in each of the following cases:

- *source\_string* is NULL
- *delimiter* is NULL
- *count* = zero (0).

If the search finds fewer than *count* delimiters in the *source\_string*, the return value is the entire *source\_string*.

The return value has the same data type as the *source\_string*.

For *source\_string*, the sign of *count* determines whether the returned value is a substring of the leading characters or of the trailing characters in *source\_string*:

- The last character in the returned substring immediately precedes the Nth occurrence of that delimiter in a substring of leading characters, for  $N = \textit{count}$ .

For example, the function expression

```
SUBSTRING_INDEX("www.ibm.com", ".", 2)
```

returns the leading characters `www.ibm` because *count* > 0.

- The first character in the returned substring immediately precedes the Nth occurrence of that delimiter in a substring of trailing characters, for  $N = \textit{count} < 0$ .

For example, the function expression

```
SUBSTRING_INDEX("www.ibm.com", ".", -2)
```

returns the trailing characters `ibm.com` because *count* < 0.

The examples above apply to left-to-right locales, such as the default U.S. English locale, in which a negative value of *count* causes this function to return a substring of trailing characters from the *source\_string*, and a positive value of *count* causes this function to return a substring of leading characters from the *source\_string*,

In locales that support multibyte character sets, the return value is the ordinal value among logical characters in the *source\_string*. In single-byte locales, such as the default locale, the return value is equivalent to the byte position, where the first byte is in position 1.

## FORMAT\_UNITS Function

The **FORMAT\_UNITS** function can interpret strings that specify a number and the abbreviated names of units of memory or of mass storage.

This built-in function can accept one, two, or three quoted string arguments. You can invoke **FORMAT\_UNITS** in SQL statements that process size specifications expressed by standard abbreviations for bytes or for larger units (such as kilobytes, megabytes, gigabytes, and so forth) of memory or of mass storage.

The **FORMAT\_UNITS** function can also be called internally in the **sysadmin** database by the SQL administration API **ADMIN** and **TASK** functions, which are described in the *Informix® Administrator's Reference*.

FORMAT\_UNITS Function

**FORMAT\_UNITS**(

*'numberunits'*

*'number'*

*number*

*,'units'*

,

*'precision'*

*precision*

)

| Element          | Description   | Restrictions  | Syntax                                     |
|------------------|---|---|--|
| <i>number</i>    | Expression that evaluates to the number of storage or memory <i>units</i>   | Must be a literal number or a quoted string specifying a number that can be converted to FLOAT  | <a href="#">Expression on page 1193</a>    |
| <i>precision</i> | Integer number of significant digits to return from <i>number</i>           | Must be a literal number or a quoted string specifying an integer   | <a href="#">Expression on page 1193</a>    |
| <i>units</i>     | Abbreviation of a unit of storage or memory; the default is 'B' (for bytes) | Must begin with 'B', 'K', 'M', 'G', 'T', 'P', or 'PB' (or the lowercase forms of these letters). Any trailing characters are ignored. | <a href="#">Quoted String on page 1424</a> |

This built-in function can accept one, two, or three arguments. The returned value is a character string that shows the specified *number* and an appropriate format label that shows the storage units. If you specify a *precision* as the last argument, the *number* is returned with that precision. Otherwise, the *number* is formatted to precision 3 (`%3.31f`) by default.

The same notation also applies to arguments to all SQL administration API **ADMIN** and **TASK** commands (except for commands that emulate the Enterprise Replication **cdr** utility) that specify sizes of memory, of disk storage, or of address offsets:

#### Notation

##### Corresponding Units

##### 'B' or 'b'

Bytes (= 2 to the power 0)

##### 'K' or 'k'

Kilobytes (= 2 to the power 10)

##### 'M' or 'm'

Megabytes (= 2 to the power 20)

##### 'G' or 'g'

Gigabytes (= 2 to the power 30)

**'T' or 't'**

Terabytes (= 2 to the power 40)

**'PB'**

Petabytes (= 2 to the power 50)

**'P'**

Pages (= 2 kilobytes or 4 kilobytes, depending on the base page size of the system)

The initial letter in the *unit* specification ('B', 'K', 'M', 'G' or 'T') determines the units of measure, and any trailing characters are ignored. An exception, however, is if the initial letter 'P' (or 'p') is immediately followed by 'B' or 'b' in the string, because in this case the string is interpreted as petabytes. Any other string starting with "P" (such as "PA", "pC", "PhD", "papyrus" and so forth) is interpreted as specifying *pages*, rather than *petabytes*.

If one argument provides both the *number* and *units* specifications, Informix® ignores any whitespace that separates the *number* specification from the *units* specification within the same argument to the **FORMAT\_UNITS**, or SQL administration API **ADMIN** or **TASK** functions. For example, the specifications '128M' and '128 m' are both interpreted as 128 megabytes.

The following examples invoke the **FORMAT\_UNITS** function with a single argument:

```
EXECUTE FUNCTION FORMAT_UNITS('1024 M');
```

The following character string value is returned.

---

**(expression)**

---

1.00 GB

---

```
SELECT FORMAT_UNITS('1024 k') FROM systables WHERE tabid=1;
```

The following character string value is returned.

---

**(expression)**

---

1.00 MB

---

```
SELECT FORMAT_UNITS(tabid || 'M') FROM systables WHERE tabid=100;
```

The following character string value is returned.

---

**(expression)**

---

100 MB

---

The following examples show calls to the **FORMAT\_UNITS** function with two arguments:

```
EXECUTE FUNCTION FORMAT_UNITS(1024, 'k');
```

The following character string value is returned.

---

**(expression)**

---

1.00 MB

---

```
SELECT FORMAT_UNITS( SUM(chksize), 'P') SIZE,
       FORMAT_UNITS( SUM(nfree), 'p') FREE FROM syschunks;
```

```
size 117 MB
free 8.05 MB
```

This query returns the string values `size 117 MB` and `free 8.05 MB`.

The following examples show calls to the **FORMAT\_UNITS** function with three arguments:

```
EXECUTE FUNCTION FORMAT_UNITS(1024, 'k', 4);
```

The following character string value is returned.

---

**(expression)**

---

1.000 MB

---

```
SELECT FORMAT_UNITS( SUM(chksize), 'P', 4), SIZE,
       FORMAT_UNITS( SUM(nfree), 'p', 4) FREE FROM syschunks;
```

```
size 117.2 MB
free 8.049 MB
```

This query returns the string values `size 117.2 MB` and `free 8.047 MB`. These results differ from the previous example of a query only in their non-default precision, which the last argument to **FORMAT\_UNITS** specifies.

## IFX\_ALLOW\_NEWLINE Function

The **IFX\_ALLOW\_NEWLINE** function sets a newline mode that allows newline characters in quoted strings or disallows newline characters in quoted strings within the current session.

The **IFX\_ALLOW\_NEWLINE** function has the following syntax.

IFX\_ALLOW\_NEWLINE Function

**IFX\_ALLOW\_NEWLINE**

```
(
't' 'f'
)
```

If you enter `'t'` as the argument of this function, you enable newline characters in quoted strings in the session. If you enter `'f'` as the argument, you disallow newline characters in quoted strings in the session.

You can set the newline mode for all sessions by setting the `ALLOW_NEWLINE` parameter in the `ONCONFIG` file to a value of `0` (newline characters not allowed) or to a value of `1` (newline characters allowed). If you do not set this configuration

parameter, the default value is 0. Each time you start a session, the new session inherits the newline mode set in the `ONCONFIG` file. To change the newline mode for the session, execute the `IFX_ALLOW_NEWLINE` function. Once you have set the newline mode for a session, the mode remains in effect until the end of the session or until you execute the `IFX_ALLOW_NEWLINE` function again within the session.

In the following example, assume that you did not specify any value for the `ALLOW_NEWLINE` parameter in the `ONCONFIG` file, so, by default, newline characters are not allowed in quoted strings in any session. After you start a new session, you can enable newline characters in quoted strings in that session by executing the `IFX_ALLOW_NEWLINE` function:

```
EXECUTE PROCEDURE IFX_ALLOW_NEWLINE('t');
```

In ESQL/C, the newline mode that is set by the `ALLOW_NEWLINE` parameter in the `ONCONFIG` file or by the execution of the `IFX_ALLOW_NEWLINE` function in a session applies only to quoted-string literals in SQL statements. The newline mode does not apply to quoted strings contained in host variables in SQL statements. Host variables can contain newline characters within string data regardless of the newline mode currently in effect.

For example, you can use a host variable to insert data that contains newline characters into a column even if the `ALLOW_NEWLINE` parameter in the `ONCONFIG` file is set to 0.

For further information on how the `IFX_ALLOW_NEWLINE` function affects quoted strings, see [Quoted String on page 1424](#). For further information on the `ALLOW_NEWLINE` parameter in the `ONCONFIG` file, see the .

## User-Defined Functions

A user-defined function (UDF) is a routine that you write in SPL or in a language external to the database, such as C or Java™, and that returns a value to its calling context.

A UDF as an expression has the following syntax:

User-Defined Functions

```
function(
,
parameter =
Expression621
,
Statement-Local Variable Declaration622
)
```

| Element         | Description          | Restrictions        | Syntax  |
|-----------------|----------------------|---------------------|---|
| <i>function</i> | Name of the function | Function must exist | <a href="#">Database Object Name on page 1450</a> |

621. See [Expression on page 1193](#)

622. See [Statement-Local Variable Declaration on page 1364](#)

| Element          | Description  | Restrictions  | Syntax                                  |
|------------------|--|---|---|
| <i>parameter</i> | Name of an argument that was declared in a CREATE FUNCTION statement | If you use the <i>parameter</i> = option for any argument in the called function, you must use it for all arguments | <a href="#">Identifier on page 1456</a> |

You can call user-defined functions within SQL statements. Unlike built-in functions, user-defined functions can be invoked only by the creator of the function, and by the DBA, and by users who have been granted the Execute privilege on the function. For more information, see [Routine-Level Privileges on page 603](#).

The following examples show some user-defined function expressions. The first example omits the *parameter* option when it lists the function argument:

```
read_address('Miller')
```

This second example uses the *parameter* option to specify the argument value:

```
read_address(lastname = 'Miller')
```

When you use the *parameter* option, the *parameter* name must match the name of the corresponding parameter in the function registration. For example, the preceding example assumes that the **read\_address()** function was registered as follows:

```
CREATE FUNCTION read_address(lastname CHAR(20))
RETURNING address_t ... ;
```

A *statement-local variable* (SLV) enables an application to transmit a value from a user-defined function call to another part of the same SQL statement.

#### To use an SLV with a call to a user-defined function

1. Write one or more OUT parameters (and for UDRs written in the Java™ or in the SPL language, INOUT parameters) for the user-defined function.

For information about how to write a UDR with OUT or INOUT parameters, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

2. When you register the user-defined function, specify the `OUT` keyword before each OUT parameter, and the `INOUT` keyword before each INOUT parameter.

For more information, see [Specifying INOUT Parameters for a User-Defined Routine on page 1517](#), and [Specifying OUT Parameters for User-Defined Routines on page 1516](#).

3. Declare the SLV in a function expression that calls the user-defined function with each OUT and INOUT parameter.

The call to the user-defined function must be made within a WHERE clause. For information about the syntax to declare the SLV, see [Statement-Local Variable Declaration on page 1364](#).

4. Use the SLV that the user-defined function has initialized within the SQL statement.

After the call to the user-defined function has initialized the SLV, you can use this value in other parts of the same SQL statement in which the SLV was declared, including subqueries of the query whose WHERE clause includes the SLV declaration. For information about the use of an SLV within the SELECT statement, see [Statement-Local Variable Expressions on page 1365](#).

Besides using a SLV to retrieve a value from an OUT or INOUT parameter, you can also use a local variable or a parameter of an SPL routine to retrieve values from an SPL or C routine that has OUT or INOUT parameters.

## Statement-Local Variable Declaration

The Statement-Local Variable Declaration declares a statement-local variable (SLV) in a call to a user-defined function that defines one or more OUT or INOUT parameters.

A Statement-Local Variable Declaration has this syntax:

Statement-Local Variable Declaration

*slv\_name* #

Built-In Data Type<sup>623</sup>

*opaque\_data\_type* *distinct\_data\_type*

Complex Data Type<sup>624</sup>

| Element                   | Description   | Restrictions   | Syntax                                  |
|---------------------------|---|--|---|
| <i>distinct_data_type</i> | Name of a distinct data type                        | The distinct data type must already exist in the database  | <a href="#">Identifier on page 1456</a> |
| <i>opaque_data_type</i>   | Name of an opaque data type                         | The opaque data type must already exist in the database  | <a href="#">Identifier on page 1456</a> |
| <i>slv_name</i>           | Name of a statement local variable you are defining | The <i>slv_name</i> is valid only for the life of the statement, and must be unique within the statement | <a href="#">Identifier on page 1456</a> |

You can declare an SLV in a call to a user-defined function if both of the following conditions are true:

- The UDF has one or more OUT or INOUT parameters
- The SLV is declared when the UDF is invoked in the WHERE clause of a query.

The SLV declaration in the WHERE clause assigns the value of an OUT or INOUT parameter to the SLV, with the sharp (#) symbol between the identifier of the SLV and its declared data type. The UDF can be written in the SPL, C, or Java™ language. For example, if you register a function with the following CREATE FUNCTION statement, you can assign the value of its **y** parameter, which is an OUT parameter, to an SLV in a WHERE clause:

```
CREATE FUNCTION find_location(a FLOAT, b FLOAT, OUT y INTEGER)
RETURNING VARCHAR(20)
EXTERNAL NAME "/usr/lib/local/find.so"
LANGUAGE C;
```

In this example, **find\_location()** accepts two FLOAT values that represent a latitude and a longitude and return the name of the nearest city with an extra value of type INTEGER that represents the population rank of the city.

623. See [Built-In Data Types on page 1164](#)

624. See [Complex Data Type on page 1186](#)

You can now call `find_location()` in a WHERE clause:

```
SELECT zip_code_t FROM address
WHERE address.city = find_location(32.1, 35.7, rank # INT)
AND rank < 101;
```

The function expression passes two FLOAT values to `find_location()` and declares an SLV named `rank` of type INT. In this case, `find_location()` will return the name of the city nearest latitude 32.1 and longitude 35.7 (which might be a heavily populated area) whose population rank is between 1 and 100. The statement then returns the zip code that corresponds to that city.

The SLV can be declared only in a call to the UDF in the WHERE clause of the SELECT statement. The scope of reference of the SLV includes other parts of the same SELECT statement. The following SELECT statement, however, is *invalid* because the SLV declaration is in the projection list of the Projection clause, rather than in the WHERE clause:

```
-- invalid SELECT statement
SELECT title, contains(body, 'dog and cat', rank # INT), rank
FROM documents;
```

The data type that you specify when you declare the SLV must be the same data type as the corresponding OUT or INOUT parameter in the CREATE FUNCTION statement. If you use different but compatible data types, such as INTEGER and FLOAT, the database server automatically performs the cast between the data types.

SLVs share the name space with UDR variables and the column names of the table involved in the SQL statement. Therefore, the database uses the following descending order of precedence to resolve name conflicts among the following objects:

- UDR variables
- Column names
- SLVs

After the call to the UDF assigns the value of an OUT or INOUT parameter to the SLV, you can reference the SLV in other parts of the same query. For more information, see [Statement-Local Variable Expressions on page 1365](#).

## Statement-Local Variable Expressions

The Statement-Local Variable Expression specifies a statement-local variable (SLV) that you can use elsewhere in the same SELECT statement.

Statement-Local Variable Expressions

*SLV\_variable*

| Element             | Description  | Restrictions   | Syntax                                  |
|---------------------|--|--|---|
| <i>SLV_variable</i> | Statement-local variable (SLV) assigned in a call to a user-defined function in the same query | The <i>SLV_variable</i> exists only while the query is executing. Its name must be unique within the query | <a href="#">Identifier on page 1456</a> |

You define an SLV in the call to a user-defined function in the WHERE clause of the SELECT statement. This user-defined function must be defined with one or more OUT or INOUT parameters. The call to the user-defined function assigns the value of the OUT or INOUT parameters to the SLVs. For more information, see [Statement-Local Variable Declaration on page 1364](#).

Once the user-defined function assigns its OUT or INOUT parameters to the SLVs, you can use these values in other parts of the same SELECT statement, subject to the following scope-of-reference rules:

- The SLV is *read-only* throughout the query (or subquery) in which it is defined.
- The scope of an SLV extends from the query in which the SLV is defined down into all nested subqueries.
- In nested queries, the scope of an SLV does not extend upwards.

In other words, if a query contains one or more subqueries, an SLV that is defined in the query is also visible to all the subqueries of that query. But if the SLV is defined in the subquery, it is not visible to the parent query.

- In queries that include the UNION operator, the SLV is only visible in the query in which it is defined.

The SLV is not visible to any other queries specified in the UNION.

- For INSERT, DELETE, and UPDATE statements, an SLV is not visible outside the SELECT portion of the statement.

Within this SELECT portion of a DML statement, all the above scoping rules apply.

**Important:** A statement-local variable is in scope only for the duration of a single SQL statement.

The following SELECT statement calls the **find\_location()** function in a WHERE clause and defines the **rank** SLV. Here **find\_location()** accepts two values that represent a latitude and a longitude and return the name of the nearest city with an extra value of type INTEGER that represents the population rank of the city.

```
SELECT zip_code_t FROM address
WHERE address.city = find_location(32.1, 35.7, rank # INT)
AND rank < 101;
```

When execution of the **find\_location()** function completes successfully, the function has initialized the **rank** SLV. The SELECT then uses this **rank** value in a second WHERE clause condition. In this example, the Statement-Local Variable Expression is the variable **rank** in the second WHERE clause condition:

```
rank < 101
```

The number of OUT and INOUT parameters and SLVs that a UDF can have is not restricted. (Releases of Informix® earlier than Version 9.4 restricted user-defined functions to a single OUT parameter and no INOUT parameters, thereby restricting the number of SLVs to no more than one.)

If the user-defined function that initializes the SLVs is *not* executed in an iteration of the statement, the SLVs each have a value of NULL. Values of SLVs do not persist across iterations of the statement. At the start of each iteration, the database server sets the SLV values to NULL.

The following partial statement calls two user-defined functions with OUT parameters, whose values are referenced with the SLV names **out1** and **out2**:

```
SELECT...
WHERE func_2(x, out1 # INTEGER) < 100
```

```

AND (out1 = 12 OR out1 = 13)
AND func_3(a, out2 # FLOAT) = "SAN FRANCISCO"
AND out2 = 3.1416;

```

If a function assigns one or more OUT or INOUT parameter values from another database of the local database server to SLVs, the values must be of built-in data types, or DISTINCT data types whose base types are built-in data types (and that you cast explicitly to built-in data types), or must be opaque UDTs that you cast explicitly to built-in data types. All the opaque UDTs, DISTINCT types, type hierarchies, and casts must be defined exactly the same way in all of the participating databases.

For more information on how to write a user-defined function with OUT or INOUT parameters, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

## Aggregate Expressions

An aggregate expression uses an aggregate function to summarize selected database data. The built-in aggregate functions have the following syntax.

Aggregate Expressions

**COUNT(\*)**

**AVG COUNT MAX MIN SUM RANGE STDEV VARIANCE**

(

Aggregate Scope Qualifiers)

**ALL**

Subset of Expression<sup>625</sup>

)

User-Defined Aggregates<sup>626</sup>

Aggregate Scope Qualifiers

**ALL**

**DISTINCT UNIQUE**

*table . alias . view . synonym .*

*column*

| Element  | Description  | Restrictions   | Syntax                                  |
|--|--|--|---|
| <i>column</i>  | Column to which aggregate function is applied              | See headings for individual keywords on pages that follow                        | <a href="#">Identifier on page 1456</a> |
| <i>alias,</i><br><i>synonym,</i><br><i>table, view</i> | Synonym, table, view, or alias that contains <i>column</i> | <i>Synonym</i> and the <i>table</i> or <i>view</i> to which it points must exist | <a href="#">Identifier on page 1456</a> |

625. See [Subset of Expressions Valid in an Aggregate Expression on page 1369](#)

626. See [User-Defined Aggregates on page 1368](#)

You cannot use an aggregate expression in a condition that is part of a WHERE clause unless you use the aggregate expression within a subquery. You cannot apply an aggregate function to a BYTE or TEXT column. For other general restrictions, see [Subset of Expressions Valid in an Aggregate Expression on page 1369](#).

An aggregate function returns one value for a set of queried rows. The following examples show aggregate functions in SELECT statements:

```
SELECT SUM(total_price) FROM items WHERE order_num = 1013;

SELECT COUNT(*) FROM orders WHERE order_num = 1001;

SELECT MAX(LENGTH(fname) + LENGTH(lname)) FROM customer;
```

If you use an aggregate function and one or more columns in the projection list of the Projection clause, you must include all the column names that are not used as part of an aggregate or time expression in the GROUP BY clause.

---

## Types of Aggregate Expressions

SQL statements can include *built-in* aggregates and *user-defined* aggregates. The built-in aggregates include all the aggregates shown in the syntax diagram in [Aggregate Expressions on page 1367](#) except for the User-Defined Aggregates category. User-defined aggregates are any new aggregates that the user creates with the CREATE AGGREGATE statement.

## Built-in Aggregates

Built-in aggregates are aggregate functions that are defined by the database server, such as AVG, SUM, and COUNT. These aggregates work only with built-in data types, such as INTEGER and FLOAT. You can extend these built-in aggregates to work with extended data types. To extend built-in aggregates, you must create UDRs that overload several binary operators.

After you overload the binary operators for a built-in aggregate, you can use that aggregate with an extended data type in an SQL statement. For example, if you have overloaded the **plus** operator for the SUM aggregate to work with a specified row type and assigned this row type to the **complex** column of the **complex\_tab** table, you can apply the SUM aggregate to the **complex** column:

```
SELECT SUM(complex) FROM complex_tab;
```

For more information on how to extend built-in aggregates, see *Informix® User-Defined Routines and Data Types Developer's Guide*. For information on how to invoke built-in aggregates, see the descriptions of individual built-in aggregates in the following pages.

## User-Defined Aggregates

A user-defined aggregate is an aggregate that you define to perform an aggregate computation that the database server does not provide. For example, you can create a user-defined aggregate named SUMSQ that returns the sum of the squared values of a specified column. User-defined aggregates can work with built-in data types or extended data types or both, depending on how you define the support functions for the user-defined aggregate.

To create a user-defined aggregate, use the CREATE AGGREGATE statement. In this statement you name the new aggregate and specify the support functions for the aggregate. Once you create the new aggregate and its support functions, you can use the aggregate in SQL statements. For example, if you created the SUMSQ aggregate and specified that it works with the FLOAT data type, you can apply the SUMSQ aggregate to a FLOAT column named **digits** in the **test** table:

```
SELECT SUMSQ(digits) FROM test;
```

For more information on how to create user-defined aggregates, see [CREATE AGGREGATE statement on page 195](#) and the discussion of user-defined aggregates in *Informix® User-Defined Routines and Data Types Developer's Guide*. For information on how to invoke user-defined aggregates, see [User-Defined Aggregates on page 1380](#).

---

## Subset of Expressions Valid in an Aggregate Expression

As indicated in the diagrams for [Aggregate Expressions on page 1367](#) and [User-Defined Aggregates on page 1380](#), not all expressions are available when you use an aggregate expression. The argument of an aggregate function, for example, cannot itself contain an aggregate function. You cannot use aggregate functions in the following contexts:

- In a WHERE clause, but with these two exceptions:
  - unless the aggregate is specified in the Projection clause of a subquery within the WHERE clause,
  - or unless the aggregate is on a correlated column from a parent query, and the WHERE clause is in a subquery within a HAVING clause.
- As an argument to an aggregate function.

The following nested aggregate expression is not valid:

```
MAX (AVG (order_num))
```

- On a column of any of the following data types:
  - Large object (BLOB, BYTE, CLOB, TEXT)
  - Collection data types (LIST, MULTISSET, SET)
  - ROW data types (named or unnamed)
  - OPAQUE data types (except with user-defined aggregate functions that support opaque types).

You cannot use a column that is a collection data type as an argument to the following aggregate functions:

- **AVG**
- **SUM**
- **MIN**
- **MAX**

Expression or *column* arguments to built-in aggregates (except for **COUNT**, **MAX**, **MIN**, and **RANGE**) must return numeric or INTERVAL data types, but **RANGE** also accepts DATE and DATETIME arguments.

For **SUM** and **AVG**, you cannot use the difference between two DATE values directly as the argument to an aggregate, but you can use DATE differences as operands within arithmetic expression arguments. For example:

```
SELECT . . . AVG(ship_date - order_date);
```

returns error -1201, but the following equivalent expression is valid:

```
SELECT . . . AVG((ship_date - order_date)*1);
```

The following query fragment uses valid syntax to declare aliases for two column expressions:

```
SELECT . . .
    SUM(orders.ship_charge) as o2,
    COUNT(DISTINCT
        CASE WHEN orders.backlog MATCHES 'n'
             THEN orders.order_num END ) AS o3,
    . . .
```

Here the argument to **SUM** is a MONEY(6) column value, and the **COUNT DISTINCT** aggregate takes a **CASE** expression as its argument.

## Including or excluding duplicates in the result set

You can use the ALL, DISTINCT, or UNIQUE keywords to qualify the scope of an aggregate function.

If you include an aggregate scope qualifier, it must be the first item in the argument list.

The ALL keyword specifies that all values selected from the column or expression, including any duplicate values, are used in the calculation. Because ALL is the default scope for aggregate functions, the following two aggregate expressions are equivalent, and their return value is based on the value of all qualifying rows in the **ship\_weight** column:

```
AVG(ship_weight)
AVG(ALL ship_weight)
```

Including the DISTINCT keyword as the first argument to the aggregate function restricts its subsequent arguments to unique values from the specified column. The UNIQUE and DISTINCT keywords are synonyms in this context. The following two aggregate expressions are equivalent, and their return value is based on the set of unique values in qualifying rows of the **ship\_weight** column:

```
AVG(DISTINCT ship_weight)
AVG(UNIQUE ship_weight)
```

If several qualifying rows have the same **ship\_weight** value, only one instance of that value is included in calculating the value of the aggregate.

If a query includes the DISTINCT or UNIQUE keyword (rather than the ALL keyword or no keyword) in the Projection clause whose Select list also includes an aggregate function whose argument list begins with the DISTINCT or UNIQUE keyword, the database server issues an error, as in the following example: .

```
SELECT DISTINCT AVG(DISTINCT ship_weight)
    FROM orders;
```

That is, it is not valid in the same query for both the Projection clause and for an aggregate function to restrict the result set to unique values.

If the Projection clause does not specify the **DISTINCT** or **UNIQUE** keyword of the **SELECT** statement, however, the query can include one or more aggregate functions that each includes the **DISTINCT** or **UNIQUE** keyword as the first specification in the argument list, as in the following example:

```
SELECT AVG(UNIQUE ship_weight), COUNT (DISTINCT customer_num)
FROM orders;
```

## AVG Function

The **AVG** function returns the average of all values in the specified column or expression.

You can apply the **AVG** function only to number columns. The query in the following example finds the average price of a helmet:

```
SELECT AVG(unit_price) FROM stock WHERE stock_num = 110;
```

The return value is calculated by dividing the sum of **unit\_price** values by the cardinality of the qualifying rows.

If you use the **DISTINCT** or **UNIQUE** keyword as the first argument, the average (meaning the *mean*) is calculated from only the distinct values in the specified column or expression. In the following example, only one instance of any duplicate values is included when the sum and the cardinality are calculated:

```
SELECT AVG(DISTINCT unit_price) FROM stock WHERE stock_num = 110;
```

If the data set included no duplicate values, both examples above return the same **AVG** value.

**NULL** values are ignored unless every value in the column or expression is **NULL**. If every value is **NULL**, the **AVG** function returns **NULL** for that column or expression.

---

## Overview of COUNT Functions

The **COUNT** function is actually a set of functions that enable you to count column values in different ways, according to arguments after the **COUNT** keyword.

Each form of the **COUNT** function is explained in the following subsections. For a comparison of the different forms of the **COUNT** function, see [Arguments to the COUNT Functions on page 1373](#).

### COUNT(\*) function

The **COUNT (\*)** function returns the number of rows that satisfy the **WHERE** clause of a **SELECT** statement.

The following example finds how many rows in the **stock** table have the value **HRO** in the **manu\_code** column:

```
SELECT COUNT(*) FROM stock WHERE manu_code = 'HRO';
```

The following example queries one of the System Monitoring Interface (SMI) tables to find the number of extents in the **customer** table:

```
SELECT COUNT(*) FROM sysextents WHERE dbs_name = 'stores' AND tabname = customer";
```

You can use **COUNT(\*)** as the Projection clause in queries of this general format to obtain information from the SMI tables. For information about **sysextents** and other SMI tables, see the chapter that describes the **sysmaster** database.

If the SELECT statement does not have a WHERE clause, the **COUNT (\*)** function returns the total number of rows in the table. The following example finds how many rows are in the **stock** table:

```
SELECT COUNT(*) FROM stock;
```

If the SELECT statement contains a GROUP BY clause, the **COUNT (\*)** function reflects the number of values in each group. The following example is grouped by the first name; the rows are selected if the database server finds more than one occurrence of the same name:

```
SELECT fname, COUNT(*) FROM customer GROUP BY fname
HAVING COUNT(*) > 1;
```

If the value of one or more rows is NULL, the **COUNT (\*)** function includes the NULL columns in the count unless the WHERE clause explicitly omits them.

#### Related reference

[OLAP window aggregate functions on page 1400](#)

## COUNT DISTINCT and COUNT UNIQUE functions

The **COUNT DISTINCT** and **COUNT UNIQUE** functions return unique values.

The **COUNT DISTINCT** function returns the number of unique values in the column or expression, as the following example shows.

```
SELECT COUNT (DISTINCT item_num) FROM items;
```

If the **COUNT DISTINCT** function encounters NULL values, it ignores them unless every value in the specified column is NULL. If every column value is NULL, the **COUNT DISTINCT** function returns zero (0).

The **UNIQUE** keyword has the same meaning as the **DISTINCT** keyword in **COUNT** functions. The **UNIQUE** keyword instructs the database server to return the number of unique non-NULL values in the column or expression. The following example calls the **COUNT UNIQUE** function, but it is equivalent to the preceding example that calls the **COUNT DISTINCT** function:

```
SELECT COUNT (UNIQUE item_num) FROM items;
```

If the Projection clause does not specify the **DISTINCT** or **UNIQUE** keyword of the SELECT statement, the query can include multiple COUNT functions that each includes the **DISTINCT** or **UNIQUE** keyword as the first specification in the argument list, as in the following example:

```
SELECT COUNT (UNIQUE item_num), COUNT (DISTINCT order_num) FROM items;
```

**Related reference**

[OLAP window aggregate functions on page 1400](#)

## COUNT column Function

The **COUNT** *column* function returns the total number of non-NULL values in the column or expression, as the following example shows:

```
SELECT COUNT (item_num) FROM items;
```

The ALL keyword can precede the specified column name for clarity, but the query result is the same whether you include the ALL keyword or omit it.

The following example shows how to include the ALL keyword in the **COUNT** *column* function:

```
SELECT COUNT (ALL item_num) FROM items;
```

## Arguments to the COUNT Functions

The **COUNT** function accepts as its argument the same expressions that are allowed in the argument list of other built-in aggregate functions, as well as the asterisk (\*) notation that only **COUNT** supports. The following categories of built-in expressions are supported as the argument to **COUNT**, as illustrated in the following examples:

- Arithmetic Expressions

```
COUNT(times(informix.sysfragments.evalpos,2))
SELECT COUNT(a+1), COUNT(2*a), COUNT(5/a), COUNT(times(a, 2)) FROM myTable;
```

- Bitwise Logical Functions

```
COUNT(BITAND(informix.systables.flags,1))
SELECT COUNT(BITAND(a,1)), COUNT(BITOR(8, 20)), COUNT(BITXOR(41, 33)),
COUNT(BITANDNOT(20,-20)), COUNT(BITNOT(8)) FROM myTable;
```

- Cast Expressions

```
COUNT(NULL::int)
```

- Conditional Expressions

```
COUNT(CASE WHEN stock.description = "baseball gloves" THEN 1 ELSE NULL END)
SELECT COUNT(CASE WHEN s=14 THEN 1 ELSE NULL END) AS cnt14 FROM all_types;
SELECT COUNT(NVL (ch, 'Addr unk')) FROM all_types;
SELECT COUNT(NULLIF(ch, NULL)) FROM all_types;
```

- Constant Expressions

```
COUNT(CURRENT_ROLE)
COUNT(DATETIME (2007-12-6) YEAR TO DAY)
SELECT COUNT("XX"), COUNT(99),COUNT("t") FROM sysmaster:sysdual;
```

```

SELECT COUNT(SET{6, 9, 9, 4}) FROM sysmaster:sysdual;
SELECT COUNT("ROW(7, 3, 6.0, 2.0)") FROM sysmaster:sysdual;
SELECT COUNT(USER), COUNT(CURRENT), COUNT(SYSDATE) from sysmaster:sysdual;
SELECT COUNT(CURRENT_ROLE), COUNT(DEFAULT_ROLE) from sysmaster:sysdual;
SELECT COUNT(DBSERVERNAME), COUNT(TODAY), COUNT(CURRENT) from sysmaster:sysdual;
SELECT COUNT(DATETIME (2007-12-6) YEAR TO DAY) from sysmaster:sysdual;
SELECT COUNT(INTERVAL (16) DAY TO DAY) FROM sysmaster:sysdual;
SELECT COUNT(5 UNITS DAY) FROM sysmaster:sysdual;

```

- Function Expressions

```

COUNT(LENGTH ('abc') + LENGTH (stock.description)
COUNT(DBINFO('sessionid'))
COUNT(user_proc()) --> Here proc() is a user-defined routine.

```

- Column Expressions

```

COUNT(informix.sysfragauth.fragment)

```

You can also use the asterisk (\*) character, or a column name, or a column name with the ALL, DISTINCT, or UNIQUE aggregate scope qualifiers as the argument to the **COUNT** function to retrieve different types of information about a table. The table below summarizes the meaning of each of the following forms of the **COUNT** function with an asterisk or column name argument.

| COUNT Function                       | Description   |
|--------------------------------------|---|
| COUNT (*)                            | Returns the number of rows that satisfy the query. If you do not specify a WHERE clause, this function returns the total number of rows in the table. |
| COUNT (DISTINCT) or COUNT (UNIQUE)   | Returns the number of unique non-NULL values in the specified column  |
| COUNT (column) or COUNT (ALL column) | Returns the total number of non-NULL values in the specified column   |

Some examples can help to show the differences among the various forms of the **COUNT** function that reference a column. Most of the following examples query against the **ship\_instruct** column of the **orders** table in the **stores\_demo** demonstration database. For information on the schema of the **orders** table and the data values in the **ship\_instruct** column, see the description of the demonstration database in the *Informix® Guide to SQL: Reference*.

## Examples of the COUNT(\*) Function

In the following example, the user wants to know the total number of rows in the **orders** table. So the user calls the **COUNT(\*)** function in a SELECT statement without a WHERE clause:

```

SELECT COUNT(*) AS total_rows FROM orders;

```

The following table shows the result of this query.

| total_rows |
|------------|
| 23         |

In the following example, the user wants to know how many rows in the **orders** table have a NULL value in the **ship\_instruct** column. The user calls the **COUNT(\*)** function in a SELECT statement with a WHERE clause, and specifies the IS NULL condition in the WHERE clause:

```
SELECT COUNT (*) AS no_ship_instruct FROM orders
WHERE ship_instruct IS NULL;
```

The following table shows the result of this query.

| <b>no_ship_instruct</b> |
|-------------------------|
| 2                       |

In the following example, the user wants to know how many rows in the **orders** table have the value `express` in the **ship\_instruct** column. So the user calls the **COUNT(\*)** function in the projection list and specifies the equals (=) relational operator in the WHERE clause.

```
SELECT COUNT (*) AS ship_express FROM ORDERS
WHERE ship_instruct = 'express';
```

The following table shows the result of this query.

| <b>ship_express</b> |
|---------------------|
| 6                   |

## Examples of the COUNT DISTINCT Function

In the next example, the user wants to know how many unique non-NULL values are in the **ship\_instruct** column of the **orders** table. The user calls the **COUNT DISTINCT** function in the projection list of the SELECT statement:

```
SELECT COUNT(DISTINCT ship_instruct) AS unique_notnulls
FROM orders;
```

The following table shows the result of this query.

| <b>unique_notnulls</b> |
|------------------------|
| 16                     |

## Examples of the COUNT column Function

In the following example the user wants to know how many non-NULL values are in the **ship\_instruct** column of the **orders** table. The user invokes the **COUNT(column)** function in the Projection list of the SELECT statement:

```
SELECT COUNT(ship_instruct) AS total_notnulls FROM orders;
```

The following table shows the result of this query.

---

| <b>total_notnulls</b> |
|-----------------------|
| 21                    |

---

A similar query for non-NULL values in the **ship\_instruct** column can include the ALL keyword in the parentheses that follow the COUNT keyword:

```
SELECT COUNT(ALL ship_instruct) AS all_notnulls FROM orders;
```

The following table shows that the query result is the same whether you include or omit the ALL keyword (because ALL is the default).

---

| <b>all_notnulls</b> |
|---------------------|
| 21                  |

---

## MAX Function

The **MAX** function returns the largest value in the specified column or expression.

Using the DISTINCT keyword does not change the results. The query in the following example finds the most expensive item that is in stock but has not been ordered:

```
SELECT MAX(unit_price) FROM stock
WHERE NOT EXISTS (SELECT * FROM items
WHERE stock.stock_num = items.stock_num AND
stock.manu_code = items.manu_code);
```

NULLs are ignored unless every value in the column is NULL. If every column value is NULL, the **MAX** function returns a NULL for that column.

---

### Related reference

[OLAP window aggregate functions on page 1400](#)

## MIN Function

The **MIN** function returns the lowest value in the column or expression. Using the DISTINCT keyword does not change the results. The following example finds the least expensive item in the **stock** table:

```
SELECT MIN(unit_price) FROM stock;
```

NULL values are ignored unless every value in the column is NULL. If every column value is NULL, the **MIN** function returns a NULL for that column.

---

**Related reference**[OLAP window aggregate functions on page 1400](#)

## SUM Function

The **SUM** function returns the sum of all the values in the specified column or expression, as the following example shows:

```
SELECT SUM(total_price) FROM items WHERE order_num = 1013;
```

If you include the **DISTINCT** or **UNIQUE** keyword, the returned sum is for only distinct values in the column or expression:

```
SELECT SUM(DISTINCT total_price) FROM items WHERE order_num = 1013;
```

**NULL** values are ignored unless every value in the column is **NULL**. If every column value is **NULL**, the **SUM** function returns a **NULL** for that column. You cannot use the **SUM** function with a non-numeric column.

---

**Related reference**[OLAP window aggregate functions on page 1400](#)

## RANGE Function

The **RANGE** function returns the range of values for a numeric column expression argument.

It calculates the difference between the maximum and the minimum values, as follows:

```
range(expr) = max(expr) - min(expr);
```

You can apply the **RANGE** function only to numeric columns. The following query finds the range of ages for a population:

```
SELECT RANGE(age) FROM u_pop;
```

As with other aggregates, the **RANGE** function applies to the rows of a group when the query includes a **GROUP BY** clause, as the next example shows:

```
SELECT RANGE(age) FROM u_pop GROUP BY birth;
```

Because **DATE** values are stored internally as integers, you can use the **RANGE** function on **DATE** columns. With a **DATE** column, the return value is the number of days between the earliest and latest dates in the column.

**NULL** values are ignored unless every value in the column is **NULL**. If every column value is **NULL**, the **RANGE** function returns a **NULL** for that column.

**Important:** All computations for the **RANGE** function are performed in 32-digit precision, which should be sufficient for many sets of input data. The computation, however, loses precision or returns incorrect results when all of the input data values have 16 or more digits of precision.

---

#### Related reference

[OLAP window aggregate functions on page 1400](#)

## STDEV Function

The **STDEV** function computes the standard deviation of a data set, which is the square root of the **VARIANCE** function. You can apply the **STDEV** function only to numeric columns. The next query finds the standard deviation:

```
SELECT STDEV(age) FROM u_pop WHERE u_pop.age > 0;
```

As with the other aggregates, the **STDEV** function applies to the rows of a group when the query includes a **GROUP BY** clause, as this example shows:

```
SELECT STDEV(age) FROM u_pop GROUP BY birth WHERE STDEV(age) > 0;
```

NULL values are ignored unless every value in the specified column is NULL. If every column value is NULL, **STDEV** returns a NULL for that column.

**Important:** All computations for the **STDEV** function are performed in 32-digit precision, which should be sufficient for many sets of input data. The computation, however, loses precision or returns incorrect results when all of the input data values have 16 or more digits of precision.

You cannot use this function on columns of type DATE.

Within a **SELECT** Statement with **GROUP BY** clause, **STDEV** returns a zero variance for a count of 1. You can omit this special case through appropriate query construction (for example, `HAVING COUNT(*) > 1`). Otherwise, a data set that has only a few cases might block the rest of the query result.

---

#### Related reference

[OLAP window aggregate functions on page 1400](#)

## VARIANCE Function

The **VARIANCE** function returns an estimate of the population variance, as the standard deviation squared.

**VARIANCE** calculates the following value:

```
(SUM(Xi2) - (SUM(Xi)2)/N)/(N - 1)
```

In this formula,

- $\bar{x}_i$  is each value in the column,
- and  $N$  is the total number of non-NULL values in the column (unless all values are NULL, in which case the variance is logically undefined, and the **VARIANCE** function returns NULL).

You can apply the **VARIANCE** function only to numeric columns.

The following query estimates the variance of **age** values for a population:

```
SELECT VARIANCE(age) FROM u_pop WHERE u_pop.age > 0;
```

As with the other aggregates, the **VARIANCE** function applies to the rows of a group when the query includes a GROUP BY clause, as in this example:

```
SELECT VARIANCE(age) FROM u_pop GROUP BY birth
WHERE VARIANCE(age) > 0;
```

As previously noted, **VARIANCE** ignores NULL values unless every qualified row is NULL for a specified column. If every value is NULL, then **VARIANCE** returns a NULL result for that column. (This typically indicates missing data, and is not necessarily a good estimate of underlying population variance.)

If  $N$ , the total number of qualifying non-NULL column values, equals 1, then the **VARIANCE** function returns zero (another implausible estimate of the true population variance). To omit this special case, you can modify the query. For example, you might include a `HAVING COUNT(*) > 1` clause.

**Important:** All calculations for the **VARIANCE** function are performed in 32-digit precision, which should be sufficient for many sets of input data. The calculation, however, loses precision or returns incorrect results when all of the input data values have 16 or more digits of precision.

Although DATE values are stored internally as an integer, you cannot use the **VARIANCE** function on columns of data type DATE.

---

[OLAP window aggregate functions on page 1400](#)

## Error Checking in ESQL/C

Aggregate functions always return exactly one row. If no rows are selected, the function returns a NULL. You can use the **COUNT (\*)** function to determine whether any rows were selected, and you can use an indicator variable to determine whether any selected rows were empty. Fetching a row with a cursor that is associated with an aggregate function always returns one row; hence, 100 for end of data is never returned into the **sqlcode** variable for a first FETCH attempt.

You can also use the GET DIAGNOSTICS statement for error checking.

## Summary of Aggregate Function Behavior

An example can help to summarize the behavior of the aggregate functions. Assume that the **testtable** table has a single INTEGER column that is named **num**. The contents of this table are as follows.

| <b>num</b> |
|------------|
| 2          |
| 2          |
| 2          |
| 3          |
| 3          |
| 4          |
| (NULL)     |

You can use aggregate functions to obtain information about the **num** column and the **testtable** table. The following query uses the **AVG** function to obtain the average of all the non-NULL values in the **num** column:

```
SELECT AVG(num) AS average_number FROM testtable;
```

The following table shows the result of this query.

| <b>average_number</b> |
|-----------------------|
| 2.666666666666667     |

You can use the other aggregate functions in SELECT statements that are similar to the preceding example. If you enter a series of SELECT statements that have different aggregate functions in the projection list and do not include a WHERE clause, you receive the results that the following table shows.

| <b>Function</b>  | <b>Results</b>    | <b>Function</b> | <b>Results</b> |
|------------------|-------------------|-----------------|----------------|
| COUNT (*)        | 7                 | MAX             | 4              |
| COUNT (DISTINCT) | 3                 | MAX(DISTINCT)   | 4              |
| COUNT (ALL num)  | 6                 | MIN             | 2              |
| COUNT ( num )    | 6                 | MIN(DISTINCT)   | 2              |
| AVG              | 2.666666666666667 | RANGE           | 2              |
| AVG (DISTINCT)   | 3.000000000000000 | SUM             | 16             |
| STDEV            | 0.74535599249993  | SUM(DISTINCT)   | 9              |
| VARIANCE         | 0.555555555555556 |                 |                |

## User-Defined Aggregates

You can create your own aggregate expressions with the CREATE AGGREGATE statement and then invoke these aggregates wherever you can invoke the built-in aggregates.

The following diagram shows the syntax for invoking a user-defined aggregate.

User-Defined Aggregates

```
aggregate(
```

```
ALL
```

```
DISTINCT UNIQUE
```

```
table. view. synonym.
```

```
column
```

```
ALL
```

```
Subset of Expression627
```

```
,setup_expr
```

```
)
```

| Element                     | Description  | Restrictions  | Syntax                                     |
|-----------------------------|--|---|--|
| <i>aggregate</i>            | Name of the user-defined aggregate to invoke                                 | The <i>aggregate</i> and the support functions defined for <i>aggregate</i> must exist                                  | <a href="#">Identifier on page 1456</a>    |
| <i>column</i>               | Name of a column within <i>table</i>   | Must exist and have a numeric data type   | <a href="#">Quoted String on page 1424</a> |
| <i>setup_expr</i>           | Set-up expression that customizes <i>aggregate</i> for a specific invocation | Cannot be a lone host variable. Any columns referenced in <i>setup_expr</i> must be in the GROUP BY clause of the query | <a href="#">Expression on page 1193</a>    |
| <i>synonym, table, view</i> | Synonym, table, or view in which <i>column</i> occurs                        | The <i>synonym</i> and the table or view to which it points must exist  | <a href="#">Identifier on page 1456</a>    |

Use the DISTINCT or UNIQUE keywords to specify that the user-defined aggregate is to be applied only to unique values in the named column or expression. Use the ALL keyword to specify that the aggregate is to be applied to all values in the named column or expression.

If you omit the DISTINCT, UNIQUE, and ALL keywords, ALL is the default. For further information on the DISTINCT, UNIQUE, and ALL keywords, see [Including or excluding duplicates in the result set on page 1370](#).

When you specify a setup expression, this value is passed to the **INIT** support function that was defined for the user-defined aggregate in the CREATE AGGREGATE statement.

In the following example, you apply the user-defined aggregate named **my\_avg** to all values of the **quantity** column in the **items** table:

```
SELECT my_avg(quantity) FROM items
```

627. See [Subset of Expressions Valid in an Aggregate Expression on page 1369](#)

In the following example, you apply the user-defined aggregate named **my\_sum** to unique values of the **quantity** column in the **items** table. You also supply the value **5** as a setup expression. This value might specify that the initial value of the sum that **my\_avg** will compute is **5**.

```
SELECT my_sum(DISTINCT quantity, 5) FROM items
```

In the following example, you apply the user-defined aggregate named **my\_max** to all values of the **quantity** column in the remote **items** table:

```
SELECT my_max(remote.quantity) FROM rdb@rserv:items remote
```

If the **my\_max** aggregate is defined as EXECUTEANYWHERE, then the distributed query can be pushed to the remote database server, **rserv**, for execution. If the **my\_max** aggregate is not defined as EXECUTEANYWHERE, then the distributed query scans the remote **items** table and computes the **my\_max** aggregate on the local database server.

You cannot qualify a user-defined aggregate with the name of a remote database server, as the following example shows. In this case, the database server returns an error:

```
SELECT rdb@rserv:my_max(remote.quantity)
FROM rdb@rserv:items remote
```

For further information on user-defined aggregates, see [CREATE AGGREGATE statement on page 195](#) and the discussion of user-defined aggregates in *Informix® User-Defined Routines and Data Types Developer's Guide*.

## Aggregate expressions in grid queries

Aggregate expressions in grid queries require the database server that issues the grid query to combine aggregate results from multiple grid servers.

Grid queries are distributed SELECT statements that return the logical UNION or UNION ALL on qualifying rows of database tables that have identical schemas in databases of a grid. Grid queries are described in the [GRID clause on page 809](#) topic and in the .

Aggregate expressions in grid queries require the database server that issues the Grid query to combine aggregate results from multiple grid servers. Because the Grid query that you specify is converted into a UNION or UNION ALL query across multiple grid servers, each aggregate is calculated independently on each participating server within the specified grid or region. These individual aggregates are returned to the database server that issued the grid query, which calculates their combined UNION or UNION ALL value.

In order to calculate a global aggregation from these individual aggregates, the grid query must be a subquery. For example, suppose we wanted to see for the southeast region (**SW\_USA** in the following example) the total sales and the average sale. Because it is not correct to take the average of a group of averages if the number of qualifying rows varies across data sets within the grid, the correct grid query needs to resemble this:

```
SELECT SUM(amt) AS total_sales ,
       SUM(amt) / SUM(cnt) AS avg_sale FROM
(
  SELECT COUNT(*) cnt, SUM(amt) amt
  FROM sales GRID ALL 'SW_USA'
);
```

| total_sales | avg_sale |
|-------------|----------|
| \$8300.00   | \$103.75 |

In this example, the projection list of the grid query specifies a COUNT(\*) expression (aliased as `cnt`) and an aggregate amount `SUM(amt)` (aliased as `amt`) from the **sales** table of each grid server within the southeast region (encoded as `'SW_USA'`). Using these values from each of the remote grid servers, the local grid server can calculate an average for the region. This is accomplished by adding up the total sales by evaluating the expression `SUM(amt)` and dividing that value by the total count `SUM(cnt)`, where `cnt` and `amt` are columns in the result set of the grid subquery.

Note that the GRID ALL keywords specify a UNION ALL of the qualifying rows from each participating grid server, to avoid eliminating duplicate rows.

---

## OLAP window expressions

You can include On-Line Analytical Processing (OLAP) expressions in a SELECT statement to operate on subsets of the rows in the result set of a query or subquery. You can use OLAP window expressions to examine subsets of the qualifying rows for patterns, trends, or exceptions in the data.

OLAP window expressions allow application developers to compose analytic business queries more easily and efficiently. For example, moving averages and moving sums can be calculated over various intervals. Aggregations and ranks can be reset as selected column values change. Complex ratios can be expressed in simple terms.

### Syntax

OLAP window expressions

OLAP numbering function OVER clause for numbering function <sup>628</sup>

OLAP ranking function OVER clause for ranking functions <sup>629</sup>

OLAP aggregation function OVER clause for aggregation functions <sup>630</sup>

OLAP window expressions are valid in these clauses of the SELECT statement:

- The Select list of the Projection clause
- The ORDER BY clause of the SELECT statement
- Subquery specifications in the Projection clause

OLAP window expressions require an OLAP window function and an OVER clause.

628. See [OLAP numbering function expression on page 1386](#).

629. See [OLAP ranking function expressions on page 1388](#).

630. See [OLAP aggregation function expressions on page 1396](#).

### **OLAP window function**

The OLAP window function identifies an operation for the database server to perform on rows in the query result set. OLAP window functions fit into the following functional categories:

- The OLAP numbering function assigns a unique row number to each row:
  - ROW\_NUMBER and ROWNUMBER, which are synonyms
- OLAP ranking functions assign a rank to each row:
  - LAG
  - LEAD
  - RANK
  - DENSE\_RANK
  - PERCENT\_RANK
  - CUME\_DIST
  - NTILE
- OLAP aggregation functions aggregate row data:
  - FIRST\_VALUE
  - LAST\_VALUE
  - RATIO\_TO\_REPORT
  - AVG
  - COUNT
  - MAX
  - MIN
  - RANGE
  - STDEV
  - SUM
  - VARIANCE

### **OVER clause**

The OVER clause defines the result set on which the specified operation is performed. The OVER clause has the following capabilities:

- Define window partitions with the PARTITION BY clause. OLAP window partitions are subsets of the rows in the query result set that are based on the values of one or more column expressions that are listed in the PARTITION BY clause.
- Order rows with the ORDER BY clause. If you include the PARTITION BY clause, you order results within each window partition. Otherwise, you order the whole result.
- Define window frames with the ROWS or RANGE specification for OLAP window aggregation functions. A window frame defines a set of rows within a window partition. The aggregation function operates on the contents of the moving window frame instead of on the whole partition.

For example, the following query contains the OLAP aggregation function SUM:

```

SELECT c,d,
       SUM(d) OVER(
         PARTITION BY a,b
         ORDER BY c,d
         ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING)
FROM table1;

```

The PARTITION BY clause creates window partitions for each set of values of columns **a** and **b**.

The ORDER BY clause orders the data within each window partition by the values of the columns **c** and **d**.

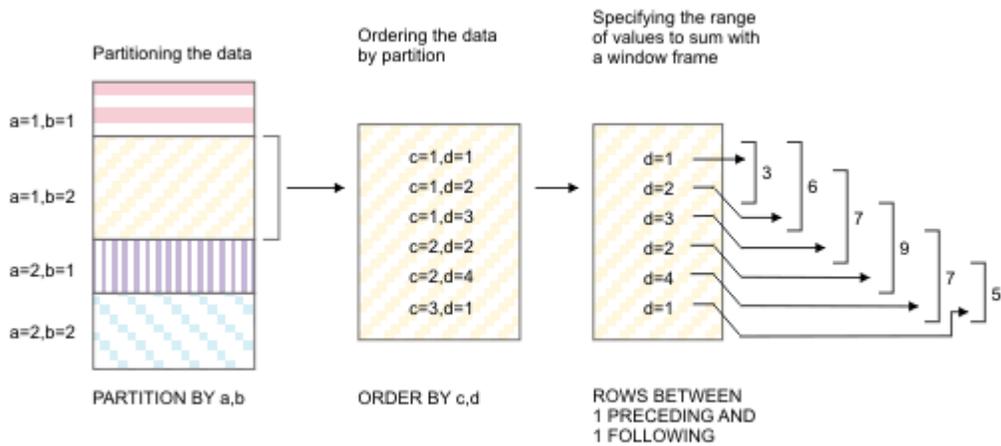

The window frame clause that starts with the ROWS keyword creates a window frame that consists of three rows: the current row, the row that precedes the current row, and the row that follows the current row. The current row is the reference point for the window frame. The following table shows how the window frame moves through the result set as each row becomes the current row in turn.

**Table 31. Window frames in the result set**

| Row number | First frame      | Second frame     | Third frame      | Fourth frame     | Fifth frame      | Sixth frame      |
|------------|------------------|------------------|------------------|------------------|------------------|------------------|
| 1          | Current@ row     | Current@ row - 1 |                  |                  |                  |                  |
| 2          | Current@ row + 1 | Current@ row     | Current@ row - 1 |                  |                  |                  |
| 3          |                  | Current@ row + 1 | Current@ row     | Current@ row - 1 |                  |                  |
| 4          |                  |                  | Current@ row + 1 | Current@ row     | Current@ row - 1 |                  |
| 5          |                  |                  |                  | Current@ row + 1 | Current@ row     | Current@ row - 1 |
| 6          |                  |                  |                  |                  | Current@ row + 1 | Current@ row     |

The SUM function adds the values of **d** column for the three rows for each window partition that is in the scope of the query.

The following illustration shows how the query partitions, orders, and aggregates the data.

The query returns the values of columns **c** and **d** for the single window partition and the sum of up to three values of column **d**:

| c | d | (sum) |
|---|---|-------|
| 1 | 1 | 3     |
| 1 | 2 | 6     |
| 1 | 3 | 7     |
| 2 | 2 | 9     |
| 2 | 4 | 7     |
| 3 | 1 | 5     |

The first value in the **sum** column is the sum of the first and second values (1 + 2 = 3) in the **d** column. No preceding value for the current row exists for the first value.

The second value in the **sum** column is the sum of the first, second, and third values (1 + 2 + 3 = 6) in the **d** column.

The third value in the **sum** column is the sum of the second, third, and fourth values (2 + 3 + 2 = 7) in the **d** column.

The last value in the **sum** column is the sum of the fifth and sixth values (1 + 4 = 5) in the **d** column. No following value for the current row exists for the last value.

[OLAP window functions in the ORDER BY clause of SELECT statements on page 847](#)

## OLAP numbering function expression

The OLAP numbering function expression returns a sequential number for each row in the result set of a single query.

The OLAP numbering function expression is an OLAP window expression that you can include in the Projection list of a SELECT statement, or the ORDER BY clause of a SELECT statement.

**Syntax**

OLAP numbering function expression

**ROW\_NUMBER ROWNUMBER**

( )OVER clause for the numbering function

OVER clause for the numbering function

**OVER**(Window PARTITION clause<sup>631</sup> Window ORDER clause<sup>631</sup>)

**Usage**

The keywords ROW\_NUMBER and ROWNUMBER are synonyms for the same function. This numbering function is like a simplified RANK function that does not require a window ORDER clause and that does not detect duplicate values. The ROW\_NUMBER function always returns a unique value for each row in each OLAP window partition.

The ROW\_NUMBER function takes no argument, but you must include the empty parentheses after the ROW\_NUMBER (or ROWNUMBER) keyword.

The ROW\_NUMBER function returns an unsigned integer for every row in each OLAP partition. The sequence of row numbers in each partition starts with 1, and each successive row is incremented by 1, whether consecutive rows in a window partition have the same or different column values.

If the window PARTITION clause is not specified, the complete result set is numbered from 1 to *n*, where *n* is the number of qualifying rows that the query or subquery returns.

The OLAP window that the OVER clause defines for numbering functions has this syntax:

- The window PARTITION clause is optional. If none is specified, the scope of the numbering function is the entire result set of the query or subquery, rather than partitioned subsets.
- The window ORDER clause is optional. If none is specified, the returned row numbers are based on the default order of the rows as processed by the query. If a window ORDER clause is specified, the ORDER BY specification determines the row number assignments.
- The window Frame clause is not supported for OLAP numbering functions.

If the OVER clause that defines the OLAP window for the ROW\_NUMBER function omits both the window PARTITION clause and window ORDER clause, you must include the empty parentheses after the OVER keyword.

**Example: ROW\_NUMBER function**

The following query partitions the rows in the product table by distinct package types (pkg\_type) and assigns row numbers that restart at 1 for each partition.

```
SELECT ROW_NUMBER()
  OVER(PARTITION BY pkg_type ORDER BY prod_name)
  AS rownum, prod_name, pkg_type
FROM product;
```

| ROWNUM | PROD_NAME             | PKG_TYPE           |
|--------|-----------------------|--------------------|
| 1      | Aroma Sounds CD       | Aroma designer box |
| 2      | Aroma Sounds Cassette | Aroma designer box |
| 1      | Christmas Sampler     | Gift box           |

631. See [OVER clause for OLAP window expressions on page 1405](#)

|     |                       |          |
|-----|-----------------------|----------|
| 2   | Coffee Sampler        | Gift box |
| 3   | Easter Sampler Basket | Gift box |
| 4   | Spice Sampler         | Gift box |
| 5   | Tea Sampler           | Gift box |
| 1   | Aroma Roma            | No pkg   |
| 2   | Aroma baseball cap    | No pkg   |
| 3   | Aroma t-shirt         | No pkg   |
| 4   | Assam Gold Blend      | No pkg   |
| 5   | Assam Grade A         | No pkg   |
| 6   | Breakfast Blend       | No pkg   |
| 7   | Cafe Au Lait          | No pkg   |
| 8   | Coffee Mug            | No pkg   |
| 9   | Colombiano            | No pkg   |
| 10  | Darjeeling Number 1   | No pkg   |
| 11  | Darjeeling Special    | No pkg   |
| 12  | Demitasse Ms          | No pkg   |
| 13  | Earl Grey             | No pkg   |
| ... |                       |          |

Because the window ORDER clause specifies the prod\_name column as the sorting key, in the default (ASC) order, the returned row numbers are based on the alphabetical order of the product names. For example, the three "Aroma" products are numbered 1, 2, and 3 within the "No pkg" partition. (Uppercase letters sort above lowercase in the default ASCII collation.)

## OLAP ranking function expressions

You can include OLAP ranking function expressions to calculate ordinal ranks that can be applied to each row in the partitioned result set of a query or subquery.

OLAP ranking function expressions are OLAP window expressions that you can include in the Projection list of a SELECT statement, or the ORDER BY clause of a SELECT statement.

**Syntax**

OLAP ranking function expressions

OLAP ranking function OVER clause for ranking functions

OLAP ranking function

LAG function<sup>633</sup>

LEAD function<sup>633</sup>

RANK function<sup>634</sup>

DENSE\_RANK function<sup>635</sup>

PERCENT\_RANK function<sup>636</sup>

CUME\_DIST function<sup>637</sup>

NTILE function<sup>638</sup>

OVER clause for ranking functions

**OVER**(Window PARTITION clause<sup>632</sup> Window ORDER clause<sup>632</sup>)

**Usage**

The ranking values that these functions return are dependent on the window ORDER clause within the OVER clause. The ORDER clause defines the columns or expressions that the database server uses to calculate the ranking values.

If you omit the window PARTITION clause, the scope of the ranking function is the entire result set of the query or subquery, rather than partitioned subsets of results.

**LAG and LEAD functions**

The LAG and LEAD functions are OLAP ranking functions that return the value of their *expression* argument for the row at a specified offset from the current row within the current window partition.

632. See [OVER clause for OLAP window expressions on page 1405](#)

633. See [LAG and LEAD functions on page 1389](#)

634. See [RANK function on page 1392](#)

635. See [DENSE\\_RANK function on page 1392](#)

636. See [PERCENT\\_RANK function on page 1393](#)

637. See [CUME\\_DIST function on page 1394](#)

638. See [NTILE function on page 1395](#)

**Syntax**

LAG and LEAD functions

**LAG LEAD***(expression***RESPECT NULLS IGNORE NULLS***,offset**,default*

)

*(expression**,offset**,default*

)

**RESPECT NULLS IGNORE NULLS**OVER clause for Ranking functions<sup>639</sup>

| Element           | Description   | Restrictions  | Syntax  |
|-------------------|---|---|---|
| <i>default</i>    | Value to return if <i>offset</i> goes beyond the scope of the current window partition                      | If <i>default</i> is not specified, the value of NULL is returned for any out-of-scope row.                                     | <a href="#">Column Expressions on page 1219</a> |
| <i>expression</i> | Column name, alias, or constant expression to return for the row at <i>offset</i> rows from the current row | If <i>expression</i> references a column, the column must also be in the select list of the Projection clause.                  | <a href="#">Column Expressions on page 1219</a> |
| <i>offset</i>     | Non-negative integer constant defining an offset from the position of the current row                       | Requires a window PARTITION clause. If zero, specifies the current row. If <i>offset</i> is not specified, the value 1 is used. | Literal integer                                 |

**Usage**

The *expression* argument is required. The data type of the return value from the LAG or LEAD function is the data type of the expression.

Based on the sort order that the window ORDER clause imposes for each window partition, the LEAD and LAG functions return the value of the expression for every row at *offset* rows from the current row:

- For the LAG function, the *offset* indicates the row that precedes the current row by *offset* rows.
- For the LEAD function, the *offset* indicates the row that follows the current row by *offset* rows.

If the OVER clause includes no window PARTITION clause, these functions return the *expression* values for the entire result set of the query.

639. See [OVER clause for OLAP window expressions on page 1405](#)

If a window PARTITION clause is specified, the second argument to the LAG function (*offset*) means *offset* rows before the current row and within the current partition. For the LEAD function, the second argument means *offset* rows after the current row and within the current partition.

For both functions, if *offset* is not specified, the value 1 is used. If you specify the optional third argument (*default*), which can be an expression, its value is returned if the *offset* goes beyond the scope of the current partition. Otherwise, the NULL value is returned. When the third argument is specified, the second argument must also be specified.

## Handling NULL values

In a LAG or LEAD function expression, the optional RESPECT NULLS or IGNORE NULLS keywords can be specified in either of two locations:

- In the argument list
- Immediately following the closing parenthesis that delimits the argument list

The database server issues an exception, however, if you include RESPECT NULLS or IGNORE NULLS in both of these locations within the same LAG or LEAD expression.

The RESPECT NULLS and IGNORE NULLS keywords have these effects:

- If you specify the RESPECT NULLS keywords, rows whose *expression* evaluates to NULL are included when *offset* rows are counted.
- If you specify the IGNORE NULLS keywords, any row whose *expression* evaluates to NULL is not included when *offset* rows are counted.

If you specify IGNORE NULLS and all of the *expression* values for the rows in the window partition are NULL, the LAG or LEAD function returns the *default* value for each row. The function returns the NULL value if no *default* argument is specified.

## Example: LEAD and LAG functions

In the following query, the LAG function and the LEAD function each defines an OLAP window that partitions employees by department and lists their salary. The LAG function shows how much more compensation each employee receives, compared to the employee in the same department with the next lower salary value. The LEAD function shows how much less each employee receives, compared to the employee in the same department with the next higher salary value.

```
SELECT name, salary, LAG(salary)
      OVER (PARTITION BY dept ORDER BY salary),
      LEAD(salary, 1, 0)
      OVER (PARTITION BY dept ORDER BY salary)
FROM employee;
```

| name  | salary | (lag)  | (lead) |
|-------|--------|--------|--------|
| John  | 35,000 |        | 38,400 |
| Jack  | 38,400 | 35,000 | 41,200 |
| Julie | 41,200 | 38,400 | 45,600 |
| Manny | 45,600 | 41,200 | 47,300 |
| Nancy | 47,300 | 45,600 | 49,500 |
| Pat   | 49,500 | 47,300 | 51,300 |
| Ray   | 51,300 | 49,500 | 0      |

The first row with name John has a NULL value for the LAG function because no default value is specified. The last row with name Ray has a 0 value for the LEAD function because 0 is specified as the default value of the third argument in the LEAD function.

## RANK function

The RANK function is an OLAP ranking function that calculates a ranking value for each row in an OLAP window. The return value is an ordinal number, which is based on the required ORDER BY expression in the OVER clause.

### Syntax

RANK function

**RANK** ( )

OVER clause for ranking functions <sup>640</sup>

### Usage

The rank of a row is defined as 1 plus the number of rows whose rankings precede that of the row. If two or more rows have the same value, these rows get the same rank as well. Results can have a gap in the sequence of consecutive ranked values. For example, if two rows are ranked 1, the next ranking is 3. The DENSE\_RANK function uses a different rule for ranking rows that include non-unique values.

The RANK function takes no argument, but the empty parentheses must be specified. If the OVER clause specifies the optional window PARTITION clause, the rankings are calculated within the subset of rows that each partition defines.

### Example

#### Example: RANK function

The following query ranks sales people by the amount of their sales. The ranks are not consecutive because ties in sales amounts are both assigned the same rank value, and the next rank value is skipped.

```
SELECT emp_num, sales,
       RANK() OVER (ORDER BY sales) AS rank
FROM sales;
```

| emp_num | sales | rank |
|---------|-------|------|
| 101     | 2,000 | 1    |
| 102     | 2,400 | 2    |
| 103     | 2,400 | 2    |
| 104     | 2,500 | 4    |
| 105     | 2,500 | 4    |
| 106     | 2,650 | 6    |

640. See [OVER clause for OLAP window expressions on page 1405](#)

## DENSE\_RANK function

The DENSE\_RANK function is an OLAP ranking function that calculates a ranking value for each row in an OLAP window. The return value is an ordinal number, which is based on the required ORDER BY expression in the OVER clause.

### Syntax

DENSE\_RANK function

**DENSE\_RANK DENSERANK**

( )

OVER clause for Ranking functions <sup>641</sup>

### Usage

The rank of a row is defined as 1 plus the number rankings that precede the ranking of the row. If two or more rows have the same value, these rows get the same rank. However, in contrast to the RANK function, if two or more rows tie, there is no gap in the sequence of ranked values. For example, if two rows are ranked 1, the next ranking is still 2.

This function takes no argument, but the empty parentheses must be specified. If the OVER clause specifies the optional window PARTITION clause, the DENSE\_RANK rankings are calculated within the subset of rows that each window partition defines.

### Example

#### Example: DENSE\_RANK function

The following query ranks sales people by the amount of their sales. Ranks are consecutive even if multiple sales amounts have the same rank.

```
SELECT emp_num, sales,
       DENSE_RANK() OVER (ORDER BY sales) AS dense_rank,
FROM sales;
```

| emp_num | sales | dense_rank |
|---------|-------|------------|
| 101     | 2,000 | 1          |
| 102     | 2,400 | 2          |
| 103     | 2,400 | 2          |
| 104     | 2,500 | 3          |
| 105     | 2,500 | 3          |
| 106     | 2,650 | 4          |

## PERCENT\_RANK function

The PERCENT\_RANK function is an OLAP ranking function that calculates a ranking value for each row in an OLAP window, normalized to a range from 0 to 1.

Each PERCENT\_RANK value is computed as the row's RANK minus 1, divided by the number of rows in the partition minus 1. Values closer to 1 generally represent higher rankings and values closer to 0 generally represent lower rankings.

641. See [OVER clause for OLAP window expressions on page 1405](#)

**Syntax**

PERCENT\_RANK function

**PERCENT\_RANK** ( ) OVER clause for Ranking functions<sup>642</sup>**Usage**

This function takes no argument, but the empty parentheses must be specified. If the optional window PARTITION clause is also specified, the rankings are calculated within the subset of rows that each partition defines. If there is a single row in the partition, its PERCENT\_RANK value is 0.

**Example****Example: PERCENT\_RANK function**

The following query ranks sales people by the amount of their sales.

```
SELECT emp_num, sales,
       PERCENT_RANK() OVER (ORDER BY sales) AS per_rank
FROM sales;
```

| emp_num | sales | per_rank |
|---------|-------|----------|
| 101     | 2,000 | 0        |
| 102     | 2,400 | 0.2      |
| 103     | 2,400 | 0.2      |
| 104     | 2,500 | 0.6      |
| 105     | 2,500 | 0.6      |
| 106     | 2,650 | 1.0      |

**CUME\_DIST function**

The CUME\_DIST function is an OLAP ranking function that calculates a cumulative distribution as a percentile ranking for each row. The rank is expressed as a decimal fraction that ranges from 0 to 1.

**Syntax**

CUME\_DIST function

**CUME\_DIST** ( ) OVER clause for Ranking functions<sup>643</sup>**Usage**

The CUME\_DIST function calculates the number of rows that are ranked lower than or equal to the current row, including the current row, which is divided by the total number of rows in the partition. Values closer to 1 represent higher rankings and values closer to 0 represent lower rankings.

This function takes no argument, but the empty parentheses must be specified. If the optional window PARTITION clause is also specified, the rankings are calculated within the subset of rows that each partition defines. If there is a single row in the partition, its CUME\_DIST value is 1.

642. See [OVER clause for OLAP window expressions on page 1405](#)

643. See [OVER clause for OLAP window expressions on page 1405](#)

**Example****Example: CUME\_DIST function**

The following query shows the cumulative distribution of the amount of sales per sales person.

```
SELECT emp_num, sales,
       CUME_DIST() OVER (ORDER BY sales) AS cume_dist
FROM sales;
```

| emp_num | sales | cume_dist   |
|---------|-------|-------------|
| 101     | 2,000 | 0.166666667 |
| 102     | 2,400 | 0.500000000 |
| 103     | 2,400 | 0.500000000 |
| 104     | 2,500 | 0.833333333 |
| 105     | 2,500 | 0.833333333 |
| 106     | 2,650 | 1.000000000 |

**NTILE function**

The NTILE function is an OLAP ranking function that classifies the rows in each partition into N ranked categories, called tiles, where each category includes an approximately equal number of rows.

**Syntax**

NTILE function

**NTILE**

(*unsigned*)

OVER clause for Ranking functions<sup>644</sup>

| Element         | Description  | Restrictions   | Syntax          |
|-----------------|--|----------------|-----------------|
| <i>unsigned</i> | Unsigned integer that specifies how many categories, or tiles, to rank | Cannot be zero | Literal integer |

**Usage**

The number of ranked categories, or tiles, is set by the unsigned integer argument to the function, and on the ORDER BY expression in the OVER clause.

For example, the following ranking function expression returns percentile rankings from 1 to 100 for the values in the **dollars** column for all the rows in the query result set:

```
NTILE(100) OVER(ORDER BY dollars)
```

When the argument is 4, the returned values sort the rows in each partition that the OVER clause defines into four quartiles. When a set of values is not divisible by the specified integer argument, the NTILE function puts leftover rows in the lower-ranked tiles.

644. See [OVER clause for OLAP window expressions on page 1405](#)

**Example****Example: NTILE function**

The following query ranks employees in departments by employee salary, and calculates the tile number of 1 through 5 for each department.

```
SELECT name, salary,
       NTILE(5) OVER (PARTITION BY dept ORDER BY salary)
FROM employee;
  name      salary      (ntile)
  ---      -
  John      35,000         1
  Jack      38,400         1
  Julie     41,200         2
  Manny     45,600         2
  Nancy     47,300         3
  Pat       49,500         4
  Ray       51,300         5
```

The salaries are ordered from lowest to highest because the default ordering direction for the ORDER BY clause is ascending. If you include the DESC keyword in the ORDER BY clause, the salaries are ordered from highest to lowest.

**OLAP aggregation function expressions**

OLAP aggregation function expressions can return aggregate information about rows in the partitioned results of a query.

OLAP aggregation function expressions are OLAP window expressions that you can include in the Projection list of a SELECT statement, or the ORDER BY clause of a SELECT statement.

**Syntax**

OLAP Aggregation function expressions

Aggregation functions OVER clause for Aggregation functions

OLAP Aggregation functions

FIRST\_VALUE function<sup>646</sup>

LAST\_VALUE function<sup>647</sup>

RATIO\_TO\_REPORT function<sup>648</sup>

OLAP Window Aggregate functions<sup>649</sup>

OVER clause for Aggregation functions

**OVER**<sup>645</sup>( Window PARTITION clause<sup>645</sup>

Window ORDER clause<sup>645</sup> Window Frame clause<sup>645</sup>

)

645. See [OVER clause for OLAP window expressions on page 1405](#)

646. See [FIRST\\_VALUE function on page 1397](#)

647. See [LAST\\_VALUE function on page 1398](#)

648. See [RATIO\\_TO\\_REPORT function on page 1399](#)

649. See [OLAP window aggregate functions on page 1400](#)

## Usage

You can apply the OLAP aggregation functions to subsets of the rows in an OLAP window partition by specifying a window frame.

---

### Related information

[Selecting Aggregate Function Expressions on page 784](#)

## FIRST\_VALUE function

The FIRST\_VALUE window aggregation function returns the value of a specified expression for the first row in each OLAP window partition.

### Syntax

FIRST\_VALUE function

**FIRST\_VALUE**

(*expression*)

**RESPECT NULLS IGNORE NULLS**

(*expression*

**RESPECT NULLS IGNORE NULLS**

)

OVER clause for aggregation functions<sup>650</sup>

| Element           | Description                                | Restrictions  | Syntax  |
|-------------------|--|---|---|
| <i>expression</i> | Column name, alias, or constant expression | If <i>expression</i> references a column, the column must also be in the select list of the Projection clause | <a href="#">Column Expressions on page 1219</a> |

## Usage

The return data type of the FIRST\_VALUE function is the data type of the specified expression. The result can be NULL. If IGNORE NULLS is specified, all rows where the expression value for the row evaluates to a NULL value are not considered in the calculation. If IGNORE NULLS is specified and all values in the OLAP window are NULL, the FIRST\_VALUE function returns the NULL value.

The RESPECT NULLS or IGNORE NULLS option can be specified either within the parentheses immediately following the expression, or outside the parentheses, but only one such specification is allowed.

## Example

650. See [OVER clause for OLAP window expressions on page 1405](#)

**Example: FIRST\_VALUE function**

The following statement returns stock prices by day and the differences in the stock prices from the first value, 18.25, in the window partition.

```
SELECT price, price - FIRST_VALUE(price)
      OVER (PARTITION BY year ORDER BY tradingday)
      AS diff_price
FROM stock_price
WHERE tradingday between '2012-11-01' and '2012-11-07';
```

| price | diff_price |
|-------|------------|
| 18.25 | 0          |
| 18.37 | 0.12       |
| 19.03 | 0.78       |
| 18.59 | 0.34       |
| 18.21 | -0.04      |

**LAST\_VALUE function**

The LAST\_VALUE window aggregation function returns the value of a specified expression for the last row in each OLAP window partition.

**Syntax**

LAST\_VALUE function

**LAST\_VALUE**

(*expression*)

**RESPECT NULLS IGNORE NULLS**

(*expression*)

**RESPECT NULLS IGNORE NULLS**

)

OVER clause for aggregation functions<sup>651</sup>

| Element           | Description                                | Restrictions  | Syntax  |
|-------------------|--|---|---|
| <i>expression</i> | Column name, alias, or constant expression | If <i>expression</i> references a column, the column must also be in the select list of the Projection clause | <a href="#">Column Expressions on page 1219</a> |

**Usage**

The return data type of the LAST\_VALUE function is the data type of the specified expression. The result can be NULL. If IGNORE NULLS is specified, all rows where the expression value for the row evaluates to a NULL value are not considered in the calculation. If IGNORE NULLS is specified and all values in the OLAP window are NULL, the LAST\_VALUE function returns the NULL value.

651. See [OVER clause for OLAP window expressions on page 1405](#)

The RESPECT NULLS or IGNORE NULLS option can be specified either within the parentheses immediately following the expression, or outside the parentheses, but only one such specification is allowed.

## RATIO\_TO\_REPORT function

The RATIO\_TO\_REPORT function calculates the fractional ratio of each row to the rest of the rows in the window partition, based on the numeric argument to the function.

### Syntax

RATIO\_TO\_REPORT function

**RATIO\_TO\_REPORT RATIO\_TO\_REPORT**

(*expression*)

OVER clause for aggregation functions <sup>652</sup>

| Element           | Description                                | Restrictions   | Syntax  |
|-------------------|--|--|---|
| <i>expression</i> | Column name, alias, or constant expression | The <i>expression</i> must evaluate to a numeric data type. DATE, DATETIME, and INTERVAL columns are not valid. If <i>expression</i> references a column, the column must also be in the select list of the Projection clause. | <a href="#">Column Expressions on page 1219</a> |

### Usage

This function calculates the ratio of values for a specified numeric column in a row versus the sum of values from all rows in each partition in an OLAP window frame. The name RATIO\_TO\_REPORT is a keyword synonym for RATIO\_TO\_REPORT.

As with all OLAP window aggregation functions, the Window PARTITION, Window ORDER, and Window Frame clauses are optional. The ratios can be applied either to partitioned rows or to the complete query result set. If a window Frame clause is also specified, then the calculated ratio applies to all rows from the current window frame.

The required *expression* argument must specify a column of a numeric data type, or else be a constant expression that evaluates to a numeric data type. If *expression* is not a numeric data type, the function fails with Error Message -25862.

If the sum of *expression* values for all the rows in the current window partition is zero, this function returns the NULL value for each row in that partition.

If another OLAP aggregation function, such as SUM or MAX, has an empty OVER clause, or if the OVER clause contains only a single window PARTITION specification, the result of the OLAP function is the same for every row in the partition. This is not the case, however, for RATIO\_TO\_REPORT, because different rows in the same window partition are assigned different ratios, totaling 1 (approximately) for each partition. To convert ratios to percentages, multiply the function expression by 100, as in the following example.

652. See [OVER clause for OLAP window expressions on page 1405](#)

**Example: RATIO\_TO\_REPORT function**

The following example calculates the decimal fraction of each city's sales, based on all rows that the query returns, as a single report that shows the sales totals for each city, in descending order.

```
SELECT city, SUM(dollars) AS SALES,
       RATIO_TO_REPORT(SUM(dollars)) OVER() *100 AS RATIO_DOLLARS
FROM sales, store, period
WHERE sales.store_id = store.store_id
      AND sales.period_id = period.period_id
GROUP BY city
ORDER BY sales DESC;
```

| CITY         | SALES     | RATIO_DOLLARS |
|--------------|-----------|---------------|
| San Jose     | 896931.15 | 12.58         |
| Atlanta      | 514830.00 | 7.22          |
| Miami        | 507022.35 | 7.11          |
| Los Angeles  | 503493.10 | 7.06          |
| Phoenix      | 437863.00 | 6.14          |
| New Orleans  | 429637.75 | 6.03          |
| Cupertino    | 424215.00 | 5.95          |
| Boston       | 421205.75 | 5.91          |
| Houston      | 417261.00 | 5.85          |
| New York     | 397102.50 | 5.57          |
| Los Gatos    | 394086.50 | 5.53          |
| Philadelphia | 392377.75 | 5.50          |
| Milwaukee    | 389378.25 | 5.46          |
| Detroit      | 305859.75 | 4.29          |
| Chicago      | 294982.75 | 4.14          |
| Hartford     | 236772.75 | 3.32          |
| Minneapolis  | 165330.75 | 2.32          |

In the example above, the *expression* argument to RATIO\_TO\_REPORT is the numeric aggregate function expression `SUM(dollars)`. The last row of the output indicates that the **sales** value for the **city** Minneapolis is approximately 2.32% of the total sales that the query reports.

**OLAP window aggregate functions**

Several functions that return aggregate results, such as sums and averages, from the results of a query can also be used as OLAP functions from the context of an OLAP window.

**Syntax**

Window aggregate functions

**AVG COUNT MAX MIN RANGE STDEV SUM VARIANCE**

(

**DISTINCT UNIQUE**

*table alias view synonym*

.

*column\_expr*)

OVER clause for aggregation functions<sup>653</sup>

653. See [OVER clause for OLAP window expressions on page 1405](#)

| Element  | Description  | Restrictions   | Syntax                                  |
|--|--|--|---|
| <i>column_expression</i>   | Column expression argument to the aggregate function       | See the headings for individual functions below                                  | <a href="#">Identifier on page 1456</a> |
| <i>alias</i> ,<br><i>synonym</i> ,<br><i>table</i> , <i>view</i> | Synonym, table, view, or alias that contains <i>column</i> | <i>Synonym</i> and the <i>table</i> or <i>view</i> to which it points must exist | <a href="#">Identifier on page 1456</a> |

## Usage

These aggregate functions do not require an OLAP window to calculate aggregate values from a query result set. They behave like OLAP window aggregation functions, however, in calling contexts where the OVER clause in the function expression defines one or more window partitions, or includes the window ORDER clause and the window Frame clause.

**Important:** When the DISTINCT or UNIQUE keyword is part of the window aggregate function specification, the OVER clause of the window aggregate expression cannot include the Window ORDER clause or the Window Frame clause.

The following aggregate functions can return information about the rows in OLAP window partitions.

### AVG function

The AVG function returns the average of all values in the specified column or expression in a window partition of the query results, for the rows in each partition that is defined in the OVER clause. If the OVER clause includes the Window Frame clause, AVG returns a value for each set of rows in a window frame.

You can apply the AVG function only to columns of number data types. If you use the DISTINCT (or UNIQUE) keyword, the average (meaning the mean) is calculated from only the distinct values in the specified column or expression, and the OVER clause cannot include a Window ORDER or Window Frame clause.

NULL values are ignored unless every value in the column or expression is NULL. If every value is NULL, the AVG function returns a NULL for that column or expression.

You cannot use the AVG function with a nonnumeric column or expression.

### COUNT function

The COUNT function returns the cardinality of non-NULL values in the specified column or expression in a window partition of the query results, for each partition that is defined in the OVER clause. If the OVER clause includes the Window Frame clause, COUNT returns a value for each set of rows in a window frame.

If you use the DISTINCT (or UNIQUE) keyword, the cardinality of rows in the partition is calculated from only the distinct values in the specified column or expression, and the OVER clause cannot include a Window ORDER or Window Frame clause.

NULL values are ignored unless every value in the column or expression is NULL. If every value is NULL, the COUNT function returns a NULL for that column or expression.

**MAX function**

The MAX function returns the largest value in the column or expression in a window partition of the query results, for the rows in each partition that is defined in the OLAP window OVER clause.

Specifying the DISTINCT or UNIQUE keyword has no effect on the results, but (as with the other built-in aggregate functions) no Window ORDER or Window Frame clause is allowed.

If the OVER clause includes the Window Frame clause, MAX returns a value for each set of rows in a window frame.

When a column expression is specified as argument to COUNT, NULL values are ignored unless every value in the specified column expression is NULL. If every value is NULL, MAX returns a NULL value for that column or expression. When COUNT(\*) is specified, NULL values are counted the same as other values.

**MIN function**

The MIN function returns the lowest value in the column or expression in a window partition of the query results, for each partition that the OLAP window OVER clause defines. If the OVER clause includes the Window Frame clause, the MIN function returns a value for each set of rows.

Specifying the DISTINCT or UNIQUE keyword has no effect on the results, but (as with the other built-in aggregate functions) no Window ORDER or window Frame clause is allowed.

If the OVER clause includes the Window Frame clause, MIN returns a value for each set of rows in a window frame.

NULL values are ignored unless every value in the specified column expression is NULL. If every value is NULL, MIN returns a NULL value for that column expression.

**RANGE function**

The RANGE function returns the range of values in the column or expression in a window partition of the query results, for each partition that the OLAP window OVER clause defines. If the OVER clause includes the Window Frame clause, RANGE returns a value for each set of rows in a window frame.

The RANGE function calculates the difference between the maximum and the minimum values, as follows:

```
range(expr) = max(expr) - min(expr)
```

You can apply the RANGE function only to numeric column expressions. The following query finds the range of ages for a population:

```
SELECT RANGE(age) OVER () FROM u_pop;
```

Because DATE values are stored internally as integers, you can use the RANGE function on DATE column. With a DATE column, the return value is the number of days between the earliest and latest dates in the column expression.

NULL values are ignored unless every value in the column expression is NULL. If every column expression value is NULL, the RANGE function returns a NULL for that column expression.

**STDEV function**

The STDEV function returns the standard deviation of a column or expression, using the following formula:

```
SQRT((SUM(Xi2) - (SUM(Xi)2)/N)/(N - 1))
```

In this formula,  $X_i$  is each column expression value in the window partition or frame that the OVER clause specifies, and N is the total number of non-NULL values in the column expression.

If the OVER clause includes the Window Frame clause, the STDEV function returns a value for each set of rows in a window frame.

NULL values are ignored, unless every value in the specified column expression is NULL. If every column expression value is NULL, the STDEV function returns NULL for that column expression.

You can apply the STDEV function only to numeric column expressions. You cannot use this function on column expressions of type DATE.

## SUM function

The SUM function calculates and returns the sum of all the values of a column expression in a window partition of the query results, for the rows in each partition that is defined in the OLAP window OVER clause.

If you use the DISTINCT (or UNIQUE) keyword as the first item in the argument list, the sum is for only distinct values in the column or expression, and no Window ORDER or Window Frame clause is allowed.

NULL values are ignored, unless every value is NULL. If every value is NULL, the SUM function returns the NULL value for that column or expression.

You cannot use the SUM function with a nonnumeric column or expression.

## VARIANCE function

The VARIANCE function calculates and returns the mean squared error as an estimate of the population variance of the values in a specified numeric column or expression for the partitions of query results that are defined in the OVER clause that follows the OLAP window VARIANCE expression.

If the OVER clause includes the Window Frame clause, the VARIANCE function returns a value for each set of rows, using the following formula:

$$\frac{(\text{SUM}(X_i^2) - (\text{SUM}(X_i)^2)/N)}{N - 1}$$

In this formula,

- $X_i$  is each column value in the window partition or frame that the OVER clause specifies,
- and N is the total number of non-NULL values in the column (unless all values are NULL, in which case the variance is logically undefined, and the VARIANCE function returns NULL).

You can apply the VARIANCE function only to numeric columns.

## Example

### Example: AVG function with partitioning

In the following example, the AVG function is used in an OLAP window aggregation expression to return the rolling average **closeprice** column values during the year 2012 for two window partitions, based on **ABC** and on **XYZ** values in the **symbol** column as the partitioning keys.

```

SELECT symbol, tradingdate,
       AVG(closeprice) OVER (PARTITION BY symbol
                            ORDER BY tradingdate
                            ROWS BETWEEN 29 PRECEDING AND CURRENT ROW)
FROM   dailystockdata
WHERE  symbol IN ('ABC', 'XYZ')
      AND tradingdate BETWEEN '2012-01-01' AND '2012-12-31';

```

The window ORDER clause specifies the **tradingdate** column value as the sorting key, and the window Frame clause defines a rolling window that is based on the average of 30 consecutive **tradingdate** values, ending with the **tradingdate** of the current row.

### Example

#### Example: AVG function without partitioning

The following query returns the stock price ordered by day and the average of the prices of the current day, the day before, and the day after. The result set is not partitioned because the query does not include a PARTITION BY clause.

```

SELECT price,
       AVG(price) OVER (ORDER BY tradingday
                       ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING)
FROM   stock_price
WHERE  tradingday BETWEEN '2012-11-01' AND '2012-11-07';

```

| price | (avg) |
|-------|-------|
| 18.25 | 18.31 |
| 18.37 | 18.31 |
|       | 18.37 |
|       | 19.03 |
| 19.03 | 18.81 |
| 18.59 | 18.61 |
| 18.21 | 18.40 |

The first value in the **avg** column is the average of the first two values in the **price** column, because no preceding values exist for the first value of the **price** column.

The second value in the **avg** column is the average of the first two values in the **price** column, because the third row of the **price** column does not have a value.

The third value in the **avg** column is equal to the second value in the **price** column because the third and fourth rows in the **price** column do not have values.

### Example

#### Example: COUNT function

The following query returns the shipping date, the shipping charge, and the number of orders for each order by customer. The query results are partitioned by customer number and limited to customer numbers that are less than or equal to 110.

```

SELECT customer_num, ship_date, ship_charge,
       COUNT(*) OVER (PARTITION BY customer_num)
FROM   orders
WHERE  customer_num <= 110;

customer_num ship_date  ship_charge  (count(*))

```

|     |            |         |   |
|-----|------------|---------|---|
| 101 | 05/26/2008 | \$15.30 | 1 |
| 104 | 05/23/2008 | \$10.80 | 4 |
| 104 | 07/03/2008 | \$5.00  | 4 |
| 104 | 06/01/2008 | \$10.00 | 4 |
| 104 | 07/10/2008 | \$12.20 | 4 |
| 106 | 05/30/2008 | \$19.20 | 2 |
| 106 | 07/03/2008 | \$12.30 | 2 |
| 110 | 07/06/2008 | \$13.80 | 2 |
| 110 | 07/16/2008 | \$6.30  | 2 |

Customer 104 appears in the list four times. The value in the **count** column is always 4 for customer 104.

**PARTITION BY***, partition\_key*

Window ORDER clause

**ORDER BY***, sorting\_key***ASC****DESC****NULLS****FIRST LAST**

Window Frame clause

**RANGE ROWS****UNBOUNDED PRECEDING***offset***PRECEDING****CURRENT ROW****BETWEEN****UNBOUNDED PRECEDING***offset***PRECEDING***offset***FOLLOWING****CURRENT ROW****AND****UNBOUNDED FOLLOWING***offset***PRECEDING***offset***FOLLOWING****CURRENT ROW**

| Element       | Description  | Restrictions   | Syntax           |
|---------------|--|--|------------------|
| <i>offset</i> | Unsigned integer that represents the offset from the position of the current row | Cannot be negative. If zero, specifies the current row | Literal integer. |

| Element              | Description   | Restrictions   | Syntax  |
|----------------------|---|--|---|
| <i>partition_key</i> | Column name, alias, or constant expression by which to partition rows | Must be in the select list of the Projection clause  | <a href="#">Column Expressions on page 1219</a> |
| <i>sorting_key</i>   | Column name, alias, or constant expression by which to sort rows      | Same restrictions as for <i>partition_key</i> . For RANGE window frames, only a single sorting key is allowed, and the data type must be numeric, DATE, or DATETIME. | <a href="#">Column Expressions on page 1219</a> |

If the OVER clause is empty, you must still include the empty parentheses.

### Window PARTITION clause

An OLAP window partition is a subset of the rows that are returned by a query. Each partition is defined by one or more column expressions in the PARTITION BY specification of the OVER clause that defines the window. The database server applies the specified OLAP window function to all of the rows in each window partition. If no partitions are defined in the OVER clause, the window function is applied to every row in the result set of the query.

### Window ORDER clause

The database server sorts the rows in each window partition according to the sort key (or multiple sort keys) in the window ORDER clause. If you specify no ascending (ASC) or descending (DESC) order, ASC is the default. If no ORDER clause is specified, the order of the qualifying rows is the order in which the rows were retrieved.

### Window Frame clause

The window Frame clause can return subsets, called *aggregation groups*, of the rows in each window partition. A window frame is defined by a specific number of rows or by a range of values.

#### Row-based window frame

The ROWS keyword creates a row-based window frame that consists of a specific number of rows that precede or follow the current row, or both. The offset represents the number of rows to return. The following example returns seven rows that include the six rows that precede the current row:

```
AVG(price) OVER (ORDER BY year, day
                ROWS BETWEEN 6 PRECEDING AND CURRENT ROW)
```

In a row-based window frame clause, offsets are expressed as unsigned integers because the keyword FOLLOWING specifies a positive offset from the current rows, and the keyword PRECEDING specifies a negative offset from the current row. The keyword UNBOUNDED refers to all of the rows from the current row to the limit of the window partition. As the first term after the ROWS keyword in a window Frame specification, UNBOUNDED PRECEDING means that the starting boundary is the first row in the partition, and UNBOUNDED FOLLOWING means that the ending boundary is the last row in the partition.

### Value-based window frame

The RANGE keyword creates a value-based frame clause that consists of the current row plus the rows that meet the criteria that is set by the sorting key in the ORDER clause and fit into the specified offset. The offset represents the number of units of the data type of the sorting key. The sorting key must be a numeric, DATE, or DATETIME data type. For example, if the sorting key is a DATE data type, the offset represents a specific number of days. The following example returns the count of the number of rows that have a ship date within 2 days of the current row plus the current row:

```
COUNT(*) OVER (ORDER BY ship_date
              RANGE BETWEEN 2 PRECEDING AND 2 FOLLOWING)
```

Value-based window frames define rows within a window partition that contain a specified range of numeric values. The window ORDER clause of the OVER function defines the numeric, DATE, or DATETIME column to which the RANGE specification is applied, relative to the current row value for that column. Only a single sorting key is allowed in the ORDER clause of value-based window frames.

In both the row-based and value-based cases, the OLAP function is calculated on the contents of this window frame, rather than the fixed contents of the whole partition. The window frame does not need to contain the current row. For example, the following specification defines a window frame that contains only the row before the current row:

```
ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING
```

If you specify no window ORDER clause for a window aggregation function, then by default, the result set is not restricted, which is equivalent to the following window frame specification:

```
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
```

If you specify an ORDER clause but no window frame clause for a window aggregation function, then by default, all rows that precede the current row and the current row are returned, which is equivalent to the following window frame specification:

```
ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
```

### Example

#### Example: SUM function without a window frame

The following query returns the sales by quarter for one year and the cumulative sum of the sales by quarter.

```
SELECT sales, SUM(sales) OVER (ORDER BY quarter)
FROM sales WHERE year = 2013
sales      (sum)
120        120
135        255
127        382
153        535
```

The sum of the sales for the fourth quarter is equal to the sales in all four quarters.

Because the query does not include a window frame clause, the SUM function operates on the entire result set, as specified by the FROM clause.

### Example

**Example: Row-based window frame**

The following query returns players that are partitioned by teams and ordered by the number of points. Within each partition, the number of points for the player and the previous player are averaged:

```
SELECT team, player, points,
       AVG(points) OVER(PARTITION BY team ORDER BY points
                        ROWS 1 PRECEDING AND CURRENT ROW) AS olap_avg
FROM points;
```

| TEAM | PLAYER | POINTS | OLAP_AVG        |
|------|--------|--------|-----------------|
| A    | Singh  | 7      | 7.000000000000  |
| A    | Smith  | 14     | 10.500000000000 |
| B    | Osaka  | 8      | 8.000000000000  |
| B    | Ricci  | 12     | 10.000000000000 |
| B    | Baxter | 18     | 15.000000000000 |
| C    | Chun   | 13     | 13.000000000000 |
| D    | Kwan   | 9      | 9.000000000000  |
| D    | Tran   | 16     | 12.500000000000 |

**Example****Example: Range-based window frame**

The following query returns players that are partitioned by teams and ordered by age. Within each partition, the number of points for each player and any player who is up to 9 years older is averaged:

```
SELECT player, age, team, points,
       AVG(points) OVER(PARTITION BY team ORDER BY age
                        RANGE BETWEEN CURRENT ROW AND 9 FOLLOWING) AS olap_avg
FROM points_age;
```

| PLAYER | AGE | TEAM | POINTS | OLAP_AVG        |
|--------|-----|------|--------|-----------------|
| Singh  | 25  | A    | 7      | 10.500000000000 |
| Smith  | 26  | A    | 14     | 14.000000000000 |
| Baxter | 27  | B    | 18     | 13.000000000000 |
| Osaka  | 35  | B    | 8      | 10.000000000000 |
| Ricci  | 40  | B    | 12     | 12.000000000000 |
| Chun   | 21  | C    | 13     | 13.000000000000 |
| Kwan   | 22  | D    | 9      | 12.500000000000 |
| Tran   | 31  | D    | 16     | 16.000000000000 |

In partition A, the average for Singh includes the points for Smith, because Smith is one year older than Singh. The average for Smith does not include the points from Singh, because Singh is younger than Smith.

In partition B, the average for Baxter includes the points for Osaka, who is 8 years older than Baxter, but not for Ricci, who is 13 years older than Baxter.

In partition D, the average for Kwan includes the points for Tran, because Tran is 9 years older than Kwan.

**Example: Window frame without the current row**

The following query calculates the average number of points for the preceding two rows in the partition:

```
SELECT player, age, team, points,
       AVG(points) OVER(PARTITION BY team ORDER BY age
                        ROWS BETWEEN 2 PRECEDING AND 1 PRECEDING) AS olap_avg
```

```

FROM points_age;
PLAYER      AGE  TEAM  POINTS  OLAP_AVG
Singh       25  A     7        NULL
Smith       26  A     14       7.0000000000
Baxter      27  B     18        NULL
Osaka       35  B     8        18.0000000000
Ricci       40  B     12       13.0000000000
Chun        21  C     13        NULL
Kwan        22  D     9         NULL
Tran        31  D     16       9.0000000000

```

In partition B, the average for Ricci is based on the points totals for Baxter and Osaka:  $(18 + 8) / 2 = 13$ . When the current row has no preceding rows to use for the calculation, the result is NULL.

## INTERVAL Field Qualifier

The INTERVAL field qualifier specifies the precision, in time units, for an INTERVAL value. Use the INTERVAL Field Qualifier segment whenever you see a reference to an INTERVAL field qualifier in a syntax diagram.

### Syntax

INTERVAL Field Qualifier

**DAY** (*precision*)

**TO DAY TO HOUR TO MINUTE TO SECOND**

**TO FRACTION**

(*scale*)

**HOUR** (*precision*)

**TO HOUR TO MINUTE TO SECOND**

**TO FRACTION**

(*scale*)

**MINUTE** (*precision*)

**TO MINUTE TO SECOND**

**TO FRACTION**

(*scale*)

**SECOND** (*precision*)

**TO SECOND**

**TO FRACTION**

**FRACTION**

**TO FRACTION**

(*scale*)

**YEAR** (*precision*)

**TO YEAR TO MONTH**

**MONTH** (*precision*) **TO MONTH**

| Element          | Description   | Restrictions                     | Syntax                                      |
|------------------|---|----------------------------------|---|
| <i>scale</i>     | Integer number of digits in FRACTION field. Default is 3.   | Must be in the range from 1 to 5 | <a href="#">Literal Number on page 1419</a> |
| <i>precision</i> | Integer number of digits in the largest time unit that the INTERVAL includes. For YEAR, the default is 4. For all other time units except FRACTION, the default is 2. | Must be in the range from 1 to 9 | <a href="#">Literal Number on page 1419</a> |

## Usage

This segment specifies the precision and scale of an INTERVAL data type.

A keyword specifying the *largest* time unit must be the first keyword, and a keyword specifying the *smallest* time unit must follow the TO keyword. These can be the same keyword. This segment resembles the syntax of a [DATETIME Field Qualifier on page 1191](#), but with these exceptions:

- If the largest time unit keyword is YEAR or MONTH, the smallest time unit keyword cannot specify a time unit smaller than MONTH.
- You can specify up to 9-digit *precision* after the first time unit, unless FRACTION is the first time unit (in which case no *precision* is valid after the first FRACTION keyword, but you can specify up to 5 digits of *scale* after the second FRACTION keyword).

Because *year* and *month* are not fixed-length units of time, the database server treats INTERVAL data types that include the YEAR or MONTH keywords in their qualifiers as incompatible with INTERVAL data types whose qualifiers are time units smaller than MONTH. The database server supports no implicit casts between these two categories of INTERVAL data types.

The next two examples show YEAR TO MONTH qualifiers of INTERVAL data types. The first example can hold an interval of up to 999 years and 11 months, because it gives 3 as the precision of the YEAR field. The second example uses the default precision on the YEAR field, so it can hold an interval of up to 9,999 years and 11 months.

```
YEAR (3) TO MONTH
```

```
YEAR TO MONTH
```

When you want a value to specify only one kind of time unit, the first and last qualifiers are the same. For example, an interval of whole years is qualified as YEAR TO YEAR or YEAR (5) TO YEAR, for an interval of up to 99,999 years.

The following examples show several forms of INTERVAL field qualifiers:

```
YEAR(5) TO MONTH
```

```
DAY (5) TO FRACTION(2)
```

```
DAY TO DAY
```

```
FRACTION TO FRACTION (4)
```

## Example

For information about how to specify INTERVAL field qualifiers and how to use INTERVAL data in arithmetic and relational operations, see the related reference, INTERVAL data type.

## Literal Collection

Use the Literal Collection segment to specify values for a collection data type. For the syntax of expressions that return values of individual elements within a collection, see [Collection Constructors on page 1248](#).

### Syntax

Literal Collection

#### SET MULTISSET LIST

{Literal Data}

Literal Data

,

Element Literal Value<sup>654</sup>

Nested Quotation Marks<sup>655</sup>

Literal Collection

Nested Quotation Marks<sup>655</sup>

### Usage

You can specify literal collection values for SET, MULTISSET, or LIST data types.

To specify a single literal-collection value, specify the collection type and the literal values. The following SQL statement inserts four integer values into a column called **set\_col** that was declared as `SET(INT NOT NULL)`:

```
INSERT INTO table1 (set_col) VALUES (SET{6, 9, 9, 4});
```

Specify an empty collection with an empty pair of braces ( `{}` ) symbols. This example inserts an empty list into a column **list\_col** that was declared as `LIST(INT NOT NULL)`:

```
INSERT INTO table2 (list_col) VALUES ('LIST{}');
```

A pair of single ( `'` ) or double ( `"` ) quotation marks can delimit the collection. Double quotation marks are not valid, however, in databases where delimited identifiers are enabled, except to delimit SQL identifiers.

If you are passing a literal collection as an argument to an SPL routine, make sure that there is a blank space between the parentheses that surround the arguments and quotation marks that indicate the beginning and end of the literal collection.

654. See [Element Literal Value on page 1413](#)

655. See [Nested Quotation Marks on page 1413](#)

**Related reference**[Literal Row on page 1421](#)

## Element Literal Value

The diagram for [Literal Collection on page 1412](#) refers to this section. Elements of a collection can be literal values for the following data types.

| For a Collection of Type  | Literal Value Syntax  |
|---|---|
| BOOLEAN   | <code>Ⓡ</code> or <code>Ⓢ</code> , representing TRUE or FALSE as a quoted string  |
| CHAR, VARCHAR, NCHAR, NVARCHAR, CHARACTER VARYING, LVARCHAR, DATE | <a href="#">Quoted String on page 1424</a>  |
| DATETIME  | <a href="#">Literal DATETIME on page 1414</a>   |
| DECIMAL, MONEY, FLOAT, INTEGER, INT8, SMALLFLOAT, SMALLINT        | <a href="#">Literal Number on page 1419</a>   |
| INTERVAL  | <a href="#">Literal INTERVAL on page 1418</a>   |
| Opaque data types   | <a href="#">Quoted String on page 1424</a> . The string literal must be recognized by the input support function for the associated opaque type.                    |
| Row Type  | <a href="#">Literal Row on page 1421</a> . When the collection element type is a named ROW type, you do not need to cast the inserted values to the named ROW type. |

**Important:** You cannot specify the simple-large-object data types (BYTE and TEXT) as the element type for a collection.

Quoted strings must be specified with a different type of quotation mark than the quotation marks that encompass the collection, so that the database server can parse the quoted strings. Thus, if you use double ( " ) quotation marks to specify the collection, use single ( ' ) quotation marks to specify individual, quoted-string elements. (In databases where delimited identifiers are enabled, however, double quotation marks are not valid, except to delimit SQL identifiers.)

## Nested Quotation Marks

The diagram for [Literal Collection on page 1412](#) refers to this section.

A *nested collection* is a collection that is the element type for another collection.

Whenever you nest collection literals, use nested quotation marks. In these cases, you must follow the rule for nesting quotation marks. Otherwise, the database server cannot correctly parse the strings.

The general rule is that you must double the number of quotation marks for each new level of nesting. For example, if you use double ( " ) quotation marks for the first level, you must use two double quotation marks for the second level, four double quotation marks for the third level, eight for the fourth level, sixteen for the fifth level, and so on.

Likewise, if you use single ( ' ) quotation marks for the first level, you must use two single quotation marks for the second level and four single quotation marks for the third level. There is no limit to the number of levels you can nest, as long as you follow this rule.

The following examples illustrate the case for two levels of nested collection literals, using double ( " ) quotation marks. Here table **tab5** is a single-column table whose only column, **set\_col**, is a nested collection type.

The following statement creates the **tab5** table:

```
CREATE TABLE tab5 (set_col SET(SET(INT NOT NULL) NOT NULL));
```

The following statement inserts values into the table **tab5**:

```
INSERT INTO tab5 VALUES ( "SET{"SET{34, 56, 23, 33}"}) );
```

For each literal value, the opening quotation mark and the closing quotation mark must match. Thus, if you open a literal with two double quotation marks, you must close that literal with two double quotation marks ( " "a literal value" ).

To specify nested quotation marks within an SQL statement in Informix® ESQL/C programs, use the C escape character for every double quotation mark inside a string that is delimited by single quotation marks. Otherwise, the Informix® ESQL/C preprocessor cannot correctly interpret the literal collection value. For example, the preceding INSERT statement on the **tab5** table would appear in the Informix® ESQL/C program as follows:

```
EXEC SQL insert into tab5
values ('set{"set{34, 56, 23, 33}"'});
```

For more information, see the chapter on complex data types in the *Informix® ESQL/C Programmer's Manual*.

If the collection is a nested collection, you must include the collection-constructor syntax for each level of collection type. Suppose you define the following column:

```
nest_col SET(MULTISET (INT NOT NULL) NOT NULL);
```

The following statement inserts three elements into the **nest\_col** column:

```
INSERT INTO tabx (nest_col)
VALUES ("SET{'MULTISET{1, 2, 3}'"});
```

## Literal DATETIME

The Literal DATETIME segment specifies a DATETIME value

Use this segment when you see a reference to a literal DATETIME in a syntax diagram.

**Syntax**

Literal DATETIME

**DATETIME**(Numeric Date and Time)DATETIME Field Qualifier<sup>656</sup>

Numeric Date and Time

*yyyy**-mo**-dd**spacehh**:mi**:ss**.ffff**mo**-dd**spacehh**:mi**:ss**.ffff**dd**spacehh**:mi**:ss**.ffff**hh**:mi**:ss**.ffff**mi**:ss**.ffff**ss**.ffff**ffff*

| Element     | Description                               | Restrictions                  | Syntax                                      |
|-------------|---|-------------------------------|---|
| <i>dd</i>   | Day of month, expressed in digits         | 1 <i>dd</i> 28, 29, 30, or 31 | <a href="#">Literal Number on page 1419</a> |
| <i>ffff</i> | Fraction of a second, expressed in digits | 0 <i>ffff</i> 99999           | <a href="#">Literal Number on page 1419</a> |
| <i>hh</i>   | Hour of day, expressed in digits          | 0 <i>hh</i> 23                | <a href="#">Literal Number on page 1419</a> |
| <i>mi</i>   | Minute of hour, expressed in digits       | 0 <i>mi</i> 59                | <a href="#">Literal Number on page 1419</a> |

656. See [DATETIME Field Qualifier on page 1191](#)

| Element      | Description                        | Restrictions              | Syntax                                      |
|--------------|------------------------------------|---------------------------|---|
| <i>mo</i>    | Month of year, expressed in digits | 1 <i>mo</i> 12            | <a href="#">Literal Number on page 1419</a> |
| <i>space</i> | Blank space (ASCII 32)             | Exactly 1 blank character | Literal blank space                         |
| <i>ss</i>    | Second of minute, in digits        | 0 <i>ss</i> 59            | <a href="#">Literal Number on page 1419</a> |
| <i>yyyy</i>  | Year, expressed in digits          | No more than 4 digits     | <a href="#">Literal Number on page 1419</a> |

## Usage

You must specify both a numeric date and a DATETIME field qualifier for this date in the Literal DATETIME segment. The DATETIME field qualifier must correspond to the numeric date you specify. For example, if you specify a numeric date that includes a year as the largest unit and a minute as the smallest unit, you must also specify YEAR TO MINUTE as the DATETIME field qualifier.

If you specify two digits for the year, the database server uses the setting of the **DBCENTURY** environment variable to expand the abbreviated year value to four digits. If the **DBCENTURY** is not set, the first two digits of the current year are used to expand the abbreviated year value.

The following examples show literal DATETIME values:

```
DATETIME (07-3-6) YEAR TO DAY
DATETIME (09:55:30.825) HOUR TO FRACTION
DATETIME (07-5) YEAR TO MONTH
```

The following example shows a literal DATETIME value used with the EXTEND function:

```
EXTEND (DATETIME (2007-8-1) YEAR TO DAY, YEAR TO MINUTE)
- INTERVAL (720) MINUTE (3) TO MINUTE
```

## Precedence of DATE and DATETIME format specifications

The Informix® environment variables whose settings can specify the display and data entry formats for values of DATE data types have the following order of precedence, if different settings are in conflict, or if no format is specified:

1. **DBDATE**
2. **GL\_DATE**
3. Information defined in the client locale (if **CLIENT\_LOCALE** is set)
4. Default date format is `%m/%d/%iY` (if **DBDATE** and **GL\_DATE** are not set, and no locale is specified)

Informix® environment variables can specify the display and data entry formats for values of DATETIME data types. Their explicit or default settings have the following descending order of precedence (from highest to lowest), if different settings are in conflict, or if no format is specified:

1. **DBDATE** and **DBTIME**
2. **GL\_DATETIME**
3. Information defined in the client locale (if **CLIENT\_LOCALE** is set)
4. Default DATETIME format is `%iY-%m-%d %H:%M:%S` (if **CLIENT\_LOCALE**, **DBTIME** and **GL\_DATETIME** are not set).

If **GL\_DATETIME** is set to a nondefault value, you must also set the **USE\_DTENV** environment variable to `1` before you can process localized **DATETIME** values correctly in the following contexts:

- dbexport utility
- dbimport utility
- LOAD statement of DB-Access
- UNLOAD statement of DB-Access
- DML operations on objects defined by the CREATE EXTERNAL TABLE statement.

For details of how you can set these environment variables to define formats for chronological data values, see the *Informix® GLS User's Guide* and *Informix® Guide to SQL: Reference*.

---

[INTERVAL Field Qualifier on page 1410](#)

## Casting Numeric Date and Time Strings to DATE Data Types

The database server provides a built-in cast to convert DATETIME values to DATE values, as in the following SPL program fragment:

```
DEFINE my_date DATE;
DEFINE my_dt DATETIME YEAR TO SECOND;
. . .
LET my_date = CURRENT;
```

Here the DATETIME value that CURRENT returns is implicitly cast to DATE. You can also cast DATETIME to DATE explicitly:

```
LET my_date = CURRENT::DATE;
```

Both of these LET statements assign the *year*, *month*, and *day* information from the DATETIME value to the local SPL variable **my\_date** of type DATE.

Similarly, you can cast explicitly a string that has the format of the Numeric Date and Time segment, as defined in the [Literal DATETIME on page 1414](#) syntax diagram, to a DATETIME data type, as in the following example:

```
LET my_dt =
('2008-02-22 05:58:44.000')::DATETIME YEAR TO SECOND;
```

There is neither an implicit nor an explicit built-in cast, however, for directly converting a character string that has the Numeric Date and Time format to a DATE value. Both of the following statements, for example, fail with error -1218:

```
LET my_date = ('2008-02-22 05:58:44.000');
LET my_date = ('2008-02-22 05:58:44.000')::DATE;
```

To convert a character string that specifies a valid numeric date and time value to a DATE data type, you must first cast the string to DATETIME, and then cast the resulting DATETIME value to DATE, as in this example:

```
LET my_date =
('2008-02-22 05:58:44.000')::DATETIME YEAR TO SECOND::DATE;
```

A direct string-to-DATE cast can succeed only if the string specifies a valid DATE value.

## Literal INTERVAL

The Literal INTERVAL segment specifies a literal INTERVAL value. Use this whenever you see a reference to a literal INTERVAL in a syntax diagram.

### Syntax

| <i>ss</i>    | Number of seconds      | If not first, 0 <i>ss</i> 59          | <a href="#">Literal Number on page 1419</a> |
| <i>yyyy</i>  | Number of years        | -10**10 < <i>yyyy</i> < 10**10        | <a href="#">Literal Number on page 1419</a> |

## Usage

Unlike DATETIME literals, INTERVAL literals can include the unary plus (+) or unary minus (-) sign. If you specify no sign, the default is plus.

The precision of the first time unit can be specified by the INTERVAL qualifier. Except for FRACTION, which can have no more than 5 digits of precision, the first time unit can have up to 9 digits of precision, if you specified a nondefault precision in the declaration of the INTERVAL column or variable.

The following examples show literal INTERVAL values:

```
INTERVAL (3-6) YEAR TO MONTH
INTERVAL (09:55:30.825) HOUR TO FRACTION
INTERVAL (40 5) DAY TO HOUR
INTERVAL (299995.2567) SECOND(6) TO FRACTION(4)
```

Only the last of these examples has nondefault precision. For the syntax of declaring the precision of INTERVAL data types and the default values for each time unit, refer to [INTERVAL Field Qualifier on page 1410](#).

## Literal Number

A *literal number* is the base-10 representation of a real number as an integer, as a fixed-point decimal number, or in exponential notation. Use the Literal Number segment whenever you see a reference to a literal number in a syntax diagram.

**Syntax**

Literal Number

+

-

*digit*

.

.

*digit*

.

*digit***e E**

-

+

*digit*

| Element      | Description                  | Restrictions           | Syntax                             |
|--------------|------------------------------|------------------------|------------------------------------|
| <i>digit</i> | Integer in range 0 through 9 | Must be an ASCII digit | Literal entered from the keyboard. |

**Usage**

You cannot include comma ( , ) or blank (ASCII 32) character. The unary plus ( + ) or minus ( - ) sign can precede a literal number, mantissa, or exponent.

You cannot include non-ASCII digits in literal numbers.

**Integer Literals**

An integer has no fractional part and cannot include a decimal point. Built-in data types of SQL that can be exactly represented as literal integers include BIGINT, BIGSERIAL, DECIMAL(*p*, 0), INT, INT8, SERIAL, SERIAL8, and SMALLINT.

If you use the representation of a number in a base other than 10 (such as a binary, octal, or hexadecimal) in any context where a literal integer is valid, the database server will attempt to interpret the value as a base-10 literal integer. For most data values, the result will be incorrect.

The following examples show some valid literal integers:

```
10          -27          +25567
```

Thousands separators (such as comma symbols) are not valid in literal integers, nor in any other literal number.

**Fixed-Point Decimal Literals**

Fixed-point decimal literals can exactly represent DECIMAL(*p*,*s*) and MONEY values. These can include a decimal point:

```
-123.456    00123456    +123456.0
```

The digits to the right of the decimal point in these examples are the fractional portions of the numbers.

## Floating-Point Decimal Literals

Floating-point literals can exactly represent `FLOAT`, `SMALLFLOAT`, and `DECIMAL(p)` values, using a decimal point or exponential notation, or both. They can approximately represent real numbers in exponential notation. The next examples show floating point numbers:

```
-123.45E6      1.23456E2      123456.0E-3
```

The `E` in the previous examples is the symbol for exponential notation. The digit that follows `E` is the value of the exponent. For example, the number `3E5` (or `3E+5`) means 3 multiplied by 10 to the fifth power, and the number `3E-5` means 3 multiplied by the reciprocal of 10 to the fifth power.

## Literal Numbers and the MONEY Data Type

When you use a literal number as a `MONEY` value, do not include a currency symbol or include commas. The `DBMONEY` environment variable or the locale file can format how `MONEY` values are displayed in output.

## Literal Row

The Literal Row segment specifies the syntax for literal values of named and unnamed `ROW` data types.

For expressions that evaluate to field values within a `ROW` data type, see [ROW constructors on page 1247](#).

**Syntax**

Literal Row

```
' ROW(
, Field Literal Value
)'
```

```
ROW(
, Field Literal Value
)
```

Field Literal Value

Quoted String<sup>658</sup>Literal Number<sup>659</sup>**USER**Literal DATETIME<sup>660</sup>Literal INTERVAL<sup>661</sup>Literal Collection<sup>662</sup>*literal\_opaque\_type* 'literal\_BOOLEAN'

ROW(Literal Row)

| Element                    | Description                                    | Restrictions   | Syntax   |
|----------------------------|--|--|--|
| <i>literal_opaque_type</i> | Literal representation for an opaque data type | Must be a literal that is recognized by the input support function for the associated opaque data type | Defined by the developer of the opaque data type |
| <i>literal_BOOLEAN</i>     | Literal representation of a BOOLEAN value      | Must be either 'E' (= TRUE) or 'F' (= FALSE) specified as a quoted string                              | <a href="#">Quoted String on page 1424</a>       |

**Usage**

You can specify literal values for named ROW and unnamed ROW data types. A ROW constructor introduces a literal ROW value, which can optionally be enclosed between quotation marks.

The format of the value for each field of the ROW type must be compatible with the data type of the corresponding field.

**Important:** You cannot specify simple-large-object data types (BYTE or TEXT) as the field type for a row.

Fields of a row can be literal values for the data types in the following table.

658. See [Quoted String on page 1424](#)

659. See [Literal Number on page 1419](#)

660. See [Literal DATETIME on page 1414](#)

661. See [Literal INTERVAL on page 1418](#)

662. See [Literal Collection on page 1412](#)

| For a Field of Type  | Literal Value Syntax  |

[Literal Collection on page 1412](#)

## Literals of an Unnamed Row Type

To specify a literal value for an unnamed ROW type, introduce the literal row with the ROW constructor; you must enclose the values between parentheses. For example, suppose that you define the **rectangles** table as follows:

```
CREATE TABLE rectangles
(
  area FLOAT,
  rect ROW(x INTEGER, y INTEGER, length FLOAT, width FLOAT),
)
```

The following INSERT statement inserts values into the **rect** column of the **rectangles** table:

```
INSERT INTO rectangles (rect)
VALUES ("ROW(7, 3, 6.0, 2.0)")
```

## Literals of a Named Row Type

To specify a literal value for a named ROW type, introduce the literal row with the ROW type constructor and enclose the literal values for each field in parentheses. In addition, you can cast the row literal to the appropriate named ROW type to ensure that the row value is generated as a named ROW type. The following statements create the named ROW type **address\_t** and the **employee** table:

```
CREATE ROW TYPE address_t
(
street CHAR(20),
city CHAR(15),
state CHAR(2),
zipcode CHAR(9)
);

CREATE TABLE employee
(
name CHAR(30),
address address_t
);
```

The following INSERT statement inserts values into the **address** column of the **employee** table:

```
INSERT INTO employee (address)
VALUES (
"ROW('103 Baker St', 'Tracy','CA', 94060)::address_t)
```

## Literals for Nested Rows

If the literal value is for a nested row, specify the ROW type constructor for each row level. If you include quotation marks as delimiters, they should enclose the outermost row. For example, suppose that you create the **emp\_tab** table:

```
CREATE TABLE emp_tab
(
emp_name CHAR(10),
emp_info ROW( stats ROW(x INT, y INT, z FLOAT))
);
```

The following INSERT statement adds a row to the **emp\_tab** table:

```
INSERT INTO emp_tab VALUES ('joe boyd', "ROW(ROW(8,1,12.0))" );
```

Similarly, if the row-string literal contains a nested collection, only the outermost literal row can be enclosed between quotation marks. Do not put quotation marks around an inner, nested collection type.

## Quoted String

A quoted string is a string literal between quotation marks. Use this segment whenever you see a reference to a quoted string in a syntax diagram.

### Syntax

Quoted String

```
'
character "
'
663.
character ""
"
```

| Element          | Description                           | Restrictions  | Syntax                          |
|------------------|---------------------------------------|---|---------------------------------|
| <i>character</i> | Code set element within quoted string | Cannot enclose between double quotation marks if the <b>DELIMITED</b> environment variable is set | Literal value from the keyboard |

### Usage

Use quoted strings to specify string literals in data-manipulation statements and other SQL statements. For example, you can use a quoted string in an INSERT statement to insert a value into a column of a character data type.

## Restrictions on Specifying Characters in Quoted Strings

You must observe the following restrictions on *character* in quoted strings:

- If you are using the ASCII code set, you can specify any printable ASCII character, including a single ( ' ) quotation mark or double ( " ) quotation mark. For restrictions that apply to using quotation marks in quoted strings, see [Using Quotation Marks in Strings on page 1427](#).
- In some locales, you can specify non-ASCII characters, including multibyte characters, that the locale supports. See the discussion of quoted strings in the *Informix® GLS User's Guide*.
- If you enable newline characters for quoted strings, you can embed newline characters in quoted strings. For further information, see [Newline Characters in Quoted Strings on page 1426](#).
- You can enter DATETIME and INTERVAL data values as quoted strings. For the restrictions that apply to entering DATETIME and INTERVAL data in quoted-string format, see [DATETIME and INTERVAL Values as Strings on page 1427](#).
- Quoted strings that are used with the LIKE or MATCHES keyword in a search condition can include wildcard characters that have a special meaning in the search condition. For further information, see [LIKE and MATCHES in a Condition on page 1428](#).
- When you insert a value that is a quoted string, you must observe a number of restrictions. For further information, see [Inserting Values as Quoted Strings on page 1428](#).

663. Informix® extension

## The DELIMIDENT Environment Variable

If the **DELIMIDENT** environment variable is set on the database server, you cannot use double quotation marks ( " ) to delimit literal strings. If **DELIMIDENT** is set, the database server interprets strings enclosed in double quotation marks as SQL identifiers, not as literal strings. If **DELIMIDENT** is not set, a string between double quotation marks is interpreted as a literal string, not an identifier. For further information, see [Using Quotation Marks in Strings on page 1427](#), and the description of **DELIMIDENT** in *Informix® Guide to SQL: Reference*.

**DELIMIDENT** is also supported on client systems, where it can be set to `y`, to `n`, or to no setting.

- `y` specifies that client applications must use single quotation mark ( ' ) symbols to delimit literal strings, and must use double quotation mark ( " ) symbols only around delimited SQL identifiers. Delimited identifiers can support a larger character set than is valid for undelimited identifiers. Letters within delimited strings or delimited identifiers are case-sensitive.
- `n` specifies that client applications can use double quotation mark ( " ) or single quotation mark ( ' ) symbols to delimit character strings, but not to delimit SQL identifiers. If the database server encounters a string delimited by double or single quotation mark symbols in a context where an SQL identifier is required, it issues an error. An owner name, however, that qualifies an SQL identifier can be delimited by single quotation mark ( ' ) symbols. You must use a pair of the same quotation mark symbols to delimit a character string.
- Specifying **DELIMIDENT** with no value on the client system requires client applications to use the **DELIMIDENT** setting that is the default for their application programming interface (API).

Client APIs of Informix® use the following default **DELIMIDENT** settings:

- For OLE DB and .NET, the default **DELIMIDENT** setting is `y`
- For ESQL/C, JDBC, and ODBC, the default **DELIMIDENT** setting is `n`
- APIs that have ESQL/C as an underlying layer, the DataBlade® API (LIBDMI), and the C++ API, behave as ESQL/C, and use `n` as the default if no value for **DELIMIDENT** is specified on the client system.

Even if **DELIMIDENT** is set, you can use single quotation mark ( ' ) symbols to delimit *authorization identifiers* as the owner name component of a database object name, as in the following example:

```
RENAME COLUMN 'Owner'.table2.collum3 TO column3;
```

The general rule, however, is that when **DELIMIDENT** is set, the SQL parser interprets strings delimited by single quotation marks as string literals, and interprets character strings delimited by double quotation marks ( " ) as SQL identifiers.

## Newline Characters in Quoted Strings

By default, the string constant must be written on a single line. That is, you cannot use embedded newline characters in a quoted string. You can, however, override this default behavior in one of two ways:

- To enable newline characters in quoted strings in all sessions, set the `ALLOW_NEWLINE` parameter to 1 in the `ONCONFIG` file.
- To enable newline characters in quoted strings for the current session, execute the built-in function **`IFX_ALLOW_NEWLINE`**.

This enables newline characters in quoted strings for the current session:

```
EXECUTE PROCEDURE IFX_ALLOW_NEWLINE('T');
```

If newline characters in quoted strings are not enabled for a session, the following statement is invalid and returns an error:

```
SELECT 'The quick brown fox
      jumped over the old gray fence'
FROM customer
WHERE customer_num = 101;
```

If you enable newline characters in quoted strings for the session, however, the statement in the preceding example is valid and executes successfully.

For more information on the **`IFX_ALLOW_NEWLINE`** function, see [IFX\\_ALLOW\\_NEWLINE Function on page 1361](#). For more information on the `ALLOW_NEWLINE` parameter in the `ONCONFIG` file, see your .

## Using Quotation Marks in Strings

The single quotation mark ( `'` ) has no special significance in string literals delimited by double quotation marks. Conversely, double quotation mark ( `"` ) has no special significance in strings delimited by single quotation marks. For example, these strings are valid:

```
"Nancy's puppy jumped the fence"
'Billy told his kitten, "No!" '
```

A string delimited by double quotation marks can include a double quotation mark character by preceding it with another double quotation mark, as the following string shows:

```
"Enter ""y"" to select this row"
```

When the **`DELIMIT`** environment variable is set, double quotation marks can only delimit SQL identifiers, not strings. For more information on delimited identifiers, see [Delimited Identifiers on page 1458](#).

## DATETIME and INTERVAL Values as Strings

You can enter `DATETIME` and `INTERVAL` data in the literal forms described in the [Literal DATETIME on page 1414](#) and [Literal INTERVAL on page 1418](#), or you can enter them as quoted strings.

Valid literals that are entered as character strings are converted automatically into `DATETIME` or `INTERVAL` values.

These statements enter `INTERVAL` and `DATETIME` values as quoted strings:

```
INSERT INTO cust_calls(call_dtime) VALUES ('2007-5-4 10:12:11');
INSERT INTO manufact(lead_time) VALUES ('14');
```

The format of the value in the quoted string must exactly match the format specified by the INTERVAL or DATETIME qualifiers of the column. For the first INSERT in the preceding example, the **call\_dtime** column must be defined with the qualifiers YEAR TO SECOND for the INSERT statement to be valid.

## LIKE and MATCHES in a Condition

Quoted strings with the LIKE or MATCHES keyword in a condition can include wildcard characters. For a complete description of how to use wildcard characters, see [Condition on page 1144](#).

## Inserting Values as Quoted Strings

In the default locale, if you are inserting a value that is a quoted string, you must adhere to the following restrictions:

- Enclose CHAR, VARCHAR, NCHAR, NVARCHAR, DATE, DATETIME, INTERVAL, and LVARCHAR values in quotation marks.
- Specify DATE values in the *mm/dd/yyyy* format (or in the format that the **DBDATE** or **GL\_DATE** environment variable specifies, if set).
- You cannot insert strings longer than 32 kilobytes.
- Numbers with decimal values must include a decimal separator. Comma ( , ) is not valid as a decimal separator in the default locale.
- MONEY values cannot include a dollar sign ( \$ ) or commas.
- You can enter NULL in a column only if it accepts null values.

## Numeric Operations on Character Columns

Avoid comparing number literals to character columns. It requires that all of the strings compared be converted to numbers, which takes much longer than comparing two strings.

For example, suppose that you wish to find all customers within the 356 telephone exchange code:

```
SELECT lname FROM customer WHERE phone [5,7] = '356';
```

Notice that the operand whose value is 356 is enclosed in quotes. The quotes indicate that the database server must handle the filter as a character string. By contrast, when the operand is not in quotes, the server treats each retrieved value as a number, and must implicitly cast each value retrieved from the table to a numeric data type.

The following example causes implicit data type conversion of the **phone** substrings:

```
SELECT lname FROM customer WHERE phone [5,7] = 356;
```

If the UPDATE STATISTICS MEDIUM or UPDATE STATISTICS HIGH statement has been run on this column, the query optimizer tries to determine the selectivity of the predicate by matching the constant in the query with a substring of values saved in the distribution bin. Requiring data type conversion of every row in a character column so that it can be compared to

a numeric filter needlessly increases the cost of the query that omits quotation mark delimiters around 356, compared to cost of the query in the first example.

Queries that compare character strings to numbers can fail with EM -1213 if the database server cannot convert the string. If you cannot avoid applying numeric filters to character values, only attempt such operations on character columns whose characters are restricted to digits in the range ASCII 0x30 through 0x39, and decimal point (ASCII 0x2e). This range is also known as *seminumeric*.

The database server does not use an index when DML statements compare a character column with a noncharacter value that is not equal in length to the character column.

## Relational Operator

A relational operator compares two expressions quantitatively. Use the Relational Operator segment whenever you see a reference to a relational operator in a syntax diagram.

### Syntax

Relational Operator

< <= >

= ==

>= <>

664<sub>1</sub>!=

### Usage

The relational operators of SQL have the following meanings.

#### Relational Operator

##### Meaning

<

Less than

<=

Less than or equal to

>

Greater than

= *or* ==

Equal to

>=

Greater than or equal to

664. Informix® extension

**<> or !=**

Not equal to

**Usage**

For number expressions, *greater than* means to the right on the real line.

For DATE and DATETIME expressions, *greater than* means later in time.

For INTERVAL expressions, *greater than* means a longer span of time.

For CHAR, VARCHAR, and LVARCHAR expressions, *greater than* means *after* in code-set order.

For NCHAR and NVARCHAR expressions, *greater than* means *after* in the localized collation order, if one exists; otherwise, *greater than* means *after* in code-set order.

Locale-based collation order, if one is defined for the locale, is used for NCHAR and NVARCHAR expressions. So for NCHAR and NVARCHAR expressions, *greater than* means *after* in the locale-based collation order. For more information on locale-based collation order and the NCHAR and NVARCHAR data types, see the *Informix® GLS User's Guide*.

For information on how relational operator expressions with NCHAR and NVARCHAR operands in databases that have the NLCASE INSENSITIVE property differ from their behavior in databases that are case sensitive, see the topic [NCHAR and NVARCHAR expressions in case-insensitive databases on page 1174](#).

---

**Using Operator Functions in Place of Relational Operators**

Each relational operator is bound to a particular operator function, as the table shows. The operator function accepts two values and returns a boolean value of true, false, or unknown.

**Relational Operator****Associated Operator Function**

&lt;

**lessthan( )**

&lt;=

**lessthanorequal( )**

&gt;

**greaterthan( )**

&gt;=

**greaterthanorequal( )****= or ==****equal( )**

**<> or !=**

### **notequal( )**

Connecting two expressions with a relational operator is equivalent to invoking the operator function on the expressions. For example, the next two statements both select orders with a shipping charge of \$18.00 or more.

The **>=** operator in the first statement implicitly invokes the **greaterthanorequal( )** operator function:

```
SELECT order_num FROM orders
  WHERE ship_charge >= 18.00;

SELECT order_num FROM orders
  WHERE greaterthanorequal(ship_charge, 18.00);
```

The database server provides the operator functions associated with the relational operators for all built-in data types. When you develop a user-defined data type, you must define the operator functions for that type for users to be able to use the relational operator on the type.

If you define **lessthan( )**, **greaterthan( )**, and the other operator functions for a user-defined type, then you should also define **compare( )**. Similarly, if you define **compare( )**, then you should also define **lessthan( )**, **greaterthan( )**, and the other operator functions. All of these functions must be defined in a consistent manner, to avoid the possibility of incorrect query results when UDT values are compared in the WHERE clause of a SELECT.

## Collating Order for U.S. English Data

If you are using the default locale (U.S. English), the database server uses the code-set order of the default code set when it compares the character expressions that precede and follow the relational operator.

On UNIX™, the default code set is the ISO8859-1 code set, which consists of the following sets of characters:

- The ASCII characters have code points in the range of 0 to 127.  
This range contains control characters, punctuation symbols, English-language characters, and numerals.
- The 8-bit characters have code points in the range 128 to 255.  
This range includes many non-English-language characters (such as é, , , and ñ) and symbols (such as £, ©, and ç).

In Windows™, the default code set is Microsoft™ 1252. This code set includes both the ASCII code set and a set of 8-bit characters.

This table lists the ASCII code set. The **Num** columns show ASCII code point numbers, and the **Char** columns display corresponding ASCII characters. In the default locale, ASCII characters are sorted according to their code-set order. Thus, lowercase letters follow uppercase letters, and both follow digits. In this table, ASCII 32 is the blank character, and the caret symbol (^) stands for the **CTRL** key. For example, ^X means **CONTROL-X**.

| Num | Char |
|-----|------|-----|------|-----|------|-----|------|-----|------|-----|------|-----|------|
| 0   | ^@   | 20  | ^T   | 40  | (    | 60  | <    | 80  | P    | 100 | d    | 120 | x    |

| Num | Char |
|-----|------|-----|------|-----|------|-----|------|-----|------|-----|------|-----|------|
| 1   | ^A   | 21  | ^U   | 41  | )    | 61  | =    | 81  | Q    | 101 | e    | 121 | y    |
| 2   | ^B   | 22  | ^V   | 42  | *    | 62  | >    | 82  | R    | 102 | f    | 122 | z    |
| 3   | ^C   | 23  | ^W   | 43  | +    | 63  | ?    | 83  | S    | 103 | g    | 123 | {    |
| 4   | ^D   | 24  | ^X   | 44  | ,    | 64  | @    | 84  | T    | 104 | h    | 124 |      |
| 5   | ^E   | 25  | ^Y   | 45  | -    | 65  | A    | 85  | U    | 105 | i    | 125 | }    |
| 6   | ^F   | 26  | ^Z   | 46  | .    | 66  | B    | 86  | V    | 106 | j    | 126 | ~    |
| 7   | ^G   | 27  | esc  | 47  | /    | 67  | C    | 87  | W    | 107 | k    | 127 | del  |
| 8   | ^H   | 28  | ^\   | 48  | 0    | 68  | D    | 88  | X    | 108 | l    |     |      |
| 9   | ^I   | 29  | ^]   | 49  | 1    | 69  | E    | 89  | Y    | 109 | m    |     |      |
| 10  | ^J   | 30  | ^^   | 50  | 2    | 70  | F    | 90  | Z    | 110 | n    |     |      |
| 11  | ^K   | 31  | ^_   | 51  | 3    | 71  | G    | 91  | [    | 111 | o    |     |      |
| 12  | ^L   | 32  |      | 52  | 4    | 72  | H    | 92  | \    | 112 | p    |     |      |
| 13  | ^M   | 33  | !    | 53  | 5    | 73  | I    | 93  | ]    | 113 | q    |     |      |
| 14  | ^N   | 34  | "    | 54  | 6    | 74  | J    | 94  | ^    | 114 | r    |     |      |
| 15  | ^O   | 35  | #    | 55  | 7    | 75  | K    | 95  | _    | 115 | s    |     |      |
| 16  | ^P   | 36  | \$   | 56  | 8    | 76  | L    | 96  | `    | 116 | t    |     |      |
| 17  | ^Q   | 37  | %    | 57  | 9    | 77  | M    | 97  | a    | 117 | u    |     |      |
| 18  | ^R   | 38  | &    | 58  | :    | 78  | N    | 98  | b    | 118 | v    |     |      |
| 19  | ^S   | 39  | '    | 59  | ;    | 79  | O    | 99  | c    | 119 | w    |     |      |

## Support for ASCII Characters in Nondefault Code Sets (GLS)

Most code sets for nondefault locales (called *nondefault code sets*) support the ASCII characters. In a nondefault locale, the database server uses ASCII code-set order for ASCII data in CHAR and VARCHAR expressions, if the code set supports these ASCII characters. If the current collation (as specified by **DB\_LOCALE** or by SET COLLATION) supports a localized collating order, however, that localized order is used when the database server sorts NCHAR or NVARCHAR values.

## Literal Numbers as Operands

You might obtain unexpected results if a literal number that you specify as an operand is not in a format that can exactly represent the data type of another value with which it is compared by a relational operator. Because of rounding errors, for

example, a relational operator like `=` or the `equals()` operator function generally cannot return `TRUE` if one operand returns a `FLOAT` value and the other an `INTEGER`. For information about which of the built-in data types store values that can be exactly represented as literal numbers, see the section [Literal Number on page 1419](#).

## Other syntax segments

These topics describe *syntax segments*, which are language elements, such as database object names or optimizer directives, that appear as a subdiagram reference in the syntax diagrams of some SQL or SPL statements.

Most segments that can occur in only one statement are described in [SQL statements on page 16](#) or [SPL statements on page 1081](#) within the description of the statement. For the sake of clarity, ease of use, and comprehensive treatment, however, most segments that can occur in various SQL or SPL statements, and that are not data types nor expressions, are discussed separately here.

The previous chapter described the syntax segments that specify data types and expressions. This chapter describes additional syntax segments that are neither data types, expressions, nor complete SQL statements or SPL statements. These segments are referenced in various syntax diagrams that appear in [SQL statements on page 16](#) and in other chapters of this document.

## Arguments

Use the Argument segment to pass a specific value as input to a routine. Use this segment wherever you see a reference to an *argument* in a syntax diagram.

### Syntax

Argument

*parameter*=

Subset of Expression <sup>665</sup>

### NULL

(*singleton\_select*)

| Element                 | Description                                | Restrictions   | Syntax                                       |
|-------------------------|--|--|--|
| <i>parameter</i>        | A parameter whose value you specify        | Must match a name that CREATE FUNCTION or CREATE PROCEDURE statement declared            | <a href="#">Identifier on page 1456</a>      |
| <i>singleton_select</i> | Embedded query that returns a single value | Must return exactly one value of a data type and length compatible with <i>parameter</i> | <a href="#">SELECT statement on page 768</a> |

665. See [Subset of Expressions Valid as an Argument on page 1435](#)

## Usage

The CREATE PROCEDURE or CREATE FUNCTION statement can define a parameter list for a UDR. If the parameter list is not empty, you must enter arguments when you invoke the UDR. An *argument* is a specific value whose data type is compatible with that of the corresponding UDR parameter.

When you execute a UDR, you can enter arguments in either of two ways:

- With a parameter name (in the form *parameter name = expression*), even if the arguments are not in the same order as the parameters
- By position, with no *parameter* name, where each *expression* is in the same order as the parameter to which the argument corresponds. (This is sometimes called *ordinal* format.)

You cannot mix these two ways of specifying arguments within a single invocation of a routine. If you specify a *parameter* name for one argument, for example, you must use parameter names for all the arguments.

In the following example, both statements are valid for a user-defined procedure that expects three character arguments, **t**, **d**, and **n**:

```
EXECUTE PROCEDURE add_col (t = 'customer', d = 'integer',  
    n = 'newint');  
  
EXECUTE PROCEDURE add_col ('customer', 'newint', 'integer') ;
```

## Comparing Arguments to the Parameter List

When you create or register a UDR with CREATE PROCEDURE or CREATE FUNCTION, you declare a *parameter list* with the names and data types of the parameters that the UDR expects. (Parameter names are optional for external routines written in the C or Java™ languages.) See [Routine Parameter List on page 1514](#) for details of declaring parameters.

User-defined routines can be *overloaded*, if different routines have the same identifier, but have different numbers of declared parameters. For more information about overloading, see [Routine Overloading and Routine Signatures on page 1454](#).

If you attempt to execute a UDR with more arguments than the UDR expects, you receive an error.

If you invoke a UDR with fewer arguments than the UDR expects, the omitted arguments are said to be *missing*. The database server initializes missing arguments to their corresponding default values. This initialization occurs before the first executable statement in the body of the UDR.

If missing arguments have no default values, Informix® issues an error.

Named parameters cannot be used to invoke UDRs that overload data types in their routine signatures. Named parameters are valid in resolving non-unique routine names only if the signatures have different numbers of parameters:

```
func( x::integer, y );    -- VALID if only these 2 routines
func( x::integer, y, z ); -- have the same 'func' identifier

func( x::integer, y );    -- NOT VALID if both routines have
func( x::float, y );      -- same identifier and 2 parameters
```

For both ordinal and named parameters, the routine with the fewest parameters is executed if two or more UDR signatures have multiple numbers of defaults:

```
func( x, y default 1 )
func( x, y default 1, z default 2 )
```

If two registered UDRs that are both called **func** have the signatures shown above, then the statement `EXECUTE func(100)` invokes **func(100,1)**.

You cannot supply a subset of default values using named parameters unless they are in the positional order of the routine signature. That is, you cannot skip a few arguments and rely on the database server to supply their default values.

For example, given the signature:

```
func( x, y default 1, z default 2 )
```

you can execute:

```
func( x=1, y=3 )
```

but you cannot execute:

```
func( x=1, z=3 )
```

## Subset of Expressions Valid as an Argument

The diagram for [Arguments on page 1433](#) refers to this section.

You can use any expression as an argument, except an aggregate function. If you use a subquery or function call as an argument, the subquery or function must return a single value of the appropriate data type and size. For the syntax and usage of SQL expressions, see [Expression on page 1193](#).

## Arguments to UDRs in Remote Databases

UDRs are valid in cross-database and in cross-server distributed operations in most contexts where a UDR is valid in the local database, but every participating database must have the same logging mode.

Excluding BIGSERIAL, BYTE, SERIAL, SERIAL8, and TEXT, the data types that are valid as arguments to cross-server UDRs include the built-in SQL data types that are not opaque, as listed in [Data Types in Distributed Queries on page 779](#), and these additional built-in opaque and DISTINCT data types:

- BOOLEAN
- LVARCHAR
- DISTINCT of built-in types that are not opaque
- DISTINCT of BOOLEAN
- DISTINCT of LVARCHAR
- DISTINCT of the DISTINCT types listed above.

These data types can be arguments to SPL, C, or Java™ language UDRs, if the UDRs are defined in all the participating databases. Any implicit or explicit casts defined over these data types must be duplicated across all the participating Informix® instances. The DISTINCT data types must have exactly the same data type hierarchy defined in all databases that participate in the distributed query.

The same data types are valid as arguments in calls to UDRs in other databases of the same Informix® instance, as well as arguments of the following additional types:

- BLOB
- CLOB
- UDTs that you cast explicitly to built-in types

All the UDRs, UDTs, DISTINCT data types, DISTINCT type hierarchies, casts, and cast functions must be registered in all of the participating databases. For more information on DISTINCT types in distributed operations, see [DISTINCT Types in Distributed Operations on page 1184](#).

## Collection-Derived Table

A *collection-derived table* is a virtual table in which the values in the rows of the table are equivalent to elements of a collection. Use this segment where you see a reference to Collection-Derived Table in a syntax diagram. This syntax is an extension to the ANSI/ISO standard for SQL.

**Syntax**

Collection-Derived Table

**TABLE**<sup>666</sup>

```
(
collection_expr)
AS alias
alias
(
, derived_column
)
667 668collection_var
668row_var
)
```

| Element                                   | Description   | Restrictions   | Syntax   |
|---|---|--|--|
| <i>alias</i>                              | Temporary name for a collection-derived table whose scope is a SELECT statement. The default is implementation dependent.       | If potentially ambiguous, you must precede <i>alias</i> with the AS keyword. See <a href="#">Aliases for Tables or Views on page 793</a> . | <a href="#">Identifier on page 1456</a>  |
| <i>collection_expr</i>                    | Any expression that evaluates to the elements of a single collection  | See <a href="#">Restrictions with the Collection-Expression Format on page 1439</a> .  | <a href="#">Expression on page 1193</a>  |
| <i>collection_var</i> ,<br><i>row_var</i> | Name of a typed or untyped collection variable, or Informix® ESQL/C <b>row</b> variable that holds the collection-derived table | Must have been declared in the Informix® ESQL/C program or (for <i>collection_var</i> ) in an SPL routine                                  | See the <i>Informix® ESQL/C Programmer's Manual</i> or <a href="#">DEFINE on page 1089</a> . |
| <i>derived_column</i>                     | Temporary name for a derived column in a table  | If the underlying collection is not of a ROW data type, you can specify only one derived-column name                                       | <a href="#">Identifier on page 1456</a>  |

**Usage**

A collection-derived table can appear where a *table* name is valid in the UPDATE statement, in the FROM clause of the SELECT or DELETE statement, or in the INTO clause of an INSERT statement.

Use the collection-derived-table segment to accomplish these tasks:

666. Informix® extension

667. Stored Procedure Language

668. ESQL/C

- Access the elements of a collection as you would the rows of a table.
- Specify a collection variable to access, instead of a table name.
- Specify an ESQL/C **row** variable to access, instead of a table name.

The **TABLE** keyword converts a collection into a virtual table. You can use the collection expression format to query a collection column, or you can use the **collection** variable or **row** variable format to manipulate the data in a collection column.

## Accessing a Collection Through a Virtual Table

When you use the collection expression format of the collection-derived table segment to access the elements of a collection, you can select elements of the collection directly through a virtual table. You can use this format in the **FROM** clause of a **SELECT** statement. The **FROM** clause can be in either a query or a subquery.

With this format you can use joins, aggregates, the **WHERE** clause, expressions, the **ORDER BY** clause, and other operations that are not available when you use the collection-variable format. This format reduces the need for multiple cursors and temporary tables.

Examples of possible collection expressions include column references, scalar subquery, dotted expression, functions, operators (through overloading), collection subqueries, literal collections, collection constructors, cast functions, and so on.

The following example uses a **SELECT** statement in the **FROM** clause whose result set defines a virtual table consisting of the fifty-first through seventieth qualifying rows, ordered by the **employee\_id** column value.

```
SELECT * FROM TABLE(MULTISET(SELECT SKIP 50 FIRST 20 * FROM employees
ORDER BY employee_id)) vt(x,y), tab2 WHERE tab2.id = vt.x;
```

The following example uses a join query to create a virtual table of no more than twenty rows (beginning with the 41st row), ordered by value in the **salary** column of the collection-derived table:

```

SELECT emp_id, emp_name, emp_salary
FROM TABLE(MULTISET(SELECT SKIP 40 LIMIT 20 id, name, salary
                    FROM e1, e2
                    WHERE e1.id = e2.id ORDER BY salary ))
AS etab(emp_id, emp_name, emp_salary);

```

## Table Expressions in the FROM Clause

Informix® supports ANSI/ISO standard syntax for table expressions in the FROM clause of SELECT queries and subqueries as a substitute for the Informix®-extension collection-derived table syntax. The keywords TABLE and MULTISET were required in version 10.00 and in earlier releases. These extensions to the ANSI/ISO standard for SQL are supported but no longer required for collection-derived table specifications in the FROM clause of SELECT statements.

The following two queries return the same result set, but only the second query complies with the ANSI/ISO standard:

```

SELECT * FROM TABLE(MULTISET(SELECT col1 FROM tab1 WHERE col1 = 100))
AS vtab(c1),
(SELECT col1 FROM tab1 WHERE col1 = 10) AS vtab1(vc1) ORDER BY c1;

SELECT * FROM (SELECT col1 FROM tab1 WHERE col1 = 100) AS vtab(c1),
(SELECT col1 FROM tab1 WHERE col1 = 10) AS vtab1(vc1)
ORDER BY c1;

```

The same SELECT statement can combine instances of both the Informix®-extension and ANSI/ISO syntax for derived tables:

```

SELECT * FROM (SELECT col1 FROM tab1 WHERE col1 = 100) AS vtab(c1),
TABLE(MULTISET(SELECT col1 FROM tab1 WHERE col1 = 10)) AS vtab1(vc1)
ORDER BY c1;

```

The subquery must be delimited by parentheses in both formats, but the outer set of parentheses ( ( ) ) that immediately follows the TABLE keyword and encloses the MULTISET collection subquery specification is an extension to the ANSI/ISO syntax. This ANSI/ISO syntax is valid only in the FROM clause of the SELECT statement. You cannot omit these keywords and parentheses from a collection subquery specification in any other context.

## Restrictions with the Collection-Expression Format

When you use the collection-expression format, certain restrictions apply:

- A collection-derived table is read-only.
  - It cannot be the target of INSERT, UPDATE, or DELETE statements.
    - To perform insert, update, and delete operations, you must use the collection-variable format.
  - It cannot be the underlying table of an updatable cursor or view.
- In the FROM clause of the SELECT statement, the CALL keyword of SPL cannot precede the TABLE keyword of a table expression.

- If the collection is a LIST data type, the resulting collection-derived table does not preserve the order of the elements in the LIST.
- The underlying collection expression cannot evaluate to NULL.
- The collection expression cannot contain a reference to a collection on a remote database server.
- The collection expression cannot contain column references to tables that appear in the same FROM clause. That is, the collection-derived table must be independent of other tables in the FROM clause.

For example, the following statement returns an error because the collection-derived table, `TABLE(parents.children)`, refers to the **parents** table, which is also referenced in the FROM clause:

```
SELECT COUNT(*)
  FROM parents, TABLE(parents.children) ctable
 WHERE parents.id = 1001;
```

To counter this restriction, you might write a query that contains a subquery in the Projection clause:

```
SELECT (SELECT COUNT(*)
  FROM TABLE(parents.children) ctable)
  FROM parents WHERE parents.id = 1001;
```

## Additional Restrictions That Apply to ESQ/C

In addition to the previously described restrictions, the following restrictions also apply when you use the collection-expression format with Informix® ESQ/C:

- You cannot specify an untyped COLLECTION as the host-variable data type.
- You cannot use the format `TABLE(?)`.

The data type of the underlying collection variable must be determined statically. To counter this restriction, you can explicitly cast the variable to a typed collection data type (SET, MULTISET, or LIST) that the database server recognizes. For example,

```
TABLE(CAST(? AS type))
```

- You cannot use the format `TABLE(:hostvar)`.

To counter this restriction, you must explicitly cast the variable to a typed collection data type (SET, MULTISET, or LIST) that the database server recognizes. For example,

```
TABLE(CAST(:hostvar AS type))
```

## Row Type of the Resulting Collection-Derived Table

If you do not specify a derived-column name, the behavior of the database server depends on the data types of the elements in the underlying collection.

Although a collection-derived table appears to contain columns of individual data types, these columns are, in fact, the fields of a ROW data type. The data type of the ROW type as well as the column name depend on several factors.

If the data type of the elements of the underlying collection expression is *type*, the database server determines the ROW type of the collection-derived table by the following rules:

- If *type* is a ROW data type, and no derived-column list is specified, then the ROW type of the collection-derived table is *type*.
- If *type* is a ROW data type and a derived column list is specified, then the ROW type of the collection-derived table is an unnamed ROW type whose column data types are the same as those of *type* and whose column names are taken from the derived column list.
- If *type* is not a ROW data type, the ROW type of the collection-derived table is an unnamed ROW type that contains one column of *type* and whose name is specified in the derived column list. If no name is specified, the database server assigns an implementation-dependent name to the column.

The extended examples that the following table shows illustrate these rules. The table uses the following schema for its examples:

```
CREATE ROW TYPE person (name CHAR(255), id INT);
CREATE TABLE parents
(
  name CHAR(255),
  id INT,
  children LIST (person NOT NULL)
);
CREATE TABLE parents2
(
  name CHAR(255),
  id INT,
  children_ids LIST (INT NOT NULL)
);
```

| ROW Type | Explicit Derived-Column List | Resulting ROW Type of the Collection-Derived Table  | Code Example   |
|----------|------------------------------|---|--|
| Yes      | No                           | <i>Type</i>   | <pre>SELECT (SELECT c_table.name FROM TABLE(parents.children) c_table WHERE c_table.id = 1002) FROM parents WHERE parents.id = 1001;</pre> <p>In this example, the ROW type of <b>c_table</b> is <b>parents</b>.</p>   |
| Yes      | Yes                          | Unnamed ROW type of which the column type is <i>Type</i> and the column name is the name in the derived-column list | <pre>SELECT (SELECT c_table.c_name FROM TABLE(parents.children) c_table(c._name, c_id) WHERE c_table.c_id = 1002) FROM parents WHERE parents.id = 1001;</pre> <p>In this example, the ROW type of <b>c_table</b> is ROW(<b>c_name</b> CHAR(255), <b>c_id</b> INT).</p> |
| No       | No                           | Unnamed ROW that contains one column of <i>Type</i> that is assigned an   | In the following example, if you do not specify <b>c_id</b> , the database server assigns a name to the derived column. In this case, the ROW type of <b>c_table</b> is ROW( <i>server_defined_name</i> INT).  |

| ROW Type | Explicit Derived-Column List | Resulting ROW Type of the Collection-Derived Table  | Code Example   |
|----------|------------------------------|---|--|
|          |                              | implementation-dependent name   |  |
| No       | Yes                          | Unnamed ROW type that contains one column of <i>Type</i> whose name is in the derived-column list | <pre>SELECT(SELECT c_table.c_id FROM TABLE(parents2.child_ids) c_table (c_id) WHERE c_table.c_id = 1002) FROM parents WHERE parents.id = 1001;</pre> <p>Here the ROW type of <b>c_table</b> is ROW(<b>c_id</b> INT).</p> |

The following program fragment creates a collection-derived table using an SPL function that returns a single value:

```
CREATE TABLE wanted(person_id int);
CREATE FUNCTION
  wanted_person_count (person_set SET(person NOT NULL))
RETURNS INT;
RETURN( SELECT COUNT (*)
  FROM TABLE (person_set) c_table, wanted
  WHERE c_table.id = wanted.person_id);
END FUNCTION;
```

The next program fragment shows the more general case of creating a collection-derived table using an SPL function that returns multiple values:

```
-- Table of categories and child categories,
-- allowing any number of levels of subcategories
CREATE TABLE CategoryChild (
  categoryId    INTEGER,
  childCategoryId SMALLINT
);

INSERT INTO CategoryChild VALUES (1, 2);
INSERT INTO CategoryChild VALUES (1, 3);
INSERT INTO CategoryChild VALUES (1, 4);
INSERT INTO CategoryChild VALUES (2, 5);
INSERT INTO CategoryChild VALUES (2, 6);
INSERT INTO CategoryChild VALUES (5, 7);
INSERT INTO CategoryChild VALUES (7, 8);
INSERT INTO CategoryChild VALUES (7, 9);
INSERT INTO CategoryChild VALUES (4, 10);

-- "R" == ROW type
CREATE ROW TYPE categoryLevelR (
  categoryId    INTEGER,
  level        SMALLINT );

-- DROP FUNCTION categoryDescendants (
--   INTEGER, SMALLINT );
CREATE FUNCTION categoryDescendants (
  pCategoryId INTEGER,
  pLevel      SMALLINT DEFAULT 0 )
RETURNS MULTISET (categoryLevelR NOT NULL)
```

```

-- "p" == Prefix for Parameter names
-- "l" == Prefix for Local variable names
DEFINE lCategoryId LIKE CategoryChild.categoryId;
DEFINE lRetSet MULTISET (categoryLevelR NOT NULL);
DEFINE lCatRow categoryLevelR;

-- TRACE ON;
-- Must initialize collection before inserting rows
LET lRetSet = 'MULTISET{ }' :: MULTISET (categoryLevelR NOT NULL);

FOREACH
SELECT childCategoryId INTO lCategoryId
  FROM CategoryChild WHERE categoryId = pCategoryId;
INSERT INTO TABLE (lRetSet)
  VALUES (ROW (lCategoryId, pLevel+1)::categoryLevelR);

-- INSERT INTO TABLE (lRetSet);
-- EXECUTE FUNCTION categoryDescendantsR ( lCategoryId,
-- pLevel+1 );
-- Need to iterate over results and insert into SET.
-- See the SQL Tutorial, pg. 10-52:
-- "Tip: You can only insert one value at a time
-- into a simple collection."
  FOREACH
    EXECUTE FUNCTION categoryDescendantsR ( lCategoryId, pLevel+1 )
      INTO lCatRow;
      INSERT INTO TABLE (lRetSet)
        VALUES (lCatRow);
  END FOREACH;
END FOREACH;

RETURN lRetSet;
END FUNCTION
;
-- "R" == recursive
-- DROP FUNCTION categoryDescendantsR (INTEGER, SMALLINT);
CREATE FUNCTION categoryDescendantsR (
  pCategoryId INTEGER,
  pLevel      SMALLINT DEFAULT 0
)
RETURNS categoryLevelR;
DEFINE lCategoryId LIKE CategoryChild.categoryId;
DEFINE lCatRow    categoryLevelR;

FOREACH
  SELECT  childCategoryId
  INTO    lCategoryId
  FROM    CategoryChild
  WHERE   categoryId = pCategoryId
  RETURN ROW (lCategoryId, pLevel+1)::categoryLevelR WITH RESUME;

  FOREACH
    EXECUTE FUNCTION categoryDescendantsR ( lCategoryId, pLevel+1 )
      INTO    lCatRow
      RETURN  lCatRow WITH RESUME;
  END FOREACH;
END FOREACH;
END FUNCTION;

```

```
-- Test the functions:
SELECT lev, col
FROM TABLE ((
    categoryDescendants (1, 0)
)) AS CD (col, lev);
```

## Accessing a Collection Through a Collection Variable

When you use the collection-variable format of the collection-derived table segment, you use a host or program variable to access and manipulate the elements of a collection. This format allows you to modify the contents of a variable as you would a table in the database, and then update the actual table with the contents of the **collection** variable.

You can use the collection-variable format (the TABLE keyword preceding a **collection** variable) in place of the name of a table, synonym, or view in the following SQL statements (or in the FOREACH statement of SPL):

- The FROM clause of the SELECT statement to access an element of the **collection** variable
- The INTO clause of the INSERT statement to add a new element to the **collection** variable
- The DELETE statement to remove an element from the **collection** variable
- The UPDATE statement to modify an existing element in the **collection** variable
- The DECLARE statement to declare a Select or Insert cursor to access multiple elements of the Informix® ESQL/C **collection** host variable
- The FETCH statement to retrieve a single element from a **collection** host variable that is associated with a Select cursor
- The PUT statement to retrieve a single element from a **collection** host variable that is associated with an Insert cursor
- The FOREACH statement to declare a cursor to access multiple elements of an SPL collection variable and to retrieve a single element from this **collection** variable

## Using a Collection Variable to Manipulate Collection Elements

### About this task

When you use data manipulation statements (SELECT, INSERT, UPDATE, or DELETE) of Informix® in conjunction with a **collection** variable, you can modify one or more elements in a collection.

### To modify elements in a collection

1. Create a **collection** variable in your SPL routine or Informix® ESQL/C program.  
For information on how to declare a **collection** variable in Informix® ESQL/C, see the *Informix® ESQL/C Programmer's Manual*. For information on how to define a **COLLECTION** variable in SPL, see [DEFINE on page 1089](#).
2. In Informix® ESQL/C, allocate memory for the collection; see [ALLOCATE COLLECTION statement on page 16](#).
3. Optionally, use a SELECT statement to select a **COLLECTION** column into the **collection** variable.

If the variable is an untyped COLLECTION variable, you must perform a SELECT from the COLLECTION column before you use the variable in the collection-derived table segment. The SELECT statement allows the database server to obtain the collection data type.

4. Use the appropriate data manipulation statement with the collection-derived table segment to add, delete, or update elements in the collection variable.

To insert more than one element or to update or delete a *specific* element of a collection, you must use a cursor for the collection variable.

- For more information on how to use an update cursor with ESQL/C, see [DECLARE statement on page 467](#).
- For more information on how to use an update cursor with SPL, see [FOREACH on page 1107](#).

5. After the collection variable contains the correct elements, use an INSERT or UPDATE statement on the table or view that holds the actual collection column to save the changes that the collection variable holds.

- With UPDATE, specify the collection variable in the SET clause.
- With INSERT, specify the collection variable in the VALUES clause.

## Results

The collection variable stores the elements of the collection. It has no intrinsic connection, however, with a database column. Once the collection variable contains the correct elements, you must then save the variable into the actual collection column of the table with either an INSERT or an UPDATE statement.

## Example of Deleting from a Collection in ESQL/C

Suppose that the **set\_col** column of a row in the **table1** table is defined as a SET and for one row contains the values {1, 8, 4, 5, 2}. The following Informix® ESQL/C code fragment uses an update cursor and a DELETE statement with a WHERE CURRENT OF clause to delete the element whose value is 4:

```
EXEC SQL BEGIN DECLARE SECTION;
    client collection set(smallint not null) a_set;
    int an_int;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL allocate collection :a_set;
EXEC SQL select set_col into :a_set from table1 where int_col = 6;
EXEC SQL declare set_curs cursor for
    select * from table(:a_set) for update;

EXEC SQL open set_curs;
while (i < coll_size)
{
    EXEC SQL fetch set_curs into :an_int;
    if (an_int = 4)
    {
        EXEC SQL delete from table(:a_set) where current of set_curs;
        break;
    }
    i++;
}
```

```
EXEC SQL update table1 set set_col = :a_set
  where int_col = 6;
EXEC SQL deallocate collection :a_set;
EXEC SQL close set_curs;
EXEC SQL free set_curs;
```

After the DELETE statement executes, this collection variable contains the elements {1, 8, 5, 2}. The UPDATE statement at the end of this code fragment saves the modified collection into the **set\_col** column. Without this UPDATE statement, element 4 of the collection column is not deleted.

## Example of Deleting from a Collection

Suppose that the **set\_col** column of a row in the **table1** table is defined as a SET and one row contains the values {1, 8, 4, 5, 2}. The following SPL code fragment uses a FOREACH loop and a DELETE statement with a WHERE CURRENT OF clause to delete the element whose value is 4:

```
CREATE_PROCEDURE test6()

  DEFINE a SMALLINT;
  DEFINE b SET(SMALLINT NOT NULL);
  SELECT set_col INTO b FROM table1
    WHERE id = 6;
    -- Select the set in one row from the table
    -- into a collection variable
  FOREACH cursor1 FOR
    SELECT * INTO a FROM TABLE(b);
    -- Select each element one at a time from
    -- the collection derived table b into a
    IF a = 4 THEN
      DELETE FROM TABLE(b)
        WHERE CURRENT OF cursor1;
        -- Delete the element if it has the value 4
      EXIT FOREACH;
    END IF;
  END FOREACH;

  UPDATE table1 SET set_col = b
    WHERE id = 6;
    -- Update the base table with the new collection

END PROCEDURE;
```

This SPL routine declares two SET variables, **a** and **b**, each to hold a set of SMALLINT values. The first SELECT statement copies a SET column from one row of **table1** into variable **b**. The routine then declares a cursor called **cursor1** that copies one element at a time from **b** into SET variable **a**. When the cursor is positioned on the element whose value is 4, the DELETE statement removes that element from SET variable **b**. Finally, the UPDATE statement replaces the row of **table1** with the new collection that is stored in variable **b**.

For information on how to use collection variables in an SPL routine, see the *Informix® Guide to SQL: Tutorial*.

## Example of Updating a Collection

Suppose that the **set\_col** column of a table called **table1** is defined as a SET and that it contains the values {1, 8, 4, 5, 2}. The following Informix® ESQL/C program changes the element whose value is 4 to a value of 10:

```
main
{
  EXEC SQL BEGIN DECLARE SECTION;
    int a;
    collection b;
  EXEC SQL END DECLARE SECTION;

  EXEC SQL allocate collection :b;
  EXEC SQL select set_col into :b from table1
    where int_col = 6;

  EXEC SQL declare set_curs cursor for
    select * from table(:b) for update;
  EXEC SQL open set_curs;
  while (SQLCODE != SQLNOTFOUND)
  {
    EXEC SQL fetch set_curs into :a;
    if (a = 4)
    {
      EXEC SQL update table(:b)(x)
        set x = 10 where current of set_curs;
      break;
    }
  }
  EXEC SQL update table1 set set_col = :b
    where int_col = 6;
  EXEC SQL deallocate collection :b;
  EXEC SQL close set_curs;
  EXEC SQL free set_curs;
}
```

After you execute this Informix® ESQL/C program, the **set\_col** column in **table1** contains the values {1, 8, 10, 5, 2}.

This Informix® ESQL/C program defines two **collection** variables, **a** and **b**, and selects a SET from **table1** into **b**. The WHERE clause ensures that only one row is returned. Then the program defines a Collection cursor, which selects elements one at a time from **b** into **a**. When the program locates the element with the value 4, the first UPDATE statement changes that element value to 10 and exits the loop.

In the first UPDATE statement, **x** is a derived-column name used to update the current element in the collection-derived table. The second UPDATE statement updates the base table **table1** with the new collection.

For information on how to use **collection** host variables in Informix® ESQL/C programs, see the discussion of complex data types in the *Informix® ESQL/C Programmer's Manual*.

## Example of Inserting a Value into a Multiset Collection

Suppose the Informix® ESQL/C host variable **a\_multiset** has the following declaration:

```
EXEC SQL BEGIN DECLARE SECTION;
    client collection multiset(integer not null) a_multiset;
EXEC SQL END DECLARE SECTION;
```

The following INSERT statement adds a new MULTISSET element of 142,323 to **a\_multiset**:

```
EXEC SQL allocate collection :a_multiset;
EXEC SQL select multiset_col into :a_multiset from table1
    where id = 107;
EXEC SQL insert into table(:a_multiset) values (142323);
EXEC SQL update table1 set multiset_col = :a_multiset
    where id = 107;

EXEC SQL deallocate collection :a_multiset;
```

When you insert elements into a **client-collection** variable, you cannot specify a SELECT statement or an EXECUTE FUNCTION statement in the VALUES clause of the INSERT. When you insert elements into a **server-collection** variable, however, the SELECT and EXECUTE FUNCTION statements are valid in the VALUES clause. For more information on **client-** and **server-collection** variables, see the *Informix® ESQL/C Programmer's Manual*.

## Accessing a Nested Collection

If the element of the collection is itself a complex type (**collection** or **row** type), the collection is a *nested collection*. For example, suppose the Informix® ESQL/C **collection** variable, **a\_set**, is a nested collection that is defined as follows:

```
EXEC SQL BEGIN DECLARE SECTION;
    client collection set(list(integer not null)) a_set;
    client collection list(integer not null) a_list;
    int an_int;
EXEC SQL END DECLARE SECTION;
```

To access the elements (or fields) of a nested collection, use a **collection** or **row** variable that matches the element type (**a\_list** and **an\_int** in the preceding code fragment) and a Select cursor.

## Accessing a Row Variable

The TABLE keyword can make the Informix® ESQL/C **row** variable a collection-derived table. That is, a row appears as a table in an SQL statement. For a **row** variable, think of the collection-derived table as a table of one row, with each field of the **row** type being a column of the row. Use the TABLE keyword in place of the name of a table, synonym, or view in these SQL statements:

- The FROM clause of the SELECT statement to access a field of the **row** variable
- The UPDATE statement to modify an existing field in the **row** variable

The DELETE and INSERT statements do not support a **row** variable in the collection-derived-table segment.

For example, suppose an ESQL/C host variable **a\_row** has the following declaration:

```
EXEC SQL BEGIN DECLARE SECTION;
    row(x int, y int, length float, width float) a_row;
EXEC SQL END DECLARE SECTION;
```

The following ESQL/C code fragment adds the fields in the **a\_row** variable to the **row\_col** column of the **tab\_row** table:

```
EXEC SQL update table(:a_row)
    set x=0, y=0, length=10, width=20;
EXEC SQL update rectangles set rect = :a_row;
```

## Database Name

Use the Database Name segment to specify the name of a database. Use this segment when you see a reference to a database name in a syntax diagram.

### Syntax

Database Name

*dbname*

@*dbservername*

'//*dbservername/dbname*'

<sup>669</sup>*db\_var*

| Element             | Description   | Restrictions   | Syntax                                  |
|---------------------|---|--|---|
| <i>dbname</i>       | Database name (with no pathname nor database server name)   | Must be unique among the names of databases of the database server   | <a href="#">Identifier on page 1456</a> |
| <i>dbservername</i> | Database server on which the database <i>dbname</i> resides | Must exist. No blank space can separate @ from <i>dbservername</i> . | <a href="#">Identifier on page 1456</a> |
| <i>db_var</i>       | Host variable whose value specifies a database environment  | Variable must be a fixed-length character data type                  | Language specific                       |

### Usage

Database names are not case sensitive. You cannot use delimited identifiers for a database name.

The identifiers *dbname* and *dbservername* can each have a maximum of 128 bytes.

If the name of a database server is a delimited identifier or if it includes uppercase letters, that database server cannot participate in cross-server distributed DML operations. To avoid this restriction, use only undelimited names that include no uppercase letters when you declare the name or the alias of a database server.

In a nondefault locale, *dbname* can include alphabetic characters from the code set of the locale. In a locale that supports a multibyte code set, keep in mind that the maximum length of the database name refers to the number of bytes, not the number of characters. For more information on the GLS aspects of naming databases, see the *Informix® GLS User's Guide*.

669. ESQL/C only

## Using Keywords as Table Names

You can choose a database on another database server as your current database by specifying a database server name. The database server that *dbservername* specifies must match the name of a database server that is listed in your **sqlhosts** information.

## Using the @ Symbol

The @ symbol is a literal character. If you specify a database server name, blank spaces are not valid between the @ symbol and the database server name. Either put a blank space between *dbname* and the @ symbol, or omit the blank space.

The following examples show valid database specifications, qualified by the database server name:

```
empinfo@personnel  
empinfo @personnel
```

In these examples, **empinfo** is the name of the database and **personnel** is the name of the database server.

## Using a Path-Type Naming Notation

If you specify a pathname, do not put blank spaces between the quotation marks, slashes, and names. The following example specifies a valid UNIX™ pathname:

```
'//personnel/empinfo'
```

Here **empinfo** is the *dbname* and **personnel** is the name of the database server.

## Using a Host Variable

You can use a host variable within an ESQL/C application to store a value that represents a database environment.

---

[DEFINE on page 1089](#)

## Database Object Name

Use the Database Object Name segment to specify the name of a database object, such as a column, table, view, or user-defined routine. Use this segment whenever you see a reference to a database object name.

## Syntax

Database Object Name

<sup>670</sup> *database*

*@dbservername*

:

Owner Name<sup>671</sup>

.

*object*

*. object*

| Element             | Description                          | Restrictions                             | Syntax                                     |
|---------------------|--------------------------------------|--|--|
| <i>database</i>     | Database where <i>object</i> resides | Must exist.                              | <a href="#">Database Name on page 1449</a> |
| <i>dbservername</i> | Database server of <i>database</i>   | Must exist. No space after @.            | <a href="#">Identifier on page 1456</a>    |
| <i>object</i>       | Name of a database object            | See <a href="#">Usage on page 1451</a> . | <a href="#">Identifier on page 1456</a>    |

## Usage

A database object name can include qualifiers and separator symbols to specify a database, a server, an owner, and (for some objects) another object of which the current database object is a component. For example, this expression specifies the **unit-price** column of the **stock** table, owned by user **informix**, in the **stores\_demo** database of a database server called **butler**:

```
stores_demo@butler:informix.stock.unit_price
```

If you are creating or renaming a database object, the new name that you declare must be unique among objects of the same type in the database. Thus, the name of a new view must be unique among the names and synonyms of tables, views, and sequence objects that already exist in the same database. (But a view can have the same name as a view in a different database of the same server, or the same name as a trigger, for example, because these are different types of objects.)

In an ANSI-compliant database, the *owner.object* combination must be unique in the database for the type of object. A database object specification must include the owner name for a database object that you do not own. For example, if you specify a table that you do not own, you must also specify the owner of the table. The owner of all the system catalog tables is **informix**.

In Informix®, the uniqueness requirement does not apply to the name of a user defined routine (UDR). For more information, see [Routine Overloading and Routine Signatures on page 1454](#).

Characters from the code set of your database locale are valid in database object names. For more information, see *Informix® GLS User's Guide*.

## Specifying a Database Object in an External Database

Besides objects in the local database to which you are currently connected, you can also specify a database object in another database of the local database server, or in a database of a remote database server.

670. Informix® extension

671. See [Owner name on page 1488](#)

## Specifying a Database Object in a Cross-Database Query

To specify an object in another database of the local database server, you must qualify the identifier of the object with the name of the database (and of the owner, if the external database is ANSI compliant), as in this example:

```
corp_db:hrdirector.executives
```

In this example, the name of the external database is **corp\_db**. The name of the owner of the table is **hrdirector**. The name of the table is **executives**. Here the colon (:) separator is required after the *database* qualifier.

In Informix®, queries and other data manipulation language (DML) operations on other databases of the local database server can access most of the *built-in opaque data types*, as listed in [Data Types in Cross-Database Transactions on page 779](#). DML operations can also access user-defined data types (UDTs) that can be cast to built-in types, as well as DISTINCT types that are based on built-in types, if each DISTINCT types and UDT is cast explicitly to a built-in type, and if all the DISTINCT types, UDTs, and casts are defined in all of the participating databases. The same data-type restrictions also apply to the arguments and to the returned values of a user-defined routine (UDR) that accesses other databases of the local Informix® instance, if the UDR is defined in all of the participating databases.

## Specifying a Database Object in a Cross-Server Query

To specify an object in a database of a remote database server, you must use a *fully-qualified identifier* that specifies the database, the database server instance, and the owner (if the external database is ANSI compliant), in addition to the database object name.

For example, **hr\_db@remoteoffice:hrmanager.employees** is a fully-qualified table name.

- Here the database name is **hr\_db**,
- the @ separator (ASCII 64), with no blank spaces, is required between the *database* and *database server* qualifiers,
- the database server name is **remoteoffice**,
- the : separator (ASCII 58), with no blank spaces, is required between the *database server* and *owner* qualifiers,
- the authorization identifier of the table *owner* is **hrmanager**,
- the . separator (ASCII 46), with no blank spaces, is required between the *owner* and *table* qualifiers,
- and the *table* name is **employees**.

Cross-server queries can access columns of built-in data types that are not opaque data types, but they cannot access UDTs nor complex data types. Among built-in opaque types, only BOOLEAN, BSON, JSON, VARCHAR, and DISTINCT types based on those base types, can be accessed or returned by DML statements or by UDRs in the databases of remote server instances. (For more information about the DISTINCT and built-in OPAQUE data types that Informix® supports in cross-server operations, see [Data Types in Cross-Server Transactions on page 781](#).)

If a UDR exists on a remote database server instance, you must specify a fully-qualified identifier for the UDR. The following SQL statement invokes a routine in the same remote database as the previous example, where the authorization identifier of the owner of the routine is **johan**, and the identifier of the UDR is **suggestion\_box**:

```
EXECUTE FUNCTION hr_db@remoteoffice:johan.suggestion_box(0):
```

You can refer to a remote database object only in the following SQL statements:

- CREATE DATABASE
- CREATE SYNONYM
- CREATE VIEW
- DATABASE
- DELETE
- EXECUTE FUNCTION
- EXECUTE PROCEDURE
- INFO
- INSERT
- LOAD
- LOCK TABLE
- MERGE
- SELECT
- UNLOAD
- UNLOCK TABLE
- UPDATE

In distributed MERGE operations, source tables can be in the database of a remote server instance, but the target table must be in a database of the local Informix instance.

For information on the support in these statements across databases of the local server, or across database servers, refer to the *Informix® Guide to SQL: Tutorial*.

If the name of a database server is a delimited identifier or if it includes uppercase letters, that database server cannot participate in distributed DML operations. To avoid this restriction, use only undelimited names that include no uppercase letters when you declare the name or the alias of a database server.

### **Restrictions on remote user-defined routines**

The EXECUTE FUNCTION or EXECUTE PROCEDURE statement can invoke a routine in the database of a remote server instance in most contexts where a UDR is valid in the local database, but every participating database must have the same logging mode.

Cross-server operations require exactly one *coordinator* to connect to one or more database server instances as subordinate *participants* that process branches of the operation that reads or modifies objects in their databases.

Only the database server instance that initiated the cross-server operation as the coordinator can establish a connection with another database server. A distributed operation that invokes UDRs on one or more remote database servers can have a logical topology of connections resembling a star schema, but not a snowflake schema. In the one-to-many relationship between the coordinator and participants, only the coordinator can be the calling context for invoking remote UDRs.

If the EXECUTE FUNCTION or EXECUTE PROCEDURE statement calls a remote routine that in turn attempts to execute a remote routine on a third database server instance, the distributed operation fails with error -556. A UDR called from a participant server cannot invoke a UDR on a third server, and cannot reference any object on a third server.

## Routine Overloading and Routine Signatures

Because of routine overloading, the name of a user-defined routine does not need to be unique to the database. You can define more than one UDR with the same name, provided that the *routine signature* for each UDR is different.

UDRs are uniquely identified by their signatures. The signature of a UDR includes the following items of information:

- The type of routine (function or procedure)
- The identifier of the routine
- The cardinality, data type, and order of the parameters
- In an ANSI-compliant database, the owner name

For any given UDR, at least one item in the routine signature must be unique among all the UDRs registered in the database.

In a database that is not ANSI-compliant, two routines that have different owners cannot have the same signature, except in the special cases of the **sysdbopen()** and **sysdbclose()** routines. For information about the effects of these session configuration routines when their owners connect to or disconnect from a database where these routines are defined, see [IFX\\_REPLACE\\_MODULE Function](#).

## Specifying an Existing UDR

To reference an existing UDR by a name that does not uniquely identify the UDR, you must also specify the parameter data types after the UDR name, in the same order that they were declared when the UDR was created. Informix® then uses routine resolution rules to identify the instance of the UDR to alter, drop, or execute. As an alternative, you can specify its *specific name*, if one was declared when the UDR was created. Specific names are described in the section [Specific Name on page 1521](#). For more details of routine resolution, see [Comparing Arguments to the Parameter List on page 1434](#), and *Informix® User-Defined Routines and Data Types Developer's Guide*.

## Owners of Objects Created by UDRs

When a DDL statement within an owner-privileged UDR creates a new database object, the owner of the routine (rather than the user who executes it, if that user is not the owner of the routine) becomes the owner of the new database object. For a DBA-privileged UDR, however, the user who executes the routine (and who must hold DBA privilege) becomes the owner of any objects that the UDR creates.

## External Routine Reference

Include the External Routine Reference clause when you write an external routine. This option is not available for SPL routines.

## Syntax

External Routine Reference

### EXTERNAL NAME

Shared-Object Filename<sup>674</sup>

### LANGUAGE

#### C JAVA

### PARAMETER STYLE

#### INFORMIX

672 673

### VARIANT NOT VARIANT

## Usage

If the IFX\_EXTEND\_ROLE configuration parameter is set to `ON` or to `1`, authorization to use this segment is available only to the Database Server Administrator (DBSA), and to users whom the DBSA has granted the EXTEND role. By default, the DBSA is user **informix**. In addition, you cannot create an external routine unless you hold the Resource or DBA privilege on the database, and also hold the Usage privilege on the external programming language in which the routine is written. For the syntax of the GRANT USAGE ON LANGUAGE C and GRANT USAGE ON LANGUAGE JAVA statements of SQL, see [Language-Level Privileges on page 607](#).

This segment specifies the following information about an external routine:

- Pathname to the executable object code, stored in a shared-object file  
For C routines, this file is either a DLL or a shared library, depending on your operating system.  
For Java™ routines, this file is a jar file. Before you can create a UDR written in the Java™ language, you must assign a jar identifier to the external jar file with the `sqlj.install_jar` procedure. For more information, see `sqlj.install_jar`.
- The name of the programming language in which the UDR is written
- The parameter style of the UDR  
By default, the parameter style is INFORMIX. (This implies that if you specify OUT or INOUT parameters, the OUT or INOUT values are passed by reference.)
- The VARIANT or NOT VARIANT option. If you specify neither, the default is VARIANT. If the routine includes any statement of SQL it is a VARIANT routine. If a DDL statement that includes the External Routine Reference clause also includes the Routine Modifier clause, do not classify the same UDR as VARIANT in one of these clauses and as NOT VARIANT in the other.

## Example

The following example includes an external routine reference for a Java™ language UDR. You must first register `demo_jar` using the procedure `install_jar(<absolute path><jar file name>,<internal registered name>)`.

```
CREATE FUNCTION delete_order(int) RETURNING int
EXTERNAL NAME 'informix.demo_jar:delete_order.delete_order()'
```

672. C

673. Java™

674. See [Shared-Object Filename on page 1518](#)

```
LANGUAGE JAVA;
```

### Related reference

[Shared-Object Filename on page 1518](#)

## VARIANT or NOT VARIANT Option

A function is *variant* if it can return different results when it is invoked with the same arguments or if it modifies the state of a database or of a variable. For example, a function that returns the current date or time is a variant function.

By default, user-defined functions are variant. If you specify NOT VARIANT when you create or modify a function, it cannot contain any SQL statements.

If the function is nonvariant, the database server might cache the return variant functions. For more information on functional indexes, see [CREATE INDEX statement on page 253](#).

To register a nonvariant function, add the NOT VARIANT option in this clause or in the Routine Modifier clause that is discussed in [Routine modifier on page 1506](#). If you specify the modifier in both contexts, however, you must use the same modifier (either VARIANT or NOT VARIANT) in both clauses.

## Example of a C User-Defined Function

The next example registers an external function named **equal()** that takes two **point** data type values as arguments. In this example, **point** is an opaque data type that specifies the **x** and **y** coordinates of a two-dimensional point.

```
CREATE FUNCTION equal( a point, b point ) RETURNING BOOLEAN;  
  EXTERNAL NAME "/usr/lib/point/lib/libbtype1.so(point1_equal)"  
  LANGUAGE C  
END FUNCTION;
```

The function returns a single value of type BOOLEAN. The external name specifies the path to the C shared-object file where the object code of the function is stored. The external name indicates that the library contains another function, **point1\_equal()**, which is invoked while **equal()** executes.

## Identifier

An *identifier* specifies the unqualified name of a database object, such as an access method, aggregate, alias, blob space, cast, column, constraint, correlation, data type, index, operator class, partition, procedure, table, trigger, sequence, synonym, or view. Use the Identifier segment whenever you see a reference to an identifier in a syntax diagram.

## Syntax

Identifier

*letter underscore*

*letter digit underscore*

*dollar\_sign*

Delimited Identifier<sup>675</sup>

| Element            | Description                                | Restrictions  | Syntax                                      |
|--------------------|--|---|---|
| <i>digit</i>       | Integer in range 0 to 9                    | Cannot be the first character   | <a href="#">Literal Number on page 1419</a> |
| <i>dollar_sign</i> | Dollar ( \$ ) symbol                       | Cannot be the first character   | Literal symbol entered from the keyboard.   |
| <i>letter</i>      | Upper- or lowercase letter of the alphabet | In the default locale, must be an ASCII character in the range A to Z or a to z | Literal symbol entered from the keyboard.   |
| <i>underscore</i>  | Underscore ( _ ) character                 | Cannot substitute a space, hyphen, or other non-alphanumeric character          | Literal symbol entered from the keyboard.   |

## Usage

This is a logical subset of [Database Object Name on page 1450](#), a segment that can specify the *owner*, *database*, and *database server* of external objects.

To include other non-alphanumeric symbols, such as a blank space (ASCII 32), in an identifier, you must use a delimited identifier. It is recommended that you do not use the dollar sign ( \$ ) in identifiers, because this symbol is a special character whose inclusion in an identifier might cause conflicts with other syntax elements. For more information, see [Delimited Identifiers on page 1458](#).

An identifier must have a length of at least 1 byte, but no more than 128 bytes. For example, **employee\_information** is valid as a table name. If you are using a multibyte code set, keep in mind that the maximum length of an identifier refers to the number of bytes, not to the number of logical characters.

For letter characters in nondefault locales, see [Support for Non-ASCII Characters in Identifiers on page 1458](#). For further information on the GLS aspects of identifiers, see Chapter 3 of the *Informix® GLS User's Guide*.

When you use ESQL/C with Informix®, the database server checks the internal version number of the client application and the setting of the **IFX\_LONGID** environment variable to determine whether a client application supports long identifiers (up to 128 bytes in length). For more information, see the *Informix® Guide to SQL: Reference*.

When the database server uses long identifiers, you might encounter error messages, warning messages, or other messages that truncate trailing characters in SQL identifiers or elsewhere in the message text. Truncation can usually be avoided, however, if identifiers have 18 or fewer bytes. Your code might be difficult to read or to maintain if identifiers of different SQL objects are identical in their first 18 characters.

---

675. See [Delimited Identifiers on page 1458](#)

## Use of Uppercase Characters

You can specify the name of a database object with uppercase characters, but the database server shifts these to lowercase characters unless the **DELIMIDENT** environment variable is set and the identifier of the database object is enclosed between double ( " ) quotation marks. In this case, the database server treats the name of the database object as a delimited identifier and preserves the uppercase characters in the name, as described in [Delimited Identifiers on page 1458](#).

If the name of a database server includes uppercase letters, that database server cannot participate in distributed DML operations. To avoid this restriction, use only un delimited names that include no uppercase letters when you declare the name or the alias of a database server.

## Use of Keywords as Identifiers

Although you can use almost any word as an identifier, syntactic ambiguities can result from using keywords as identifiers in SQL statements. The statement might fail or might not produce the expected results. For a discussion of the syntactic ambiguities that can result from using keywords as identifiers and an explanation of workarounds for these problems, see [Potential Ambiguities and Syntax Errors on page 1461](#).

Delimited identifiers provide the easiest and safest way to use a keyword as an identifier without syntactic ambiguities. No workarounds are necessary for a keyword as a delimited identifier. For the syntax and usage of delimited identifiers, see [Delimited Identifiers on page 1458](#). Delimited identifiers require, however, that your code always use single ( ' ) quotation marks, rather than double ( " ) quotation marks, to delimit character-string literals.

For the keywords of the implementation of SQL in Informix®, see [Keywords of SQL for HCL Informix on page 1527](#).

**Tip:** If an error message seems unrelated to the statement that caused the error, check to see if the statement uses a keyword as an un delimited identifier.

## Support for Non-ASCII Characters in Identifiers

In a non default locale, you can use any alphabetic character that your locale recognizes as a *letter* in an SQL identifier. This feature enables you to use non-ASCII characters in the names of some database objects. For objects that support non-ASCII characters, see the *Informix® GLS User's Guide*.

## Delimited Identifiers

By default, the character set of a valid SQL identifier is restricted to letters, digits, underscore, and dollar-sign symbols. If you set the **DELIMIDENT** environment variable, however, SQL identifiers can also include additional characters from the code set implied by the setting of the **DB\_LOCALE** environment variable.

Delimited Identifier

```
"
letter digit underscore other_character
"
```

| Element                | Description  | Restrictions  | Syntax                                      |
|------------------------|--|---|---|
| <i>digit</i>           | Integer in the range 0 to 9                                      | Cannot be the first character                             | <a href="#">Literal Number on page 1419</a> |
| <i>letter</i>          | Letter that forms part of the delimited identifier               | Letters in delimited identifiers are case-sensitive       | Literal value entered from the keyboard.    |
| <i>other_character</i> | Nonalphanumeric character, such as #, \$, or blank space         | Must be an element in the code set of the database locale | Literal value entered from the keyboard.    |
| <i>underscore</i>      | Underscore ( <code>_</code> ) symbol in the delimited identifier | Cannot include more than 128                              | Literal value entered from the keyboard.    |

If the database supports delimited identifiers, any double quotation marks ( `"` ) enclose an SQL identifier in your code, and only single ( `'` ) quotation marks, rather than double ( `"` ) quotation marks, delimit character-string literals.

Delimited identifiers enable you to declare names that are otherwise identical to SQL keywords, such as TABLE, WHERE, DECLARE, and so on. The only type of object for which you cannot specify a delimited identifier is a database name.

Letters in delimited identifiers are case sensitive. If you are using the default locale, *letter* must be an upper- or lowercase character in the range a to z or A to Z (in the ASCII code set). If you are using a nondefault locale, *letter* must be an alphabetic character that the locale supports. For more information, see [Support for Non-ASCII Characters in Delimited Identifiers \(GLS\) on page 1460](#).

Delimited identifiers are compliant with the ANSI/ISO standard for SQL.

When you create a database object, avoid including leading blank spaces or other white-space characters between the first delimiting quotation mark and the first nonblank character of the delimited identifier. (Otherwise, you might not be able to reference the object in some contexts.)

If the name of a database server is a delimited identifier or if it includes uppercase letters, that database server cannot participate in distributed DML operations. To avoid this restriction, use only undelimited names that include no uppercase letters when you declare the name or the alias of a database server.

## Support for Nonalphanumeric Characters

By default, ASCII letters, digits, and the underscore (ASCII 95) character are supported in SQL identifiers and in storage object identifiers for all locales. To include additional characters from the codeset implied by the **DB\_LOCALE** setting in the names of database objects, you must use delimited identifiers.

You cannot, however, use delimited identifiers, however, to specify characters that are not letters, digits, or the underscore ( `_` ) character when you declare or reference the names of storage objects, such as dbspaces, partitions, blobspaces, or sbspaces.

## Support for Non-ASCII Characters in Delimited Identifiers (GLS)

When you are using a nondefault locale whose code set supports non-ASCII characters, you can specify those non-ASCII characters in most delimited identifiers. The rule is that if you can specify non-ASCII characters in the undelimited form of the identifier, you can also specify non-ASCII characters in the delimited form of the same identifier. For a list of identifiers that support non-ASCII characters and for information on non-ASCII characters in delimited identifiers, see the *Informix® GLS User's Guide*.

## Enabling Delimited Identifiers

### About this task

To use delimited identifiers, you must set the **DELIMIDENT** environment variable. While **DELIMIDENT** is set, strings enclosed in double quotation marks ( `"` ) are treated as identifiers of database objects, and strings enclosed in single quotation marks ( `'` ) are treated as literal strings. If the **DELIMIDENT** environment variable is not set, however, strings enclosed in double quotation marks are also treated as literal strings.

If **DELIMIDENT** is set, the SELECT statement in the following example must be in single quotation marks in order to be treated as a quoted string:

```
PREPARE ... FROM 'SELECT * FROM customer';
```

If a delimited identifier is used in the SELECT statement that defines a view, then the **DELIMIDENT** environment variable must be set in order for the view to be accessed, even if the view name itself contains no special characters.

On UNIX™ and Linux™ systems, you can set **DELIMIDENT** by the procedures for setting environment variables that are described in *Informix® Guide to SQL: Reference*.

On Windows™ systems, you can set **DELIMIDENT** in various ways, which generally have the following descending order of precedence:

1. The setting of **DELIMIDENT** in the connection string when connecting
2. The setting of the `SQL_INFX_ATTR_DELIMIDENT` connection attribute before connecting
3. The setting of **DELIMIDENT** in **setnet32** with the **Use my settings** box selected
4. The setting of **DELIMIDENT** in **setnet32** with the **Use my settings** box cleared
5. The setting of **DELIMIDENT** on the command line before running the application
6. The setting of **DELIMIDENT** in Windows™ as a user variable
7. The setting of **DELIMIDENT** in Windows™ as a system variable
8. The default value (of no support for delimited identifiers).

This general order of precedence for Windows™ clients is sensitive, however, to the API through which you connect to the database, which can also affect the meaning of the setting and the default value. Refer to the documentation of your specific API for more information about the **DELIMITED** setting in Windows™.

## Examples of Delimited Identifiers

The next example shows how to create a table with a case-sensitive name:

```
CREATE TABLE "Proper_Ranger" (...);
```

The following example creates a table whose name includes a white-space character. If the table name were not enclosed by double (") quotation marks, and if **DELIMITED** were not set, you could not use a blank space in the identifier.

```
CREATE TABLE "My Customers" (...);
```

The next example creates a table that has a keyword as the table name:

```
CREATE TABLE "TABLE" (...);
```

The following example for Informix® shows how to delete all the rows from a table that is named FROM when you omit the keyword FROM in the DELETE statement:

```
DELETE FROM;
```

## Using Double Quotation Marks in a Delimited Identifier

To include a double quotation mark (") character within a delimited identifier, you must precede the double quotation mark (") with another double quotation mark ("). The following statement fragment specifies **My "Good" Data** as a table name:

```
CREATE TABLE "My ""Good"" Data" (...);
```

## Potential Ambiguities and Syntax Errors

does not recommend using any keyword of SQL as an identifier, because to do so tends to make your code more difficult to read and to maintain. If you ignore this potential problem for human readers, however, you can use almost any keyword as an SQL identifier, but various syntactic ambiguities can occur. An ambiguous statement might not produce the desired results. The following sections identify some potential ambiguities and workarounds when keywords are declared as identifiers, or when different database objects have the same identifier.

## Using the Names of Built-In Functions as Column Names

The following two examples show a workaround for using a built-in function as a column name in a SELECT statement. This workaround applies to the built-in aggregate functions (AVG, COUNT, MAX, MIN, SUM) as well as the function expressions (algebraic, exponential and logarithmic, time, HEX, length, DBINFO, trigonometric, and TRIM functions).

Using **avg** as a column name causes the next example to fail because the database server interprets **avg** as an aggregate function rather than as a column name:

```
SELECT avg FROM mytab; -- fails
```

If the **DELIMITED** environment variable is set, you could use **avg** as a column name as the following example shows:

```
SELECT "avg" from mytab; -- successful
```

The workaround in the following example removes ambiguity by including a table name with the column name:

```
SELECT mytab.avg FROM mytab;
```

If you use the keyword **TODAY**, **CURRENT**, **SYSDATE**, or **USER** as a column name, ambiguity can occur, as the following example shows:

```
CREATE TABLE mytab (user char(10),
    CURRENT DATETIME HOUR TO SECOND,TODAY DATE);

INSERT INTO mytab VALUES('josh','11:30:30','1/22/2008');

SELECT user,current,today FROM mytab;
```

The database server interprets **user**, **current**, and **today** in the **SELECT** statement as the built-in functions **USER**, **CURRENT**, and **TODAY**. Thus, instead of returning `josh, 11:30:30,1/22/2008`, the **SELECT** statement returns the current user name, the current time, and the current date. The **SYSDATE** keyword has a similar effect in databases of Informix®.

If you want to select the actual columns of the table, you must write the **SELECT** statement in one of the following ways:

```
SELECT mytab.user, mytab.current, mytab.today FROM mytab;

EXEC SQL select * from mytab;
```

## Using Keywords as Column Names

Specific workarounds exist for using a keyword as a column name in a **SELECT** statement or other SQL statement. In some cases, more than one suitable workaround might be available.

### Using ALL, DISTINCT, or UNIQUE as a Column Name

If you want to use the **ALL**, **DISTINCT**, or **UNIQUE** keywords as column names in a **SELECT** statement, you can take advantage of a workaround.

First, consider what happens when you try to use one of these keywords without a workaround. In the following example, using **all** as a column name causes the **SELECT** statement to fail because the database server interprets **all** as a keyword rather than as a column name:

```
SELECT all FROM mytab -- fails;
```

You must use a workaround to make this **SELECT** statement execute successfully. If the **DELIMITED** environment variable is set, you can use **all** as a column name by enclosing **all** in double quotation marks. In the following example, the **SELECT** statement executes successfully because the database server interprets **all** as a column name:

```
SELECT "all" from mytab; -- successful
```

The workaround in the following example uses the keyword ALL with the column name **all**:

```
SELECT ALL all FROM mytab;
```

The examples that follow show workarounds for using the keywords UNIQUE or DISTINCT as a column name in a CREATE TABLE statement.

The next example fails to declare a column named **unique** because the database server interprets **unique** as a keyword rather than as a column name:

```
CREATE TABLE mytab (unique INTEGER); -- fails
```

The following workaround uses two SQL statements. The first statement creates the column **mycol**; the second statement renames the column **mycol** to **unique**:

```
CREATE TABLE mytab (mycol INTEGER);
RENAME COLUMN mytab.mycol TO unique;
```

The workaround in the following example also uses two SQL statements. The first statement creates the column **mycol**; the second alters the table, adds the column **unique**, and drops the column **mycol**:

```
CREATE TABLE mytab (mycol INTEGER);
ALTER TABLE mytab
  ADD (unique INTEGER),
  DROP (mycol);
```

## Using INTERVAL or DATETIME as a Column Name

The examples in this section show workarounds for using the keyword INTERVAL (or DATETIME) as a column name in a SELECT statement.

Using **interval** as a column name causes the following example to fail because the database server interprets **interval** as a keyword and expects it to be followed by an INTERVAL qualifier:

```
SELECT interval FROM mytab; -- fails
```

If the **DELIMITED** environment variable is set, you could use **interval** as a column name, as the following example shows:

```
SELECT "interval" from mytab; -- successful
```

The workaround in the following example removes ambiguity by specifying a table name with the column name:

```
SELECT mytab.interval FROM mytab;
```

The workaround in the following example includes an owner name with the table name:

```
SELECT josh.mytab.interval FROM josh.mytab;
```

## Using rowid as a Column Name

Every nonfragmented table has a virtual column named **rowid**. To avoid ambiguity, you cannot use **rowid** as a column name. Performing the following actions causes an error:

- Creating a table or view with a column named **rowid**
- Altering a table by adding a column named **rowid**
- Renaming a column to **rowid**

You can, however, use the term **rowid** as a table name.

```
CREATE TABLE rowid (column INTEGER, date DATE, char CHAR(20));
```

**Important:** It is recommended that you use primary keys as an access method, rather than exploiting the **rowid** column.

## Using keywords as table names

The database server issues an error in contexts where the unqualified identifier of a table object is also a valid keyword of SQL. You can disambiguate the table name by qualifying it with the authorization identifier of the owner of the table.

Examples that follow illustrate owner-name qualifiers as workarounds when the keyword **STATISTICS**, **OUTER**, or **FROM** has been declared as a table name or synonym. (These examples also apply if any of those keywords is the identifier of a view.)

Using **statistics** as a table identifier causes the following UPDATE statement example to fail. An exception occurs because the database server interprets **statistics** as a keyword in a syntactically incorrect UPDATE STATISTICS statement, rather than as the target table name in an UPDATE statement:

```
UPDATE statistics SET mycol = 10; -- fails
```

The workaround in the following example qualifies the table name with the owner name, to avoid that ambiguity:

```
UPDATE josh.statistics SET mycol = 10;
```

Using **outer** as a table name causes the following example to fail, because the database server interprets **outer** as a keyword for performing a syntactically incorrect outer join:

```
SELECT mycol FROM outer; -- fails
```

The following successful example uses owner naming to avoid ambiguity:

```
SELECT mycol FROM josh.outer;
```

The following DELETE statement, whose target table was created with **from** as its identifier, returns a syntax error:

```
DELETE from; -- fails
```

Because **FROM** is also an optional keyword that immediately precedes the name of the table whose records are to be destroyed, the database server expects a table name after **FROM**. Finding none, it issues an exception.

The following example, in contrast, deletes all the rows from what it correctly recognizes as the **from** table, because that table name is qualified by the name of its owner:

```
DELETE zelaine.from;
```

If the **DELIMIDENT** environment variable is set on the database server, an alternative workaround is to use double quotation marks ( " ) as delimiters.

```
DELETE "from";
```

This avoids the exception by indicating that **from** is an SQL identifier, rather than a string literal or an SQL keyword.

Despite the availability of these workarounds, your code will be easier for humans to read and to maintain if you avoid declaring SQL keywords as the identifiers of tables, views, or other database objects.

## Workarounds that Use the Keyword AS

In some cases, although a statement is not ambiguous and the syntax is correct, the database server returns a syntax error. The preceding pages show existing syntactic workarounds for several situations. You can use the AS keyword to provide a workaround for the exceptions.

You can use the AS keyword in front of column labels or table aliases.

The following example uses the AS keyword with a column label:

```
SELECT column_name AS display_label FROM table_name;
```

The following example uses the AS keyword with a table alias:

```
SELECT select_list FROM table_name AS table_alias;
```

## Using AS with Column Labels

The examples in this section show workarounds that use the AS keyword with a column label. The first two examples show how you can use the keyword UNITS (or YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, or FRACTION) as a column label.

Using **units** as a column label causes the next example to fail because the database server interprets it as part of an INTERVAL expression in which the **mycol** column is the operand of the UNITS operator:

```
SELECT mycol units FROM mytab;
```

The workaround in the following example includes the AS keyword:

```
SELECT mycol AS units FROM mytab;
```

The following example uses the AS or FROM keyword as a column label.

Using **as** as a column label causes the following example to fail because the database server interprets **as** as identifying **from** as a column label and thus finds no required FROM clause:

```
SELECT mycol as from mytab; -- fails
```

The following successful example repeats the AS keyword:

```
SELECT mycol AS as from mytab;
```

Using **from** as a column label causes the following example to fail because the database server expects a table name to follow the first **from**:

```
SELECT mycol from FROM mytab; -- fails
```

This example uses the AS keyword to identify the first **from** as a column label:

```
SELECT mycol AS from FROM mytab;
```

## Using AS with Table Aliases

Examples in this section show workarounds that use the AS keyword with a table alias. The first pair shows how to use the ORDER, FOR, GROUP, HAVING, INTO, UNION, WITH, CREATE, GRANT, or WHERE keyword as a table alias.

Using **order** as a table alias causes the following example to fail because the database server interprets **order** as part of an ORDER BY clause:

```
SELECT * FROM mytab order; -- fails
```

The workaround in the following example uses the keyword AS to identify **order** as a table alias:

```
SELECT * FROM mytab AS order;
```

The next two examples show how to use the keyword WITH as a table alias.

Using **with** as a table alias causes the next example to fail because the database server interprets **with** as part of the WITH CHECK OPTION syntax:

```
EXEC SQL select * from mytab with; -- fails
```

The workaround in the following example uses the keyword AS to identify **with** as a table alias:

```
EXEC SQL select * from mytab as with; -- succeeds
```

The next two examples use the keyword CREATE as a table alias. Using **create** as a table alias causes the next example to fail because the database server interprets the keyword as part of the syntax to create a new database object, such as a table, synonym, or view:

```
EXEC SQL select * from mytab create; -- fails
```

```
EXEC SQL select * from mytab as create; -- succeeds
```

The workaround uses the keyword AS to identify **create** as a table alias. (Using grant as an alias would similarly fail, but is valid after the AS keyword.)

## Fetching Cursors that have Keywords as Names

In a few situations, no workaround exists for the syntactic ambiguity that occurs when a keyword is used as an identifier in an SQL program.

In the following example, the FETCH statement specifies a cursor named **next**. The FETCH statement generates a syntax error because the preprocessor interprets **next** as a keyword, signifying the next row in the active set and expects a cursor name to follow **next**. This occurs whenever the keyword NEXT, PREVIOUS, PRIOR, FIRST, LAST, CURRENT, RELATIVE, or ABSOLUTE is used as a cursor name:

```
/* This code fragment fails */
EXEC SQL declare next cursor for
    select customer_num, lname from customer;
EXEC SQL open next;
EXEC SQL fetch next into :cnum, :lname;
```

## Declaring keywords as names for variables in UDRs

If you use some keywords as identifiers for variables in a user-defined routine (UDR), you can create ambiguous syntax:

The following constant expressions and other SQL keywords might produce unexpected results as variable names.

- CURRENT
- CURRENT\_ROLE
- CURRENT\_USER
- DATETIME
- DEFAULT\_ROLE
- GLOBAL
- INTERVAL
- NULL
- OFF
- OUT
- PROCEDURE
- SELECT
- SYSDATE
- TODAY
- UNITS
- USER

## Using CURRENT, DATETIME, INTERVAL, and NULL in INSERT

A UDR cannot insert a variable that was declared using the CURRENT, DATETIME, INTERVAL, or NULL keywords as the name. For example, if you declare a variable called **null**, when you try to insert the value **null** into a column, you receive a syntax error, as the following example shows:

```
CREATE PROCEDURE problem()
. . .
DEFINE null INT;
LET null = 3;
INSERT INTO tab VALUES (null); -- error, inserts NULL, not 3
```

### Related reference

[DEFINE on page 1089](#)

## Using NULL and SELECT in a Condition

If you declare a variable with the name **null** or **select**, including it in a condition that uses the IN keyword is ambiguous. The following example shows three conditions that cause problems: in an IF statement, in a WHERE clause of a SELECT statement, and in a WHILE condition:

```
CREATE PROCEDURE problem()
. . .
```

```

DEFINE x,y,select, null, INT;
DEFINE pfname CHAR[15];
LET x = 3; LET select = 300;
LET null = 1;
IF x IN (select, 10, 12) THEN LET y = 1; -- problem if

IF x IN (1, 2, 4) THEN
SELECT customer_num, fname INTO y, pfname FROM customer
  WHERE customer IN (select , 301 , 302, 303); -- problem in

WHILE x IN (null, 2)      -- problem while
. . .
END WHILE;

```

You can use the variable **select** in an IN list if you ensure it is not the first element in the list. The workaround in the following example corrects the IF statement that the preceding example shows:

```
IF x IN (10, select, 12) THEN LET y = 1; -- problem if
```

No workaround exists to using **null** as a variable name and attempting to use that variable in an IN condition.

[DEFINE on page 1089](#)

## Declaring Keywords or Routine Names as SPL Variables

If you declare a variable with the same name as a keyword or as the name of a routine, ambiguities can occur. Informix® uses the following rules for resolving name conflicts among SPL variables, UDR names, and built-in SQL function names.

- Variable names that are declared in DEFINE statements take the highest precedence.
- User-defined routines defined in CREATE PROCEDURE or CREATE FUNCTION statements take precedence over built-in SQL functions.
- Procedures declared with the PROCEDURE keyword in the DEFINE statement take precedence over built-in SQL functions.
- Built-in SQL functions take precedence over SPL procedures that exist in the database but that are not explicitly identified as procedures in the DEFINE statement.

Do not use the name of a built-in SQL function as an SPL variable if you might need to invoke the SQL function. For example, do not declare a variable with the name **count** or **max**, if you might also need to call those aggregate functions.

#### Related reference

[DEFINE on page 1089](#)

## Variables that Conflict with Column Names

If you use the same identifier for an SPL variable and a column name, then within the scope of reference of the variable, the database server interprets any instance of the unqualified identifier as a variable. To use the identifier to specify a column name, use *table.column* notation to qualify the column name with the table name. In the following example, the procedure

variable **lname** is the same as the column name. In the following SELECT statement, **customer.lname** is a column in the database and **lname** is an SPL variable:

```
CREATE PROCEDURE table_test()
DEFINE lname CHAR(15);
LET lname = "Miller";
SELECT customer.lname FROM customer INTO lname
WHERE customer_num = 502;
```

This example is valid, but relying on the rules of precedence of Informix® to resolve name conflicts between SPL variables and column names might make your code difficult for human readers to interpret and to maintain. An alternative to reusing the same identifier as a variable and as a column name is for the DEFINE statement to declare some prefix to the identifier, such as **v\_lname** in this example, to indicate that this variable stores the value of the column **lname**.

## Using ON, OFF, or PROCEDURE with TRACE

If you define an SPL variable called **on**, **off**, or **procedure**, and you attempt to use it in a TRACE statement, the value of the variable is not traced. Instead, the TRACE ON, TRACE OFF, or TRACE PROCEDURE statements execute. You can trace the value of the variable by specifying the variable in a more complex expression.

The following example shows both the ambiguous syntax and workarounds that use arithmetic or string expressions that evaluate to the variable:

```
DEFINE on, off, procedure INT;

TRACE on;                --ambiguous
TRACE 0+ on;  --ok
TRACE off;               --ambiguous
TRACE '||off;--ok

TRACE procedure;  --ambiguous
TRACE 0+procedure;--ok
```

## Using GLOBAL as the Name of a Variable

If you attempt to define a variable with the name **global**, the define operation fails. The syntax that the following example shows conflicts with the syntax for defining global variables:

```
DEFINE global INT; -- fails;
```

If the **DELIMITED** environment variable is set, you could use **global** as a variable name, as the following example shows:

```
DEFINE "global" INT; -- successful
```

**Important:** Although workarounds that the preceding sections show can avoid compilation or runtime syntax conflicts from keywords used as identifiers, keep in mind that such identifiers tend to make code more difficult to understand and to maintain.

## Using EXECUTE, SELECT, or WITH as Cursor Names

Do not use an EXECUTE, SELECT, or WITH keyword as the name of a cursor. If you try to use one of these keywords as the name of a cursor in a FOREACH statement, the cursor name is interpreted as a keyword in the FOREACH statement. No workaround exists.

The following example does not work:

```
DEFINE execute INT;
FOREACH execute FOR SELECT col1 -- error, looks to parser like
  INTO var1 FROM tab1;         -- 'FOREACH EXECUTE PROCEDURE'
```

## SELECT Statements in WHILE and FOR Statements

If you use a SELECT statement in a WHILE or FOR loop, and if you need to enclose it in parentheses, enclose the entire SELECT statement in a BEGIN...END statement block. The SELECT statement in the first WHILE statement in the following example is interpreted as a call to the procedure **var1**; the second WHILE statement is interpreted correctly:

```
DEFINE var1, var2 INT;
WHILE var2 = var1
  SELECT col1 INTO var3 FROM TAB -- error, interpreted as call var1()
  UNION
  SELECT co2 FROM tab2;
END WHILE;

WHILE var2 = var1
  BEGIN
    SELECT col1 INTO var3 FROM TAB -- ok syntax
    UNION
    SELECT co2 FROM tab2;
  END
END WHILE;
```

## SET keyword in the ON EXCEPTION statement of SPL

If you include an SQL statement that begins with the keyword `SET` in the ON EXCEPTION statement, you must enclose it in a BEGIN ... END statement block.

The following list shows some of the SQL statements that begin with the keyword SET:

- SET AUTOFREE
- SET CONNECTION
- SET CONSTRAINTS
- SET DATASKIP
- SET DEBUG FILE
- SET DEFERRED\_PREPARE
- SET DESCRIPTOR
- SET ENCRYPTION
- SET ENVIRONMENT
- SET EXPLAIN
- SET INDEXES

- SET ISOLATION
- SET LOCK MODE
- SET LOG
- SET OPTIMIZATION
- SET PDQPRIORITY
- SET ROLE
- SET STATEMENT CACHE
- SET TABLE
- SET TRANSACTION
- SET TRIGGERS

The following examples show the incorrect and correct use of a SET LOCK MODE statement inside an ON EXCEPTION statement.

The following ON EXCEPTION statement returns an error because the SET LOCK MODE statement is not enclosed in a BEGIN ... END statement block:

```
ON EXCEPTION IN (-107)
  SET LOCK MODE TO WAIT; -- error, value expected, not 'lock'
END EXCEPTION;
```

The following ON EXCEPTION statement executes successfully because the SET LOCK MODE statement is enclosed in a BEGIN ... END statement block:

```
ON EXCEPTION IN (-107)
  BEGIN
    SET LOCK MODE TO WAIT; -- ok
  END
END EXCEPTION;
```

## Jar Name

Use the Jar Name segment to specify the name of a jar ID. Use this segment whenever you see a reference to Jar Name in a syntax diagram.

### Syntax

Jar Name

*database.*

*package.*

*jar\_id*

| Element         | Description   | Restrictions  | Syntax                                     |
|-----------------|---|---|--|
| <i>database</i> | Database in which to install or access <i>jar_id</i> . Default is the current database. | Fully qualified <i>database.package.jar_id</i> identifier must not exceed 255 bytes | <a href="#">Database Name on page 1449</a> |

| Element        | Description   | Restrictions                               | Syntax                                  |
|----------------|---|--|---|
| <i>jar_id</i>  | The <b>.jar</b> file that contains the Java™ class to be accessed | File must exist in <i>database.package</i> | <a href="#">Identifier on page 1456</a> |
| <i>package</i> | Name of the package   | Package must exist in <i>database</i>      | <a href="#">Identifier on page 1456</a> |

If a jar name is specified as a character string argument to the **sqlj.install\_jar**, **sqlj.replace\_jar**, or **sqlj.remove\_jar** procedures, then any identifiers in the jar name that are delimited identifiers will include the surrounding double quotation mark characters. For descriptions of these procedures, see related concept SQLJ Driver Built-In Procedures.

Before you can access a *jar\_id* in any way (including its use in a CREATE FUNCTION or CREATE PROCEDURE statement), it must be defined in the current database with the **install\_jar()** procedure. For more information, see [EXECUTE PROCEDURE statement on page 557](#).

## Optimizer Directives

The Optimizer Directives segment specifies keywords that you can use to partially or fully specify the query plan of the optimizer. Use this segment whenever you see a reference to Optimizer Directives in a syntax diagram.

## Syntax

### Optimizer Directives

```
-- +
{ +
/* +
,
Access-Method Directives 676
Join-Order Directive 677
Join-Method Directives 678
Star-Join Directives 681
Optimization-Goal Directives 679
Explain-Mode Directives 680
Statement cache directive 682
}
*/
```

## Usage

Use one or more optimizer directives to partially or fully specify the query plan of the optimizer. The scope of the directive is the current query only.

Directives are enabled by default. To obtain information about how specified directives are processed, view the output of the SET EXPLAIN statement. To disable directives, set the **IFX\_DIRECTIVES** environment variable to 0, or set the DIRECTIVES parameter in the ONCONFIG file to 0.

The syntax diagram above is simplified, and does not show that the closing comment indicator must follow the same comment style as the opening comment indicator. For more information, see [Optimizer Directives as Comments on page 1473](#).

---

## Optimizer Directives as Comments

Optimizer directives require valid comment indicators as delimiters.

The closing delimiter you use depends on the opening delimiter:

- If `{` is the opening delimiter, you must use `}` as the closing delimiter.
- If `/*` are the opening delimiters, you must use `*/` as the closing delimiters.
- If `--` are the opening delimiters, then no closing delimiter is needed.

An optimizer directive or a list of optimizer directives immediately follows the DELETE, SELECT, or UPDATE keyword in the form of a comment. After the comment symbol, the first character in an optimizer directive is always a plus (+) sign. No blank space or other white-space character is allowed between the comment indicator and the plus sign.

You can use any of the following comment indicators:

- A double hyphen (--) delimiter

The double hyphen needs no closing symbol because it specifies only the remainder of the current line as comment. When you use this style, include the optimizer directive on only the current line.

- Braces ( {... } ) delimiters

The comment extends from the left brace ( { ) until the next right ( } ) brace; this can be in the same line or in some subsequent line.

- C-language style slash and asterisk ( /\* . . . \*/ ) delimiters

The comment extends from the initial slash-asterisk ( /\* ) pair until the next asterisk-slash ( \*/ ) characters in the same line or in some subsequent line.

In Informix® ESQL/C, the **-keepcomment** command option to the **esql** compiler must be specified when you use C-style comments.

For additional information, see [How to Enter SQL Comments on page 3](#).

If you specify multiple directives in the same query, you must separate them with a blank space, a comma, or by any character that you choose. It is recommended that you separate successive directives with a comma.

If the query declares an alias for a table, use the alias (rather than the actual table name) in the optimizer directive specification. Because system-generated index names begin with a blank character, use quotation marks to delimit such names.

Syntax errors in an optimizer directive do not cause a valid query to fail. You can use the SET EXPLAIN statement to obtain information related to such errors.

In distributed queries, optimizer directives can reference objects in other databases of the same server instance by using the *database:table* or *database:owner.table* notation to qualify the name of a table in another database of the local database server.

## Restrictions on Optimizer Directives

You can specify optimizer directives for any query in a DELETE, SELECT, or UPDATE statement, unless it includes any of the following syntax elements:

- A query accessing a table in a database of a remote database server instance
- In Informix® ESQL/C, a statement with the WHERE CURRENT OF *cursor* clause

For queries that use ANSI/ISO-compliant syntax to specify a join, the query optimizer does not follow some directives:

- The join-method directives (USE\_NL, AVOID\_NL, USE\_HASH, AVOID\_HASH, /BUILD, and /PROBE) are ignored, except in cases where the optimizer rewrites the query so that it is no longer uses the ANSI/ISO syntax.
- The join-order directive (ORDERED) is ignored in ANSI-compliant joined queries that specify the RIGHT OUTER JOIN or FULL OUTER JOIN keywords.

## Access-Method Directives

Use the access-method directives to specify the manner in which the optimizer should search the tables.

Table Reference

*alias synonym table*

| Element         | Description  | Restrictions  | Syntax                                  |
|-----------------|--|---|---|
| <i>alias</i>    | Temporary alternative table name declared in the FROM clause | If an <i>alias</i> is declared, it must be used (rather than <i>table</i> or <i>synonym</i> ) | <a href="#">Identifier on page 1456</a> |
| <i>comments</i> | Optional text that documents the directive                   | Must be outside the parentheses but inside the comment symbols                                | Character string                        |

| Element               | Description   | Restrictions  | Syntax                                  |
|-----------------------|---|---|---|
| <i>index</i>          | Index for which to specify the directive                  | Must exist. With AVOID_INDEX, AVOID_INDEX_SJ, and INDEX_SJ, at least one <i>index</i> is required | <a href="#">Identifier on page 1456</a> |
| <i>synonym, table</i> | Name or synonym of a table to which the directive applies | Synonym and the table to which it points must exist   | <a href="#">Identifier on page 1456</a> |

Use commas or blank spaces to separate elements within the parentheses.

The following table describes each of the access-method directives and indicates how it affects the query plan of the optimizer.

| Keywords                 | Effect  | Optimizer Action   |
|--------------------------|---|--|
| AVOID_FULL               | No full-table scan on the listed table                                | The optimizer considers the various indexes it can scan. If no index exists, the optimizer performs a full-table scan.   |
| AVOID_INDEX              | Does not use any of the specified indexes                             | The optimizer considers the remaining indexes and a full-table scan. If all indexes for a table are specified, optimizer uses a full-table scan to access the table.                     |
| AVOID_INDEX_SJ           | Does not use an index self-join path for the specified indexes        | The optimizer does not consider the specified index for scanning the table in an index self-join path.   |
| AVOID_MULTI_INDEX        | Does not use a multi-index scan path for the specified table          | The optimizer does not consider a multi-index scan path for the specified table.   |
| FULL                     | Performs a full-table scan  | Even if an index exists on a column, the optimizer uses a full-table scan to access the table.   |
| INDEX                    | Uses the index specified to access the table                          | If more than one index is specified, the optimizer chooses the index that yields the least cost. If no indexes are specified, then all the available indexes are considered.             |
| INDEX_ALL or MULTI_INDEX | Access the table using the specified indexes (Multi-index scan)       | These keywords are synonyms. For usage information, see "Multi-index scans" below.   |
| INDEX_SJ                 | Use the specified index to scan the table in an index self-join path. | The optimizer is forced to scan the table using an index self-join path with the specified index (or to choose the least costly index in a list of indexes for an index self-join path). |

Both the `AVOID_FULL` and `INDEX` keywords specify that the optimizer should avoid a full scan of a table. It is recommended, however, that you use the `AVOID_FULL` keyword to specify the intent to avoid a full scan on the table.

The `AVOID_MULTI_INDEX` directive does not accept a list of indexes as its argument. This is because the `AVOID_INDEX` directive also prevents the specified index from being used in a multi-index scan execution path.

## Multi-index scans

Up to sixteen (16) indexes can be defined on a table. A search path based on an access method that uses more than one index on the same table is called a *multi-index scan*. The `MULTI_INDEX` or `INDEX_ALL` directive forces the query optimizer to consider a multi-index scan to search the specified table for qualifying rows. The argument list for the `MULTI_INDEX` or `INDEX_ALL` directive has these semantics:

- If you specify a table as the only argument to the directive, the optimizer considers all of the available indexes on that table, and uses all of them (or a subset) when it searches the table for qualifying rows.
- If you specify a table and only a single index, the optimizer considers using only that index to scan the table.
- If you specify a table and more than one index, the optimizer considers a search path that uses all of the specified indexes.

## Multi-index scan with skip-scan access methods

A multi-index scan path accesses a table by a *skip-scan* access method, using a sorted list of ROWIDs. The sorted list is typically generated from a multi-index scan access method, using all of the indexes that the `INDEX_ALL` or `MULTI_INDEX` directive specifies.

For example, if the query predicates specify `col1 <= 10` and `col2 BETWEEN 15 AND 25`, then the execution plan can use two indexes: the first index on `col1`, and the second index on `col2`. Each index scan returns all ROWIDs that satisfy the search condition for the respective index. The logical intersection of the two lists of ROWIDs includes only the rows that satisfy both search conditions. The database server then sorts the combined ROWID list, and uses this sorted list to scan the table for the result set of the query.

If the query includes predicates on more than two indexed columns, the list of ROWIDs that each index scan returns must be combined to produce a sorted ROWID list of all the qualifying rows.

Because each ROWID represents the physical location of a row (on which page and in which slot), the execution path simply accesses that physical location to retrieve the row. As the term "skip-scan" suggests, there are typically gaps from one ROWID to the next in the sorted list, so that the database server "skips" from one qualifying row to the next qualifying row of the result set.

The list of sorted ROWIDs can be generated from multiple index scans, as described above, or from a single index scan. In the case of a single index, the skip-scan execution path takes these actions:

1. The single index scan creates an unsorted list of the ROWIDs of all qualifying rows.
2. This unsorted list is sorted by ROWID value.
3. The database server then retrieves the qualifying rows in the order of their ROWIDs.

A skip-scan access method resembles a sequential scan, but can sometimes be more efficient. A sequential scan retrieves every row in the table, but a skip-scan only retrieves the rows that have qualifying ROWIDs.

## Restrictions on multi-index scan paths for query execution

The transaction isolation level affects whether the `MULTI_INDEX` or `INDEX_ALL` directive can force a multi-index scan execution path, which is not available while the isolation level is Cursor Stability, or is Committed Read with the `LAST COMMITTED` option. (This directive is supported, however, in the Dirty Read and Repeatable Read isolation levels, and in Committed Read without the `LAST COMMITTED` option.)

The following additional restrictions apply to multi-index scan access paths:

- The indexes must be B-tree indexes. These can be attached or detached indexes.
- These directives are ignored for R-tree indexes, functional indexes, and indexes based on the Virtual Index Interface (VII).
- The table cannot be a remote table, a pseudo-table, a system catalog table, an external table, or a hierarchical table.
- A multi-index scan cannot support join predicates as index filters in the underlying index scans.
- A multi-index scan ignores all columns of a composite index except the leading column.
- DML statements that perform cascade deletes or declare statement local variables (SLVs) cannot use a multi-index scan.
- Update queries that activate a `FOR EACH ROW` triggered action cannot use a multi-index scan.
- In ANSI-compliant databases, the `MULTI_INDEX` or `INDEX_ALL` directive is not followed for a `SELECT` statement that has no `ORDER BY` clause, no `GROUP BY` clause, and no `FOR READ ONLY` clause, if the `FROM` clause specifies only a single table. (In this special case, the query has implicit cursor behavior that conflicts with a multi-index scan access path.)

## Combinations of access method directives

In general, you can specify only one access-method directive per table. Only the following combinations of access-method directives are valid for the same table in the same query:

- `INDEX, AVOID_INDEX_SJ`
- `AVOID_FULL, AVOID_INDEX`
- `AVOID_FULL, AVOID_INDEX_SJ`
- `AVOID_INDEX, AVOID_INDEX_SJ`
- `AVOID_FULL, AVOID_INDEX, AVOID_INDEX_SJ`
- `AVOID_FULL, AVOID_MULTI_INDEX`
- `AVOID_INDEX, AVOID_MULTI_INDEX`
- `AVOID_INDEX_SJ, AVOID_MULTI_INDEX`
- `AVOID_FULL, AVOID_INDEX_SJ, AVOID_MULTI_INDEX`
- `AVOID_INDEX, AVOID_INDEX_SJ, AVOID_MULTI_INDEX`

When you specify both the `AVOID_FULL` and `AVOID_INDEX` access-method directives, the optimizer avoids performing a full scan of the table and it avoids using the specified index or indexes. This combination of negative directives allows the optimizer to use indexes that are created after the access-method directives are specified.

Because the optimizer automatically considers the index self-join path if you specify the `INDEX` or `AVOID_FULL` directive, use the `INDEX_SJ` directive only to force an index self-join path using the specified index (or choosing the least costly index in

a comma-separated list of indexes). The INDEX\_SJ directive can improve performance when a multicolumn index includes columns that provide only low selectivity as index key filters.

Specifying the INDEX\_SJ directive circumvents the usual optimizer requirement for data distribution statistics on the lead keys of the index. This directive causes the optimizer to consider an index self-join path, even if data distribution statistics are not available for the leading index key columns. In this case, the optimizer only includes the minimum number of index key columns as lead keys to satisfy the directive.

For example, if an index is defined on columns **c1**, **c2**, **c3**, **c4**, and the query specifies filters on all four of these columns but no data distributions are available on any column, then specifying INDEX\_SJ on this index will result in column **c1** being used as the lead key in an index self-join path. If you want the optimizer to use an index but not to consider the index self-join path, then you must specify an INDEX or AVOID\_FULL directive to choose the index, and you must also specify an AVOID\_INDEX\_SJ directive to prevent the optimizer from considering any other index self-join path.

If AVOID\_INDEX\_SJ is used together with the INDEX directive, either as an explicit INDEX directive or as the equivalent AVOID\_FULL and AVOID\_INDEX combination, the indexes specified in the AVOID\_INDEX\_SJ directive must be a subset of the indexes specified in the INDEX directive. For more information about the effects of the INDEX\_SJ and AVOID\_INDEX\_SJ directives, see the chapter of the *Informix® Performance Guide* that describes optimizer directives.

Specifying the MULTI\_INDEX or INDEX\_ALL directive circumvents the usual optimizer requirement for statistics on the specified table. The optimizer normally requires at least low level statistics on the table before considering multi-index scan path on the table.

### Examples of Access Method Directives

Suppose that you have a table named **emp** that contains the columns **emp\_no**, **dept\_no**, and **job\_no**, and for which the following indexes **ids\_dept\_no** index is defined on the **dept\_no** column, and the **idx\_job\_no** index is defined on the **job\_no** column. When you perform a SELECT that includes the **emp** table in the FROM clause, you might direct the optimizer to access the table in one of the following ways:

- Example using a positive directive:

```
SELECT {+INDEX(emp idx_dept_no)} ...
```

In the example above, the access-method directive forces the optimizer to consider an execution path that scans the **idx\_dept\_no** index on the **dept\_no** column.

In the following example the access-method directive forces the optimizer to consider using a multi-index scan, based on the combined results of scanning both the **idx\_dept\_no** index on the **dept\_no** column and the **idx\_job\_no** index on the **job\_no** column.

```
SELECT {+MULTI_INDEX(emp idx_dept_no ids_job_no)} ...
```

- Example using negative directives:

```
SELECT {+AVOID_INDEX(emp idx_loc_no, idx_job_no), AVOID_FULL(emp)} ...
```

This example includes multiple access-method directives. These directives force a scan of the **idx\_dept\_no** index on the **dept\_no** column by instructing the optimizer not to scan the **idx\_loc\_no** and **idx\_job\_no** indexes, and not to perform a full scan of the **emp** table. If a new **idx\_emp\_no** index, however, is created for table **emp**, these directives do not prevent the optimizer from considering it.

Note also that the term *negative directive* refers to the string "AVOID\_" in an access method directive, and has nothing to do with the + symbol following the comment indicator that begins every optimizer directive.

## Join-Order Directive

Use the ORDERED join-order directive to force the optimizer to join tables or views in the order in which they are referenced in the FROM clause of the query.

Join-Order Directive

### ORDERED

*comments*

| Element         | Description                    | Restrictions                        | Syntax           |
|-----------------|--------------------------------|-------------------------------------|------------------|
| <i>comments</i> | Text to document the directive | Must appear between comment symbols | Character string |

For example, the following query forces the database server to join the **dept** and **job** tables and then join the result with the **emp** table:

```
SELECT --+ ORDERED
  name, title, salary, dname
FROM dept, job, emp WHERE title = 'clerk' AND loc = 'Palo Alto'
AND emp.dno = dept.dno
AND emp.job= job.job;
```

Because no predicates occur between the **dept** table and the **job** table, this query forces the database server to construct a Cartesian product.

When your query involves a view, the placement of the ORDERED join-order directive determines whether you are specifying a partial- or total-join order.

- Specifying partial-join order when you create a view

If you use the ORDERED directive when you create a view, the base tables are joined contiguously in the order of the view definition.

For all subsequent queries on the view, the database server joins the base tables contiguously in the order specified in the view definition. When used in a view, the ORDERED directive does not affect the join order of other tables named in the FROM clause in a query.

- Specifying total-join order when you query a view

When you specify the ORDERED join-order directive in a query that uses a view, all tables are joined in the order specified, even those tables that form views. If a view is included in the query, the base tables are joined contiguously in the order of the view definition. For examples of ORDERED with views, refer to your *Informix® Performance Guide*.

Because of ordering requirements for OUTER joins, in ANSI-compliant joined queries that specify the RIGHT OUTER JOIN or FULL OUTER JOIN keywords, the ORDERED join-order directive is ignored, but it is listed under *Directives Not Followed* in the explain output file.

(
, Table Reference683
```

### AVOID\_HASH USE\_HASH

```
(
,
Table Reference683
```

### /BUILD /PROBE

```
)
comments
```

| Element         | Description                     | Restrictions                        | Syntax           |
|-----------------|---------------------------------|-------------------------------------|------------------|
| <i>comments</i> | Text to documents the directive | Must appear between comment symbols | Character string |

Use commas or blank spaces to separate the elements within the parentheses.

The following table describes each of the join-method directives.

#### Keyword

#### Effect

683. See [Access-Method Directives on page 1475](#)

**USE\_NL**

Uses the specified tables as the inner table in a nested-loop join

If  $n$  tables are specified in the FROM clause, then at most  $(n-1)$  tables can be specified in the USE\_NL join-method directive.

**USE\_HASH**

Uses a hash join to access the specified table

You can also choose whether the table will be used to create the hash table or to probe the hash table.

**AVOID\_NL**

Does not use the specified table as inner table in a nested loop join

A table listed with this directive can still participate in a nested loop join as the outer table.

**AVOID\_HASH**

Does not access the specified table using a hash join

You can optionally use a hash join, but impose restrictions on the role of the table within the hash join.

A join-method directive takes precedence over the join method forced by the OPTCOMPIND configuration parameter.

When you specify the USE\_HASH or AVOID\_HASH directives (to use or avoid a hash join, respectively), you can also specify the role of each table:

- /BUILD

With the USE\_HASH directive, this keyword indicates that the specified table be used to construct a hash table. With the AVOID\_HASH directive, this keyword indicates that the specified table *not* be used to construct a hash table.

- /PROBE

With the USE\_HASH directive, this keyword indicates that the specified table be used to probe the hash table. With the AVOID\_HASH directive, this keyword indicates that the specified table *not* be used to probe the hash table. You can specify multiple probe tables as long as there is at least one table for which you do not specify PROBE.

For the optimizer to find an efficient join query plan, you must at least run UPDATE STATISTICS LOW for every table that is involved in the join, so as to provide appropriate cost estimates. Otherwise, the optimizer might choose to broadcast the entire table to all instances, even if the table is large.

If neither the /BUILD nor the /PROBE keyword is specified, the optimizer uses cost estimates to determine the role of the table.

In this example, the USE\_HASH directive forces the optimizer to construct a hash table on the **dept** table and consider only the hash table to join **dept** with the other tables. Because no other directives are specified, the optimizer can choose the least expensive join methods for the other joins in the query.

```
SELECT /*+ USE_HASH (dept /BUILD)
  The optimizer must use dept to construct a hash table */
name, title, salary, dname
```

```
FROM emp, dept, job WHERE loc = 'Phoenix'
      AND emp.dno = dept.dno AND emp.job = job.job;
```

Join-method optimizer directives that you specify for an ANSI-compliant joined query are ignored, but they are listed under *Directives Not Followed* in the explain output file.

## Star-Join Directives

Use the star-join directives to specify the manner in which the optimizer should join tables that have a star schema.

Star-Join Directives

**AVOID\_FACT**(

, Table Reference

)

**FACT**( Table Reference)

**STAR\_JOIN AVOID\_STAR\_JOIN**

*comments*

Table Reference

*alias synonym table*

| Element               | Description  | Restrictions  | Syntax                                  |
|-----------------------|--|---|---|
| <i>alias</i>          | Temporary alternative table name declared in the FROM clause | If an <i>alias</i> is declared, it must be used (rather than <i>table</i> or <i>synonym</i> ) | <a href="#">Identifier on page 1456</a> |
| <i>comments</i>       | Optional text that documents the directive                   | Must be outside the parentheses but inside the comment symbols                                | Character string                        |
| <i>synonym, table</i> | Name or synonym of a table to which the directive applies    | Synonym and the table to which it points must exist   | <a href="#">Identifier on page 1456</a> |

In AVOID\_FACT directives that specify more than one table, use a comma or blank space to separate consecutive elements within the parentheses.

The following table describes each of the star-join directives and indicates how it affects the query plan of the optimizer.

| Keywords        | Effect   | Optimizer Action   |
|-----------------|--|--|
| AVOID_FACT      | At least one table must be specified. Do not use the table (or any table in the list of tables) as a fact table in star-join optimization. | The optimizer does not consider a star-join execution plan that treats the specified table (or any of the tables in the list of tables) as a fact table. |
| AVOID_STAR_JOIN | The optimizer does not consider a star-join execution plan.  | The optimizer chooses a query execution plan that is not a star-join plan.   |
| FACT            | Exactly one table must be specified. Only consider the specified table as a fact table in the star-join execution plan.                    | These optimizer considers a query plan in which the specified table is a fact table in a star-join execution plan.                                       |
| STAR_JOIN       | Favor a star-join plan, if one is possible.  | The optimizer favors a star-join execution plan, if available.   |

The star-join directives require that the parallel database query feature (PDQ) be enabled. Star join query optimization is disabled when PDQ is off.

The star-join directives require that all tables in the query have at least low level statistics. If table statistics are not available for any table in the query, star-join query optimization is disabled.

The SET OPTIMIZATION ENVIRONMENT STAR\_JOIN DISABLED statement of SQL disables star-join optimization in the current session. (For additional information about optimization environment settings, see [ENVIRONMENT Options on page 989](#).)

Specifying the FACT directive alone does not automatically favor a star-join execution plan. You can direct the optimizer to prefer a star-join execution plan with a specific fact table by specifying a combination of a STAR\_JOIN directive and a FACT directive.

You can view the star join optimization path of a query in the output file of the SET EXPLAIN statement, or by using Data Studio to obtain Visual Explain output.

In cluster environments, the star-join optimizer directives are valid on these types of secondary servers:

- Shared disk secondary servers (SDS)
- Remote standalone secondary servers (RSS)
- High-availability data replication secondary servers (HDR).

### Restrictions on star-join directives

The following restrictions apply to queries that attempt to join tables that have star-schema dependencies:

- The parallel database query (PDQ) feature must be enabled for star-join directives to be valid.
- All tables in the query must have at least low level statistics.

- Star-join directives do not support joins of more than one fact table.
- Star-join directives are not valid while the transaction isolation level is Committed Read Last Committed or Cursor Stability. (All other transaction isolation levels are supported.)

## Optimization-Goal Directives

Use optimization-goal directives to specify the measure that is used to determine the performance of a query result.

Optimization-Goal Directives

### **ALL\_ROWS FIRST\_ROWS**

*comments*

| Element         | Description                    | Restrictions                        | Syntax           |
|-----------------|--------------------------------|-------------------------------------|------------------|
| <i>comments</i> | Text documenting the directive | Must appear between comment symbols | Character string |

The two optimization-goal directives are:

- **FIRST\_ROWS**

This tells the optimizer to choose a plan that optimizes the process of finding only the first screenful of rows that satisfies the query. Use this option to decrease initial response time for queries that use an interactive mode or that require the return of only a few rows.

- **ALL\_ROWS**

This directive tells the optimizer to choose a plan that optimizes the process of finding all rows that satisfy the query.

This form of optimization is the default.

An optimization-goal directive takes precedence over the **OPT\_GOAL** environment variable setting and over the **OPT\_GOAL** configuration parameter.

For information about how to set the optimization goal for an entire session, see the **SET OPTIMIZATION** statement.

You cannot use an optimization-goal directive in the following contexts:

- In a view definition
- In a subquery

The following query returns the names of the employees who earned the top fifty bonuses. The optimization-goal directive directs the optimizer to return the first screenful of rows as fast as possible.

```
SELECT {+FIRST_ROWS
Return the first screenful of rows as fast as possible}
LIMIT 50 fname, lname FROM employees ORDER BY bonus DESC;
```

## Explain-Mode Directives

Use the explain-mode directives to test and debug query plans and to print information about the query plan to the explain output file.

Explain-Mode Directives

### **EXPLAIN**

**, AVOID\_EXECUTE**

*comments*

| Element         | Description                    | Restrictions                        | Syntax           |
|-----------------|--------------------------------|-------------------------------------|------------------|
| <i>comments</i> | Text documenting the directive | Must appear between comment symbols | Character string |

The following table lists the effect of each explain-mode directive.

#### **Keyword**

#### **Effect**

#### **EXPLAIN**

Turns SET EXPLAIN ON for the specified query

#### **AVOID\_EXECUTE**

Prevents the data manipulation statement from executing; instead, the query plan is printed to the explain output file

The EXPLAIN directive is primarily useful for testing and debugging query plans. It is redundant when SET EXPLAIN ON is already in effect. It is not valid in a view definition or in a subquery.

The next query executes and prints the query plan to the explain output file:

```
SELECT {+EXPLAIN}
  c.customer_num, c.lname, o.order_date
FROM customer c, orders o WHERE c.customer_num = o.customer_num;
```

The AVOID\_EXECUTE directive prevents execution of a query on either the local or remote site, if a remote table is part of the query. This directive does not prevent nonvariant functions in a query from being evaluated.

The next query does returns no data, but writes its query plan to the explain output file:

```
SELECT {+EXPLAIN, AVOID_EXECUTE}  c.customer_num, c.lname, o.order_date
FROM customer c, orders o WHERE c.customer_num = o.customer_num;
```

You must use both the EXPLAIN and AVOID\_EXECUTE directives to see the query plan of the optimizer (in the explain output file) without executing the query. The comma ( , ) separating these two directives is optional.

If you omit the EXPLAIN directive when you specify the AVOID\_EXECUTE directive, no error is issued, but no query plan is written to the explain output file and no DML statement is executed.

You cannot use the explain-mode directives in the following contexts:

- In a view definition
- In a trigger
- In a subquery

They are valid, however, in a SELECT statement within an INSERT statement.

The `AVOID_STMT_CACHE` directive is useful for those statements whose query plans can change significantly depending on the values of the placeholders that are passed to the database server when the statements are run. Using a cached query plan for those sorts of statements might result in poor performance.

For example, the following statement is not stored in the statement cache:

```
SELECT {+AVOID_STMT_CACHE}
  c.customer_num, c.lname, o.order_date
FROM customer c, order o
WHERE c.customer_num = o.customer_num;
```

## External Directives

You can use the `SAVE EXTERNAL DIRECTIVES` statement to store optimizer directives in the **sysdirectives** table of the system catalog. Informix® applies these external directives automatically to subsequent queries and subqueries that match a specified SELECT statement.

The EXT\_DIRECTIVES configuration parameter and the **IFX\_EXTDIRECTIVES** environment variable can be set to control whether external directives are enabled or disabled for the database server instance or for the session. Setting either of these to zero disables external directives; setting both to 1 enables external directives.

You can also use the EXTDIRECTIVES option of the SET ENVIRONMENT statement to enable or disable external directives during a session. For more information, see [Enabling or disabling external directives for a session on page 763](#).

## Owner name

The owner name specifies the owner of a database object. Use this segment whenever you see a reference to Owner Name in a syntax diagram.

### Syntax

Owner Name

"owner" owner

<sup>684</sup>owner'

| Element | Description                                       | Restrictions               | Syntax  |
|---------|---|----------------------------|---|
| owner   | User name of the owner of an object in a database | Maximum length is 32 bytes | Must conform to the rules of your operating system. |

### Usage

In an ANSI-compliant database, you must specify the *owner* of any database object that you do not own. In reference to the owner of database objects, the ANSI/ISO synonym for owner name is *authorization identifier*. (In reference to schema objects, however, the ANSI/ISO term for what the Informix® documentation calls an *owner name* is *schema name*.)

In databases that are not ANSI-compliant, the *owner* name is optional. You do not need to specify *owner* when you create database objects or use data access statements. If you do not specify *owner* when you create a database object, the database server assigns your login name as the owner of the object, in most cases. For exceptions to this rule, see [Ownership of Created Database Objects on page 251](#) in the CREATE FUNCTION statement description, and [Ownership of Created Database Objects on page 301](#) in the CREATE PROCEDURE statement description. When a DDL statement in an owner-privileged UDR creates a new database object, the owner of the routine (rather than the user who executes it, if that user is not the owner of the routine) becomes the owner of the new database object.

If you specify *owner* in data-access statements, the database server checks it for correctness. Without quotation marks, *owner* is case insensitive. The following four queries all can access data from the table **kaths.tab1**:

684. Informix® extension

```
SELECT * FROM tab1;
SELECT * FROM kaths.tab1;
SELECT * FROM KATHS.tab1;
SELECT * FROM KathS.tab1;
```

In an ANSI-compliant database, only the owner of the table, user **kaths**, can issue the first of these example queries, which specifies an unqualified table name, but any user who holds the Select privilege on **tab1** can issue that query in a database that is not ANSI-compliant. For more information about owner names in ANSI-compliant databases, see [ANSI-Compliant Database Restrictions and Case Sensitivity on page 1490](#).

A *role* that the CREATE ROLE statement declares is an authorization identifier, and is therefore subject to the syntax restrictions on owner names, but a role cannot be the owner of a database object. Similarly, the keyword PUBLIC, which specifies the group of all users, cannot be the owner of a database object, except in the special cases of the **sysdbopen()** and **sysdbclose()** procedures. For more information about these built-in session configuration UDRs, see Session Configuration Procedures.

## Using Quotation Marks

Within quotation marks, *owner* is case sensitive. Quotation marks instruct the database server to read or store the name exactly as typed when you create or access a database object. For example, suppose that you have a table whose owner is **Sam**. You can use either one of the following two statements to access data in the table:

```
SELECT * FROM table1;
SELECT * FROM 'Sam'.table1;
```

The first query succeeds because the owner name is not required. The second query succeeds because the specified owner name matches the owner name as it is stored in the database.

## Referencing Tables Owned by User informix

If you use the owner name as one of the selection criteria to access database object information from one of the system catalog tables, the owner name is case sensitive. To preserve lettercase, you must enclose *owner* in single or double quotation marks, and you must type the owner name exactly as it is stored in the system catalog table. Of the following two examples, only the second successfully accesses information on the table **Kaths.table1**.

```
SELECT * FROM systables WHERE tabname = 'tab1' AND owner = 'kaths';
SELECT * FROM systables WHERE tabname = 'tab1' AND owner = 'Kaths';
```

User **informix** is the owner of the system catalog tables, and in an ANSI-compliant database you must specify **informix** as a qualifier when SQL statements reference system catalog tables, unless you are user **informix**:

```
SELECT * FROM "informix".systables WHERE tabname = 'tab1' AND owner = 'Kaths';
```

Informix® accepts any of the following notations to specify a system catalog table of an ANSI-compliant database:

- `"informix".system_table`
- `informix.system_table`
- `'informix'.system_table`

Of these three formats, however, only the first, where the *owner* is specified as a delimited identifier, is directly interoperable with most other database servers. For the format with no delimiters, the ANSI/ISO standard for SQL upshifts the lowercase letters to `INFORMIX`, and the same standard does not support single ( ' ) quotation marks as valid delimiters for owner names or for schema names.

In contrast, Informix® treats the name **informix** as a special case, and preserves lowercase letters when **informix** is specified, with or without delimiters, whether or not the database is ANSI-compliant. To write SQL code that is portable to non-Informix® database servers, however, you should always delimit the owner names of database objects between double ( " ) quotation marks.

The following SQL examples use undelimited owner names:

```
CREATE TABLE informix.t1(i SERIAL NOT NULL);
CREATE TABLE someone.t1(i SERIAL NOT NULL);
```

If these statements execute successfully, the first table has `informix` registered in **systables** as the owner, and the second has `SOMEONE` registered as the owner. When the owner name is delimited by quotation marks in SQL statements, the specified lettercase of *owner* is preserved, but the lettercase does not matter when the owner name is undelimited, because Informix® upshifts most undelimited owner names, but downshifts the undelimited **informix** (or **INFORMIX**) owner name to `informix`.

For example, suppose that after the previous two CREATE TABLE statements execute successfully, user **informix** issues the following statement:

```
CREATE TABLE INFORMIX.t1(i SERIAL NOT NULL);
```

This statement fails, because the combination of *owner* name and *table* name is not unique, if the previously registered table **t1** that is owned by **informix** already exists in the database.

**Tip:** The `USER` operator returns the login name of the current user exactly as it is stored on the system. If the owner name is stored differently from the login name (for example, a mixed-case owner name and an all lowercase login name), the `owner = USER` syntax fails.

## ANSI-Compliant Database Restrictions and Case Sensitivity

The following table describes how the database server reads and stores *owner* when you create, rename, or access a database object.

| Owner Name Specification          | What the ANSI-Compliant Database Server Does   |
|-----------------------------------|--|
| Omitted                           | Reads or stores <i>owner</i> exactly as the login name is stored in the system, but returns an error if the user is not the <i>owner</i> . |
| Specified without quotation marks | Reads or stores <i>owner</i> in uppercase letters  |

| Owner Name Specification         | What the ANSI-Compliant Database Server Does  |
|----------------------------------|---|
| Enclosed between quotation marks | Reads or stores <i>owner</i> exactly as entered. See also <a href="#">Using Quotation Marks on page 1489</a> and <a href="#">Referencing Tables Owned by User informix on page 1489</a> . |

If you specify the owner name when you create or rename a database object in an ANSI-compliant database, you must include the owner name in data access statements. You must include the owner name when you access a database object that you do not own.

Because the database server automatically shifts *owner* to uppercase letters if not between quotation marks, case-sensitive errors can cause queries to fail. For example, if you are user **nancy** and you use the following statement, the resulting view has the name **nancy.njcust**:

```
CREATE VIEW 'nancy'.njcust AS
SELECT fname, lname FROM customer WHERE state = 'NJ';
```

The following SELECT statement fails because it tries to match the name **NANCY.njcust** to the actual owner and table name of **nancy.njcust**:

```
SELECT * FROM nancy.njcust;
```

In a distributed query, if the owner name is not between quotation marks, the remote database follows the lettercase convention of the local database. If the local database is ANSI-compliant, then the remote database processes the owner name in *uppercase*. If the local database is not ANSI compliant, then the remote database processes the owner name in *lowercase*.

**Tip:** When you use the owner name as one of the selection criteria in a query (for example, `WHERE owner = 'kaths'`), make sure that the quoted string matches the owner name exactly as it is stored in the database. If the database server cannot find the database object or database, you might need to modify the query so that the quoted string uses uppercase letters (for example, `WHERE owner = 'KATHS'`).

Because owner name is an authorization identifier, rather than an SQL identifier, you can enclose *owner* between single-quotation marks ( `'` ) in SQL statements of a database where the **DELIMITED** environment variable specifies support for delimited identifiers, thereby requiring double-quotation marks ( `"` ) around SQL identifiers.

## Setting ANSIOWNER for an ANSI-Compliant Database

### About this task

The default behavior of an ANSI-compliant database is to replace any lowercase letters with uppercase letters in any *owner* specification that is not enclosed in quotation marks. You can prevent this by setting the **ANSIOWNER** environment variable to 1 before the database server is initialized. This preserves whatever lettercase you use when you specify the *owner* string without quotation marks.

## Default Owner Names

If you create a database object without explicitly specifying an owner name in a database that is not ANSI-compliant, your authorization identifier (as the default owner of the object) is stored in the system catalog of the database as if you had specified your authorization identifier within quotation marks (that is, preserving the lettercase).

If you create a database object without explicitly specifying an owner name in a database that is ANSI-compliant, any lowercase letters in your authorization identifier (as the default owner of the object) are stored in the system catalog of the database in uppercase characters, unless the **ANSIOWNER** environment variable was set to 1 before the database server was initialized. If **ANSIOWNER** was set to 1, however, the database stores the default owner of the object as your authorization identifier, with its lettercase preserved.

## Summary of Lettercase Rules for Owner Names

To create a database object, such as a table called **mytab**, a user whose login name is **Otho** can declare the name of the new database object in any of the following ways:

1. `CREATE TABLE mytab . . .`
2. `CREATE TABLE Otho.mytab . . .`
3. `CREATE TABLE "Otho".mytab . . .`

The format in which an undelimited *owner* name (as in the second example) is stored in the **owner** column of the **systables** system catalog table is dependent on whether or not the local database is an ANSI-compliant database.

- In case 1, no *owner* name is specified. The implicit owner of the table is **Otho**, the user who created the table, and that owner name is stored in the **systables** table in the same format (**Otho**) as the user ID of the owner, independent of the ANSI-compliance status of the database.
- In case 2, an undelimited *owner* name is specified. The **systables** table stores all letters in the *owner* name in lowercase (here as **otho**) for databases that are not ANSI-compliant databases. For ANSI-compliant databases in which **ANSIOWNER** is not set to 1, **systables** table stores all *owner* name letters in uppercase (here as **OTHO**). If **ANSIOWNER** is set to 1, however, the name is stored in the same lettercase as specified in the DDL statement (here as **Otho**).
- In case 3, the delimited *owner* name is stored in the **systables** table in the same format in which it was specified (here as **Otho**), independent of the ANSI-compliance status of the database.

Note that user identifiers are case sensitive, but database object names are case insensitive. Therefore, the same user cannot own both a table **tab** and a table **TAB**.

In addition to the CREATE TABLE statement in these examples, all SQL statements and SPL statements follow these rules where a table name can be specified. For example, when using DROP TABLE, the format in which owner name appears while the statement is being processed is dependent upon the same conditions:

- whether an explicit owner name is specified.
- if an explicit owner name is specified, whether quotation marks delimit the owner name.
- if an explicit owner name is not delimited by quotation marks, whether or not the database is ANSI compliant.
- if the database is ANSI compliant, whether or not **ANSIOWNER** was set to 1 before the database was initialized.

## Purpose Options

The CREATE ACCESS\_METHOD, CREATE XADATASOURCE TYPE, and ALTER ACCESS\_METHOD statements of Informix® can specify purpose options for user-defined routines with the following syntax.

### Syntax

Purpose Options

*task = external\_routine*

*value =*

*string\_value numeric\_value*

*flag*

| Element                 | Description   | Restrictions  | Syntax  |
|-------------------------|---|---|---|
| <i>external_routine</i> | User-defined routine that performs a <i>task</i>    | Must be registered in the database  | <a href="#">Database Object Name on page 1450</a>   |
| <i>flag</i>             | Keyword indicating which feature a flag enables     | The interface specifies flag names  | <i>Flag</i> Purpose Category in the table in <a href="#">Purpose Functions, Flags, and Values on page 1495</a> .  |
| <i>numeric_value</i>    | A value of a real number                            | Must be within the range of a numeric data type                                   | <a href="#">Literal Number on page 1419</a>   |
| <i>string_value</i>     | A value that is expressed as one or more characters | Characters must be from the code set of the database                              | <a href="#">Quoted String on page 1424</a> .  |
| <i>task</i>             | Keyword that identifies a purpose function          | Keywords to which you can assign a function (whose name cannot match the keyword) | <i>Task</i> Purpose Category in the table in <a href="#">Purpose Functions, Flags, and Values on page 1495</a> .  |
| <i>value</i>            | Keyword that identifies configuration information   | Predefined configuration keywords to which you can assign values                  | <i>Value</i> Purpose Category in the table in <a href="#">Purpose Functions, Flags, and Values on page 1495</a> . |

### Usage

Informix® supports purpose options in two contexts:

- Defining or modifying primary and secondary access methods for local or remote tables, views, and indexes
- Defining access methods for XA-compliant external data sources.

---

**Related reference**[ALTER ACCESS\\_METHOD statement on page 20](#)[CREATE ACCESS\\_METHOD statement on page 193](#)[CREATE XDATASOURCE TYPE statement on page 460](#)[CREATE OPCLASS statement on page 286](#)

## Purpose Options for Access Methods

A registered access method is a set of attributes, including a name and options called *purpose options*, that you can use to accomplish the following tasks:

- Specify which functions perform data access and manipulation tasks, such as opening, reading, and closing a data source.
- Set configuration options, such as a storage-space type.
- Set flags, such as enabling rowid interpretation.

You specify purpose options when you create an access method with the CREATE ACCESS\_METHOD statement. To change the purpose options of an access method, use the ALTER ACCESS\_METHOD statement.

Each *task*, *value*, or *flag* keyword corresponds to a column name in the **sysams** system catalog table. The keywords let you set the following attributes:

- Purpose function

A *purpose-function attribute* maps the name of a user-defined function or method to a *task* keyword, such as **am\_create**, **am\_beginscan**, or **am\_getnext**. For a complete list of these keywords, see the Task category in the table in [Purpose Functions, Flags, and Values on page 1495](#). The *external\_routine* specifies the corresponding function (C) that you supply for the access method. Example setting:

```
am_create = FS_create
```

- Purpose flag

A *purpose flag* indicates whether an access method supports a given SQL statement or keyword. Example setting:

```
am_rowids
```

- Purpose value

These string, character, or numeric values provide configuration information that a flag cannot supply. Example setting:

```
am_sptype = 'X'
```

To enable a user-defined function or method as a purpose function, you must first register the C function or Java™ method that performs the appropriate tasks, using the CREATE FUNCTION statement, and then set the purpose keyword equal to

the registered function or method name. This creates a new access method. An example on page [ALTER ACCESS\\_METHOD statement on page 20](#) adds a purpose method to an existing access method.

To enable a purpose flag, specify the name without a corresponding value.

To clear a purpose-option setting in the **sysams** table, use the DROP clause of the ALTER ACCESS\_METHOD statement.

## Purpose Functions, Flags, and Values

Purpose functions, methods, and flags defined the attributes of access methods.

The following table describes the possible settings for the **sysams** columns that contain purpose functions or methods, flags, and values. The entries appear in the same order as the corresponding **sysams** columns.

**Table 32. Purpose functions, purpose flags, and purpose values**

| Keyword              | Explanation  | Category | Default                          |
|----------------------|--|----------|----------------------------------|
| <b>am_sptype</b>     | <p>A character that specifies from what type of storage space a primary or secondary-access method can access data. The <b>am_sptype</b> character can have any of the following settings:</p> <ul style="list-style-type: none"> <li>• 'X' indicates the method accesses only extspaces.</li> <li>• 'S' indicates the method accesses only sbspaces.</li> <li>• 'A' indicates the method can access extspaces and sbspaces.</li> </ul> <p>Valid only for a new access method. You cannot change or add an <b>am_sptype</b> value with ALTER ACCESS_METHOD. Do not set <b>am_sptype</b> to 'D' or attempt to store a virtual table in a dbspace.</p> | Value    | Virtual-Table Interface (C): 'A' |
| <b>am_defopclass</b> | The default operator class for a secondary-access method. The access method must exist before you can define its operator class, so you set this value in the ALTER ACCESS_METHOD statement.   | Value    | None                             |
| <b>am_keyscan</b>    | A flag that, if set, indicates that <b>am_getnext</b> returns rows of index keys for a secondary-access method. If a query selects only the columns in the index key, the database server uses the row of index keys that the secondary-access method puts in shared memory, without reading the table.  | Flag     | Not set                          |
| <b>am_unique</b>     | A flag to set if a secondary-access method checks for unique keys  | Flag     | Not set                          |
| <b>am_cluster</b>    | A flag that you set if a primary- or secondary-access method supports clustering of tables   | Flag     | Not set                          |

**Table 32. Purpose functions, purpose flags, and purpose values (continued)**

| Keyword                 | Explanation   | Category | Default |
|-------------------------|---|----------|---------|
| <b>am_rowids</b>        | A flag that you set if a primary-access method can retrieve a row from a specified address  | Flag     | Not set |
| <b>am_readwrite</b>     | A flag to set if a primary-access method supports data changes. The default setting, not set, indicates that the virtual data is read-only. For the C Virtual-Table Interface, set this flag if your application writes data, to avoid the following problems: <ul style="list-style-type: none"> <li>• An INSERT, DELETE, UPDATE, or ALTER FRAGMENT statement causes an SQL error.</li> <li>• Function <b>am_insert</b>, <b>am_delete</b>, or <b>am_update</b> is not run.</li> </ul>  | Flag     | Not set |
| <b>am_parallel</b>      | A flag that the database server sets to indicate which purpose functions or methods can run in parallel in a primary or secondary-access method. If set, the hexadecimal <b>am_parallel</b> bitmap contains one or more of the following bit settings: <ul style="list-style-type: none"> <li>• The 1 bit is set for parallelizable scan.</li> <li>• The 2 bit is set for parallelizable delete.</li> <li>• The 4 bit is set for parallelizable update.</li> <li>• The 8 bit is set for parallelizable insert.</li> </ul> <p>Insertions, deletions, and updates are not supported in the Java™ Virtual-Table Interface.</p> | Flag     | Not set |
| <b>am_expr_pushdown</b> | A flag that enables the use of parameter descriptors.   | Flag     | Not set |
| <b>am_costfactor</b>    | A value by which the database server multiplies the cost that the <b>am_scancost</b> purpose function or method returns for a primary or secondary-access method. An <b>am_costfactor</b> value from 0.1 to 0.9 reduces the cost to a fraction of the value that <b>am_scancost</b> calculates. An <b>am_costfactor</b> value of 1.1 or greater increases the <b>am_scancost</b> value.   | Value    | 1.0     |
| <b>am_create</b>        | A keyword that you associate with a user-defined function or method (UDR) name that creates a virtual table or virtual index  | Task     | None    |
| <b>am_drop</b>          | A keyword that you associate with the name of a UDR that drops a virtual table or virtual index   | Task     | None    |
| <b>am_open</b>          | A keyword that you associate with the name of a UDR that makes a fragment, extspace, or sbspace available   | Task     | None    |

**Table 32. Purpose functions, purpose flags, and purpose values (continued)**

| Keyword             | Explanation  | Category | Default |
|---------------------|--|----------|---------|
| <b>am_close</b>     | A keyword that you associate with the name of a UDR that reverses the initialization that <b>am_open</b> performs  | Task     | None    |
| <b>am_insert</b>    | A keyword that you associate with the name of a UDR that inserts a row or an index entry   | Task     | None    |
| <b>am_delete</b>    | A keyword that you associate with the name of a UDR that deletes a row or an index entry   | Task     | None    |
| <b>am_update</b>    | A keyword that you associate with the name of a UDR that changes the values in a row or key  | Task     | None    |
| <b>am_stats</b>     | A keyword that you associate with the name of a UDR that builds statistics based on the distribution of values in storage spaces   | Task     | None    |
| <b>am_scancost</b>  | A keyword that you associate with the name of a UDR that calculates the cost of qualifying and retrieving data   | Task     | None    |
| <b>am_check</b>     | A keyword that you associate with the name of a UDR that tests the physical structure of a table or performs an integrity check on an index  | Task     | None    |
| <b>am_beginscan</b> | A keyword that you associate with the name of a UDR that sets up a scan  | Task     | None    |
| <b>am_endscan</b>   | A keyword that you associate with the name of a UDR that reverses the setup that <b>am_beginscan</b> initializes   | Task     | None    |
| <b>am_rescan</b>    | A keyword that you associate with the name of a UDR that scans for the next item from a previous scan to complete a join or subquery   | Task     | None    |
| <b>am_getnext</b>   | A keyword that you associate with the name of the required UDR that scans for the next item that satisfies a query   | Task     | None    |
| <b>am_getbyid</b>   | A keyword that you associate with the name of a UDR that fetches data from a specific physical address; <b>am_getbyid</b> is available only for primary-access methods                                   | Task     | None    |
| <b>am_truncate</b>  | A keyword that you associate with the name of a UDR that deletes all rows of a virtual table (primary-access method) or that deletes all corresponding keys in a virtual index (secondary-access method) | Task     | None    |

The following rules apply to the purpose-option specifications in the CREATE ACCESS\_METHOD and ALTER ACCESS\_METHOD statements:

- To specify multiple purpose options in one statement, separate them with commas.
- The CREATE ACCESS\_METHOD statement must specify a user-defined function or method name that corresponds to the **am\_getnext** keyword.

The ALTER ACCESS\_METHOD statement cannot drop the function or method name that corresponds to **am\_getnext** but can modify it.

- The ALTER ACCESS\_METHOD statement cannot add, drop, or modify the **am\_sptype** value.
- You can specify the **am\_defopclass** value only with the ALTER ACCESS\_METHOD statement.

You must first register a secondary-access method with the CREATE ACCESS\_METHOD statement before you can assign a default operator class.

## Purpose Options for XA Data Source Types

The CREATE XADATASOURCE TYPE statement specifies purpose functions that provide access to data from external data sources that comply with the X/Open XA standards. These functions also enable external data to be processed in accordance with the transactional semantics of Informix®. Only databases that use transaction logging, such as ANSI-compliant databases and Informix® databases that support explicit transactions, can support transaction coordination.

The following statement creates a new XA data source type called **MQSeries®**, owned by user **informix**.

```
CREATE XADATASOURCE TYPE 'informix'.MQSeries(
    xa_flags      = 1,
    xa_version    = 0,
    xa_open       = informix.mqseries_open,
    xa_close      = informix.mqseries_close,
    xa_start      = informix.mqseries_start,
    xa_end        = informix.mqseries_end,
    xa_rollback   = informix.mqseries_rollback,
    xa_prepare    = informix.mqseries_prepare,
    xa_commit     = informix.mqseries_commit,
    xa_recover    = informix.mqseries_recover,
    xa_forget     = informix.mqseries_forget,
    xa_complete   = informix.mqseries_complete);
```

These values represent the fields in the XA Switch Structure, as listed in the file **\$INFORMIXDIR/incl/public/xa.h**. The order of specifications in this example follows the order of column names in the **sysxasourcetypes** system catalog table, but they can be listed in any order, provided that no item is repeated. The **xa\_flags** and **xa\_version** values must be numbers; the rest must be names of UDRs that the Transaction Manager can invoke. These UDRs must already exist in the database before you can issue a CREATE XADATASOURCE TYPE statement that references them among its purpose option specifications.

The DROP FUNCTION or DROP ROUTINE statement cannot drop a UDR that is listed among the purpose options of a CREATE XADATASOURCE TYPE statement until all of the XA datasource types that were defined using the UDR are dropped.

For information about how to use the UDRs in the previous example to coordinate transactions with external XA data sources, see the *Informix® DataBlade® API Programmer's Guide*.

For information about the MQDataBlade module, see the *Informix® Database Extensions User's Guide*.

## Return Clause

The Return clause specifies the data type of a value or values that a user-defined function returns. You can use this segment in UDR definitions.

### Syntax

| Element          | Description  | Restrictions  | Syntax                                  |
|------------------|--|---|---|
| <i>parameter</i> | Name that you declare here for a returned parameter of the UDR | Must be unique among returned <i>parameter</i> names of the UDR. If any returned value of the UDR has a name, then all must have names. | <a href="#">Identifier on page 1456</a> |

### Usage

For compatibility with earlier Informix® releases, you can create SPL functions with the CREATE PROCEDURE statement. (That is, you can include a Return clause in CREATE PROCEDURE statements.) Use CREATE FUNCTION, however, to create new SPL routines that return one or more values.

After the Return clause has indicated what data types are to be returned, you can use the RETURN statement of SPL at any point in the statement block to return SPL variables that correspond to the values in the Return clause.

## Limits on Returned Values

An SPL function can specify more than one data type in the Return clause.

685. Stored Procedure Language only

686. See [Subset of SQL Data Types on page 1500](#)

An external function (a function written in the C or the Java™ language) can specify only one data type in the Return clause, but an external function can return more than one row of data if it is an iterator function. For more information, see [ITERATOR on page 1509](#).

## Subset of SQL Data Types

The built-in SQL data types that a user-defined function (UDF) can return are language-dependent.

For more information, see the table that follows. See also [Data Type on page 1163](#).

UDFs written in a given language can return values of any built-in data type except the types that are marked with an X in the following table.

| <b>Data Type</b> | <b>C</b> | <b>Java™</b> | <b>SPL</b> |
|------------------|----------|--------------|------------|
| BIGSERIAL        | X        | X            | X          |
| BLOB             | X        |              |            |
| CLOB             | X        |              |            |
| BYTE             | X        | X            |            |
| TEXT             | X        | X            |            |
| BSON             | ?        | X            | ?          |
| JSON             | ?        | X            | ?          |
| COLLECTION       |          | X            |            |
| LIST             |          | X            |            |
| MULTISET         |          | X            |            |
| ROW              |          | X            |            |
| SET              |          | X            |            |
| SERIAL           | X        | X            | X          |
| SERIAL8          | X        | X            | X          |

In Informix®, if you use a complex data type in the Return clause, the calling user-defined routine must define variables of the appropriate complex types to hold the values that the C or SPL user-defined function returns.

User-defined functions can return a value of opaque or distinct data types that are defined in the database.

The default precision of a DECIMAL value that an SPL function returns is 16 digits. For a function to return a DECIMAL with a different number of significant digits, you must specify the returned precision explicitly in the *data type* specification of the Return clause.

## Using the REFERENCES Clause to Point to a Simple Large Object

A user-defined function cannot return a BYTE or TEXT value (collectively called *simple large objects*) directly. A user-defined function can, however, use the REFERENCES keyword to return a descriptor that contains a pointer to a BYTE or TEXT object. The following example shows how to select a TEXT column within an SPL routine and then return the value:

```
CREATE FUNCTION sel_text()
  RETURNING REFERENCES text;
  DEFINE blob_var REFERENCES text;
  SELECT blob_col INTO blob_var
    FROM blob_table WHERE key_col = 10;
  RETURN blob_var;
END FUNCTION;
```

For simple large objects that are column values from the Projection list of a query, as in this example, the pointer in the returned descriptor references the **sysblobs.spacename** value from the system catalog, based on the BYTE or TEXT column definition.

For simple large objects that do not correspond to columns of permanent tables, however, the pointer references the dbspace of the database in which the UDR is defined. This is the default storage location for a BYTE or TEXT object that a UDR returns, when no location from the **sysblobs** table is known to the database server.

The DB-Access session in the following example creates two routines, `udr1` and `udr2`, that each return the descriptor of a TEXT object:

```
CREATE DATABASE db WITH LOG;

CREATE TABLE t (c2 TEXT);
CREATE TABLE t1 (c2 TEXT);
LOAD FROM "t.unl" INSERT INTO t;

CREATE FUNCTION udr1 ( param_1
  REFERENCES TEXT DEFAULT NULL )
  RETURNING REFERENCES TEXT
  WITH (NOT VARIANT)
  DEFINE var1 REFERENCES TEXT;
  ON EXCEPTION
    RETURN param_1;
  END EXCEPTION;
  SELECT t.c2 udr1_col1
    INTO var1 FROM t;
  RETURN var1;
END FUNCTION;

CREATE PROCEDURE udr2 ( OUT param_1
  REFERENCES TEXT DEFAULT NULL )
  RETURNING INT;
  SELECT t.c2 udr1_col1
    INTO param_1 FROM t;
  RETURN 1;
END PROCEDURE;

SELECT udr1(t.c2) query_1_col1 FROM t
  INTO TEMP mytemp;
```

```
SELECT c2, slv1 FROM t1
WHERE udr2(slv1#TEXT) > 0
INTO TEMP mytemp;
```

In the SELECT statements that call these UDRs, the TEXT object that each query returns to the mytemp temporary table are stored in the dbspace of the db database.

## Returning a value from another database

The value returned from another database by a user-defined function (UDF) is restricted to a smaller set of data types than the return value of a function that accesses only the local database. Similarly, functions that access databases of other server instances are more restricted in the data types of their return values than functions that return values from other databases of the local database server.

For UDFs that access tables or views outside the local database, only the following data types are valid as return values:

Figure 15. Return data types in distributed function calls

| Element                    | Description   | Restrictions  | Syntax  |
|----------------------------|---|---|---|
| <i>built-in_non-opaque</i> | Atomic built-in data type that is not opaque  | Type cannot be complex, serial, BYTE, or TEXT   | <a href="#">Data Type on page 1163</a>        |
| <i>built-in_opaque</i>     | Atomic built-in data type that is opaque. <b>Note 1</b> does not apply to BOOLEAN, BSON, JSON, or LVARCHAR. | See built-in opaque data types list in <a href="#">Data Types in Cross-Database Transactions on page 779</a>      | <a href="#">Data Type on page 1163</a>        |
| <i>distinct</i>            | DISTINCT type whose base type is another DISTINCT type  | Root of this hierarchy must be a BSON, BOOLEAN, JSON, LVARCHAR, or an atomic <i>built-in non-opaque</i> data type | <a href="#">DISTINCT Types in Distributed</a> |

687. Not valid in cross-server operations

| Element            | Description                             | Restrictions   | Syntax                                      |
|--------------------|---|--|---|
|                    |   |  | <a href="#">Operations on page 1184</a>     |
| <i>max</i>         | Maximum size in bytes. Default is 2048. | Must be an integer, where 1 <i>max</i> 32,739  | <a href="#">Literal Number on page 1419</a> |
| <i>opaque_UD T</i> | A user-defined opaque data type         | Must be cast explicitly to a built-in type by a cast defined in every participating database | <a href="#">Identifier on page 1456</a>     |

### Important:

The diagram above shows the generalized logical hierarchy of the base types for any DISTINCT data type. Using the `DISTINCT OF` keywords recursively, however, as in the diagram above, is not valid SQL syntax. The `CREATE DISTINCT TYPE` statement must specify exactly one base type for the new DISTINCT type. To create a hierarchy of DISTINCT data types, you must issue a separate `CREATE DISTINCT TYPE` statement for every DISTINCT type in the hierarchy. For the SQL syntax to define a new DISTINCT data type, see the topic [CREATE DISTINCT TYPE statement on page 210](#).

## Usage

Whether UDFs can return data from other databases depends on

- the transaction-logging status of the participating databases,
- and the data type of the returned value or values,

For a function invoked in one database to return a value from another database, both participating databases must be of compatible transaction-logging types:

- A function invoked in a database that was not created as `MODE ANSI` cannot retrieve data from an ANSI-compliant database.
- Conversely, a function called in an ANSI-compliant database cannot retrieve data from a database that was not created as `MODE ANSI`, whether or not the non-ANSI database supports transaction logging.
- A function call in a database without transaction logging can retrieve data only from unlogged databases.
- A function from a database with explicit transaction logging cannot retrieve data from an unlogged database. It can return data only from databases with explicit logging.

In the last case, a UDF called in a database that supports explicit transactions can return a value from another non-ANSI database that uses buffered or unbuffered logging, whether or not both databases use the same buffered or unbuffered logging mode.

If the databases are of incompatible logging types, however, the valid data types of return values is an empty set, rather than any of the types that the syntax diagram identifies.

Sections that follow describe what data types can be returned in distributed function calls.

## Return values from cross-database operations

If the Return clause specifies a value (or multiple values, in the case of an SPL function) from another database of the local Informix® instance, the following data types are supported as the return data type:

- Built-in data types that are not opaque or complex
- Most of the *built-in opaque data types*, as listed in [Data Types in Cross-Database Transactions on page 779](#)
- Any DISTINCT type based on a supported built-in type
- Any DISTINCT type based on one of those DISTINCT types
- Any user-defined type (UDT) that is cast explicitly to one of the supported built-in types.

The UDF and all of the DISTINCT types, opaque UDTs, data type hierarchies, and casts must have exactly the same definitions in each of the participating databases. The same data-type restrictions apply to a value that an external function returns from another database of the local Informix® instance.

For more information about data types that are supported in distributed operations across two or more databases of the same database server, see [Data Types in Cross-Database Transactions on page 779](#). For the data type hierarchies that are valid for DISTINCT data types in distributed transactions, see [DISTINCT Types in Distributed Operations on page 1184](#).

## Return values from cross-server operations

From databases of other Informix® instances, however, UDFs can specify only the following as a parameter or as a returned data type:

- Built-in data types that are not opaque
- BOOLEAN
- BSON
- JSON
- LVARCHAR
- DISTINCT of built-in types that are not opaque
- DISTINCT of BOOLEAN
- DISTINCT of BSON
- DISTINCT of JSON
- DISTINCT of LVARCHAR
- DISTINCT of the DISTINCT types in this list.

The definitions of the UDF and of any data type hierarchies, casts, and DISTINCT types must be exactly the same in each of the participating databases. Except for the BOOLEAN, DISTINCT, BSON, JSON, and LVARCHAR data types that are identified in the previous list, UDFs cannot return any other built-in opaque data type or opaque UDTs in cross-server function calls.

For more information about data types that are supported in distributed operations across two or more Informix® instances, see [Data Types in Cross-Server Transactions on page 781](#). For the data type hierarchies that are valid for DISTINCT data types in distributed transactions, see [DISTINCT Types in Distributed Operations on page 1184](#).

## Named Return Parameters

You can declare names for the returned parameters of an SPL routine, or a name for the single value that an external function can return.

If an SPL routine returns more than one value, you must either declare names for all of the returned parameters, or else none of them can have names. The names must be unique. Here is an example of named parameters:

```
CREATE PROCEDURE p (inval INT DEFAULT 0)
RETURNING INT AS serial_num,
          CHAR(10) AS name,
          INT AS points;
RETURN (inval + 1002), Newton, 100;
END PROCEDURE;
```

Executing this UDR would return:

| serial_num | name   | points |
|------------|--------|--------|
| 1002       | Newton | 100    |

There is no relationship between the names of returned parameters and the names of any variables in the body of the routine. For example, you can define a function to return an INTEGER as **xval**, but in the body of the same function, a variable declared as **xval** could be of the data type INTERVAL YEAR TO MONTH.

## Using the LIKE Clause

Use the LIKE clause to avoid recreating the SPL whenever the tables in the RETURNING clause changes.

If you want to change any of the columns in the SPL routine, you can use **LIKE** syntax with the **RETURN** clause. Here is an example of named parameters with **LIKE** syntax:

```
CREATE PROCEDURE p (inval INT DEFAULT 0)
RETURNING serial_num LIKE testtab.serial_num,
          name LIKE testtab.name,
          points LIKE testtab.points;
RETURN (inval + 1002), "Newton", 100;
END PROCEDURE;
```

## Cursor and Noncursor Functions

A *cursor* function can fetch returned values one by one by iterating the generated result set of returned values. Such a function is an *implicitly iterated function*.

A function that returns only one set of values (such as one or more columns from a single row of a table) is a *noncursor* function.

The Return clause is valid in a cursor function or in a noncursor function. In the following example, the Return clause can return zero (0) or one value in a noncursor function. In a cursor function, however, it returns more than one row from a table, and each returned row contains zero or one value:

```
RETURNING INT;
```

In the following example, the Return clause can return zero (0) or two values if it occurs in a noncursor function. In a cursor function, however, it returns more than one row from a table, and each returned row contains zero or two values:

```
RETURNING INT, INT;
```

In both of the preceding examples, the receiving function or program must be written appropriately to accept the information that the function returns.

## Routine modifier

A routine modifier specifies characteristics of how a user-defined routine (UDR) behaves.

### Syntax

Adding or Modifying a Routine Modifier <sup>691</sup>

Dropping a Routine Modifier

Dropping a Routine Modifier

688689

### NOT

### VARIANT

### NEGATOR

690

### CLASS ITERATOR PARALLELIZABLE

688

### HANDLENULLS INTERNAL

### COSTFUNC PERCALL\_COST

### SELFUNC SELCONST

### STACK

| Element          | Description  | Restrictions   | Syntax                                  |
|------------------|--|--|---|
| <i>parameter</i> | Name that you declare here for a returned parameter of the UDR | Must be unique among returned parameters of UDRs. If any returned value of the UDR has a name, then all must have names. | <a href="#">Identifier on page 1456</a> |

### Usage

If you drop an existing modifier in an ALTER FUNCTION, ALTER PROCEDURE, or ALTER ROUTINE statement, the database server sets the value of the modifier to the default value, if a default exists.

Some modifiers are available only with user-defined functions. For information about whether a specific routine modifier applies only to user-defined functions (that is, if it does not apply to user-defined procedures), see the description of the

688. C routines

689. SPL routines

690. External routines only

691. See [Adding or Modifying a Routine Modifier on page 1507](#)

modifier in the sections that follow. In these sections, as elsewhere in this document, *external* refers to UDRs written in the C or Java™ languages. Features valid for only one language are so designated in the previous diagrams.

Except for VARIANT and NOT VARIANT modifiers, none of the options in this segment are valid for SPL routines.

### Example

The following statement includes an external routine reference for a Java™ language UDR. You must first register *demo\_jar* using the procedure **install\_jar**(*<absolute path>**<jar file name>*,*<internal registered name>*).

```
CREATE FUNCTION delete_order(int) RETURNING int
  WITH (NOT VARIANT)
  EXTERNAL NAME 'informix.demo_jar:delete_order.delete_order()'
  LANGUAGE JAVA;
```

## Adding or Modifying a Routine Modifier

Use this segment in the ALTER FUNCTION, ALTER PROCEDURE, or ALTER ROUTINE statement to add or modify values for routine modifiers of a UDR.

**SELFUNC** = *sel\_func*

**SELCONST** = *selectivity*

**STACK** = *stack\_size*

692. C language

693. Stored Procedure Language

694. External routines only

| Element            | Description   | Restrictions   | Syntax                                      |
|--------------------|---|--|---|
| <i>class_name</i>  | Virtual processor (VP) class in which to run the external routine   | Any C UDR must run in the CPU VP or in a user-defined VP class       | <a href="#">Quoted String on page 1424.</a> |
| <i>cost</i>        | CPU use cost for each invocation of a C-language UDR. Default is 0. | Integer; 1 $\leq$ cost $\leq 2^{31}-1$ (highest cost).               | <a href="#">Literal Number on page 1419</a> |
| <i>cost_func</i>   | Name of a companion user-defined cost function to run               | Must have same owner as the UDR. Execute privilege is needed to run. | <a href="#">Identifier on page 1456</a>     |
| <i>neg_func</i>    | Negator function that can be invoked instead of the UDR             | Must have same owner as the UDR. Execute privilege is needed to run. | <a href="#">Identifier on page 1456</a>     |
| <i>sel_func</i>    | Name of a companion user-defined selectivity function to invoke     | Must have same owner as the UDR. Execute privilege is needed to run. | <a href="#">Identifier on page 1456</a>     |
| <i>selectivity</i> | CPU use cost for each invocation of a C-language UDR. Default is 0. | See <a href="#">Concept of Selectivity on page 1512.</a>             | <a href="#">Literal Number on page 1419</a> |
| <i>stack_size</i>  | Size (in bytes) of stack of the thread that runs the C-language UDR | Must be a positive integer   | <a href="#">Literal Number on page 1419</a> |

You can add these modifiers in any order. If you list the same modifier more than once, the last setting overrides any previous values.

## Modifier Descriptions

The following sections describe the modifiers that you can use to help the database server optimally execute a UDR.

### CLASS

Use the CLASS modifier to specify the name of a virtual-processor (VP) class in which to run an external routine. A user-defined VP class must be defined before the UDR can be invoked.

You can execute C UDRs in the following types of VP classes:

- The CPU virtual-processor class (CPU VP)
- A user-defined virtual-processor class.

If you omit the CLASS modifier to specify a VP class for a UDR written in C, the UDR runs in the CPU VP. User-defined VP classes protect the database server from ill-behaved C UDRs. An ill-behaved C UDR has at least one of the following characteristics:

- It runs in the CPU VP for a long time without yielding.
- It is not thread safe.
- It calls an unsafe operating-system routine.

A well-behaved C UDR has none of these characteristics. Execute only well-behaved C UDRs in the CPU VP.

**Warning:** Execution of an ill-behaved C UDR in the CPU VP can cause serious interference with the operation of the database server, and the UDR might not produce correct results. For a discussion of ill-behaved UDRs, see the *Informix® DataBlade® API Programmer's Guide*.

By default, a UDR written in Java™ runs in a Java™ virtual processor class (JVP). Therefore, the CLASS modifier is optional for a UDR written in Java™. However, use the CLASS modifier when you register a UDR written in Java™ to improve readability of your SQL statements.

## COSTFUNC (C)

Use the COSTFUNC modifier to specify the cost of a UDR. The *cost* of the UDR is an estimate of the time required to execute it.

Occasionally, the cost of a UDR depends on its inputs. In that case, you can use a user-defined function to calculate a cost that depends on input values.

To execute *cost\_func*, you must have Execute privilege on it and on the UDR.

## HANDLESNULLS

Use the HANDLESNULLS modifier to specify that a C UDR can handle NULL values that are passed to it as arguments. If you do not specify HANDLESNULLS for a C language UDR, and if you pass to it an argument that has a NULL value, the UDR does not execute and returns a NULL value.

By default, a C language UDR does *not* handle NULL values.

The HANDLESNULLS modifier is not available for SPL routines because SPL routines handle NULL values by default.

## INTERNAL

Use the INTERNAL modifier with an external routine to specify that an SQL or SPL statement cannot call the external routine. An external routine that is specified as INTERNAL is not considered during routine resolution. Use the INTERNAL modifier for external routines that define access methods, language managers, and so on.

By default, an external routine is *not* internal; that is, an SQL or SPL statement can call the routine.

## ITERATOR

Use the ITERATOR modifier with external functions to specify that the function is an *iterator function*. An iterator function is a function that returns a single element per function call to return a set of data; that is, it is called with an initial call and zero or more subsequent calls until the set is complete.

By default, an external C or Java™ language function is *not* an iterator function.

An SPL iterator function requires the RETURN WITH RESUME statement, rather than the ITERATOR modifier.

In ESQL/C, an iterator function requires a cursor. The cursor allows the client application to retrieve the values one at a time with the FETCH statement.

For more information on how to write iterator functions, see *Informix® User-Defined Routines and Data Types Developer's Guide* and the *Informix® DataBlade® API Programmer's Guide*.

For information about using an iterator function with a virtual table interface in the FROM clause of a query, see [Iterator Functions on page 801](#).

## NEGATOR

Use the NEGATOR modifier with UDRs that return Boolean values.

The NEGATOR modifier designates another user-defined function, called a *negator function*, as a companion to the current function. A negator function takes the same arguments as its companion function, in the same order, but returns the Boolean complement.

That is, if a function returns `TRUE` for a given set of arguments, its negator function returns `FALSE` when passed the same arguments, in the same order. For example, the following functions are negator functions:

```
equal(a,b)
notequal(a,b)
```

Both functions take the same arguments, in the same order, but return complementary Boolean values. When it is more efficient to do so, the query optimizer can use the negator function instead of the function that you specify.

To invoke a user-defined function that has a negator function, you must have the Execute privilege on both functions. In addition, the function must have the same owner as its negator function.

## PARALLELIZABLE

Use the PARALLELIZABLE modifier to indicate that an external routine can be executed in parallel in the context of a parallelizable data query (PDQ).

By default, an external routine is non-parallelizable; that is, it executes in sequence.

If your UDR has a complex or smart large object data type as either a parameter or a returned value, you cannot use the `PARALLELIZABLE` modifier.

If you specify the `PARALLELIZABLE` modifier for an external routine that cannot be parallelizable, the database server returns a runtime error.

A C language UDR that calls only PDQ thread-safe DataBlade® API functions is parallelizable. These categories of DataBlade® API functions are PDQ thread safe:

- Data handling
  - An exception in this category is that collection manipulation functions (`mi_collection_*`) are not PDQ thread safe.
- Session, thread, and transaction management
- Function execution
- Memory management
- Exception handling
- Callbacks
- Miscellaneous

For details of the DataBlade® API functions that are included in each category, see the *Informix® DataBlade® API Function Reference*.

If your C language UDR calls a function that is not included in one of these categories, it is not PDQ thread safe and is therefore not parallelizable.

To parallelize Java™ language UDR calls, the database server must have multiple instances of JVPs. UDRs written in the Java™ language and that open a JDBC connection are not parallelizable.

## PERCALL\_COST (C)

Use the `PERCALL_COST` modifier to specify the approximate CPU usage cost that a UDR incurs each time it executes.

The optimizer uses the cost you specify to determine the order in which to evaluate SQL predicates in the UDR for best performance. For example, the following query has two predicates joined by a logical AND:

```
SELECT * FROM tab1 WHERE func1() = 10 AND func2() = 'abc';
```

In this example, if one predicate returns `FALSE`, the optimizer need not evaluate the other predicate.

The optimizer uses the specified cost to order the predicates so that the least expensive predicate is evaluated first. The CPU usage cost must be an integer between 1 and  $2^{31}-1$ , with 1 the lowest cost and  $2^{31}-1$  the most expensive.

To calculate an approximate cost per call, add the following two figures:

- The number of lines of code executed each time the UDR is called
- The number of predicates that require an I/O access

The default cost per execution is 0. When you drop the PERCALL\_COST modifier, the cost per execution returns to 0.

## SELCONST (C)

Use the SELCONST modifier to specify the selectivity of a UDR. The selectivity of the UDR is an estimate of the fraction of the rows that the query will select.

The value of selectivity constant, **selconst**, is a floating-point number between 0 and 1 that represents the fraction of the rows for which you expect the UDR to return TRUE.

## SELFUNC (C)

Use the SELFUNC modifier with a C UDR to name a companion user-defined function, called a selectivity function, to the current UDR. The selectivity function provides selectivity information about the current UDR to the optimizer.

The selectivity of a UDR is an estimate of the fraction of the rows that the query will select. That is, it is an estimate of the number of times the UDR will execute.

To execute *sel\_func*, you must have Execute privilege on it and on the UDR.

## Concept of Selectivity

*Selectivity* is an attribute of queries that performs a search based on an equality condition. The selectivity of the query depends inversely on the proportion of qualifying rows. The smaller the proportion of qualifying rows among all the rows in FROM clause table objects, the more selective is the query.

For example, the following query has a search condition based on the **customer\_num** column in the **customer** table:

```
SELECT * FROM customer WHERE customer_num = 102;
```

Because each row in the table has a different customer number, this query is highly selective. In contrast, the following query has low selectivity:

```
SELECT * FROM customer WHERE state = 'CA';
```

Because most of the rows in the **customer** table are for customers in California, more than half of the rows in the table would be returned.

## Restrictions on the SELFUNC Modifier

The selectivity function that you specify with the SELFUNC modifier has specific requirements.

The selectivity function that you specify must satisfy the following criteria:

- It must take the same number of arguments as the current UDR.
- The data type of each argument must be SELFUNCARGS.

- It must return a value of type FLOAT between 0 and 1, which represents the percentage of selectivity of the function. (1 is highly selective; 0 is not at all selective.)
- It can be written in any language that the database server supports.

A user who invokes the UDR must have the Execute privilege both on that UDR and on the selectivity function that the SELFUNC modifier specifies.

Both the UDR and the selectivity function must have the same owner.

For information on how to use the **mi\_funcarg\*** functions to extract information about the arguments of a selectivity function, see the *Informix® DataBlade® API Programmer's Guide*.

## STACK (C)

Use the STACK modifier with a C UDR to override the default stack size that the STACKSIZE configuration parameter specifies.

The STACK modifier specifies the size (in bytes) of the thread stack, which a user thread that executes the UDR uses to hold information such as routine arguments and returned values from functions.

A UDR needs to have enough stack space for all its local variables. For a particular UDR, you might need to specify a stack size larger than the default size to prevent stack overflow.

When a UDR that includes the STACK modifier executes, the database server allocates a thread-stack size of the specified number of bytes. Once the UDR completes execution, subsequent UDRs execute in threads with a stack size that the STACKSIZE configuration parameter specifies (unless any of these subsequent UDRs have also specified the STACK modifier).

For more information about the thread stack, see your *Informix® Administrator's Guide* and the *Informix® DataBlade® API Function Reference*.

## VARIANT and NOT VARIANT

Use the VARIANT and NOT VARIANT modifiers with C user-defined functions and SPL functions. A function is *variant* if it returns different results when it is invoked with the same arguments or if it modifies a database or variable state. For example, a function that returns the current date or time is a variant function.

By default, user-defined functions are variant. If you specify NOT VARIANT when you create or modify a user-defined function, the function cannot contain any SQL statements.

If the user-defined function is nonvariant, the database server might cache the returned values of expensive functions. You can create functional indexes only on nonvariant functions. For more information on functional indexes, see [CREATE INDEX statement on page 253](#).

In ESQL/C, you can specify VARIANT or NOT VARIANT in this clause or in the EXTERNAL Routine Reference. For more information, see [External Routine Reference on page 1454](#). If you specify the modifier in both places, however, you must use the same modifier in both clauses.

## Routine Parameter List

Use the appropriate part of the Routine Parameter List segment whenever you see a reference to a Routine Parameter List in a syntax diagram.

### Syntax

Routine Parameter List

,

**IN OUT**

**INOUT**

Parameter

Parameter

*parameter*

<sup>695</sup>

Subset of SQL Data Type <sup>696</sup>

**LIKE** *table.column*

**DEFAULT** *value*

**REFERENCES**

**BYTE TEXT**

**DEFAULT NULL**

| Element          | Description   | Restrictions   | Syntax  |
|------------------|---|--|---|
| <i>column</i>    | Name of a column whose data type is declared for <i>parameter</i> | Must exist in the specified table  | <a href="#">Database Object Name on page 1450</a> |
| <i>parameter</i> | Name of a parameter of the UDR                                    | Name is required for SPL routines  | <a href="#">Identifier on page 1456</a>           |
| <i>table</i>     | Table that contains <i>column</i>                                 | The table must exist in the database   | <a href="#">Identifier on page 1456</a>           |
| <i>value</i>     | Default used if UDR is called with no value for <i>parameter</i>  | Must be a literal, of the same data type as <i>parameter</i> . For opaque types, an input function must be defined | <a href="#">Literal Number on page 1419</a>       |

695. External routines only

696. See [Subset of SQL Data Types on page 1515](#)

## Usage

A *parameter* is a formal argument in the declaration of a UDR. (When you subsequently invoke a UDR that has parameters, you must substitute a specific argument value for the parameter, unless the parameter has a default value.)

The name of the parameter is optional for external routines of HCL Informix®.

When you create a UDR, you declare a *name* and *data type* for each parameter. You can specify the data type directly, or use the LIKE or REFERENCES clause to specify the data type. You can optionally specify a default value.

You can define any number of SPL routine parameters, but the total length of all parameters passed to an SPL routine must be less than 2 gigabytes.

No more than nine arguments to a UDR written in the Java™ language can be DECIMAL data types of SQL that the UDR declares as BigDecimal data types of the Java™ language.

Any C language UDR that returns an opaque data type must specify **opaque\_type** in the `var binary` declaration of the C host variable.

### Related reference

[Arguments on page 1433](#)

## Subset of SQL Data Types

Serial and large-object data types are not valid as parameters. A UDR can declare a parameter of any other data type defined in the database, including any built-in data types except BIGSERIAL, BLOB, BYTE, CLOB, SERIAL, SERIAL8, or TEXT.

On Informix®, a parameter can also be a complex data type or a UDT, but complex data types are not valid for parameters of external UDRs written in the Java™ language.

For information about the data types of Informix® that are valid as parameters or return values of routines that access tables or views outside the local database, see [Returning a value from another database on page 1502](#).

## Using the LIKE Clause

Use the LIKE clause to specify that the data type of a parameter is the same as a column defined in the database. If the ALTER TABLE statement changes the data type of the column, the data type of the parameter also changes.

In Informix®, if you use the LIKE clause to declare any parameter, you cannot overload the UDR. For example, suppose you create the following user-defined procedure:

```
CREATE PROCEDURE cost (a LIKE tableX.colY, b INT)
. . .
END PROCEDURE;
```

You cannot create another procedure named **cost()** in the same Informix® database with two arguments. You can, however, create a procedure named **cost()** with a number of arguments other than two. (Another way to circumvent this restriction on the LIKE clause is through user-defined data types.)

## Using the REFERENCES Clause

Use the REFERENCES clause to specify that a parameter contains BYTE or TEXT data. The REFERENCES keyword allows you to use a pointer to a BYTE or TEXT object as a parameter. If you use the DEFAULT NULL option in the REFERENCES clause, and you call the UDR without a parameter, a NULL value is used as the default value.

## Using the DEFAULT Clause

Use the DEFAULT keyword followed by an expression to specify a default value for a parameter. If you provide a default value for a parameter, and the UDR is called with fewer arguments than were defined for that UDR, the default value is used. If you do not provide a default value for a parameter, and the UDR is called with fewer arguments than were defined for that UDR, the calling application receives an error.

The following example shows a CREATE FUNCTION statement that specifies a default value for a parameter. This function finds the square of the *i* parameter. If the function is called without specifying the argument for the *i* parameter, the database server uses the default value 0 for the *i* parameter.

```
CREATE FUNCTION square_w_default
  (i INT DEFAULT 0) {Specifies default value of i}
  RETURNING INT; {Specifies return of INT value}
  DEFINE j INT; {Defines routine variable j}
  LET j = i * i; {Finds square of i and assigns it to j}
  RETURN j; {Returns value of j to calling module}
END FUNCTION;
```

**Warning:** When you specify a date value as the default value for a parameter, make sure to specify 4 digits instead of 2 digits for the year. When you specify a 2-digit year, the **DBCENTURY** environment variable setting can affect how the database server interprets the date value, so the UDR might not use the default value that you intended. For more information, see the *Informix® Guide to SQL: Reference*.

## Specifying OUT Parameters for User-Defined Routines

When you register a user-defined routine of Informix®, you can use the OUT keyword to specify that any parameter in the list is an OUT parameter. Each OUT parameter corresponds to a value the routine returns indirectly, through a pointer. The value that the routine returns through the pointer is an extra value, in addition to any values that it returns explicitly.

After you have registered a user-defined function that has one or more OUT parameters, you can use the function with a statement-local variable (SLV) in a SELECT statement. (For information about statement-local variables, see [Statement-Local Variable Expressions on page 1365](#).)

If you specify any OUT parameters, and you use Informix®-style parameters, the arguments are passed to the OUT parameters by reference. The OUT parameters are not significant in determining the routine signature.

For example, the following declaration of a C user-defined function allows you to return an extra value through the **y** parameter:

```
int my_func( int x, int *y );
```

Register the C function with a CREATE FUNCTION statement similar to this:

```
CREATE FUNCTION my_func( x INT, OUT y INT )
  RETURNING INT
  EXTERNAL NAME "/usr/lib/local_site.so"
  LANGUAGE C
END FUNCTION;
```

In the next example, this Java™ method returns an extra value by passing an array:

```
public static String allVarchar(String arg1, String[] arg2)
  throws SQLException
{
  arg2[0] = arg1;
  return arg1;
}
```

To register this as a UDF, use a statement similar to the following example:

```
CREATE FUNCTION all_varchar(VARCHAR(10), OUT VARCHAR(7))
  RETURNING VARCHAR(7)
  WITH (class = "jvp")
  EXTERNAL NAME 'informix.testclasses.jlm.Param.allVarchar(java.lang.String,
  java.lang.String[ ])'
  LANGUAGE JAVA;
```

## Specifying INOUT Parameters for a User-Defined Routine

UDRs that are written in the SPL, C, or Java™ languages can also support INOUT parameters. When the UDR is invoked, a value for each INOUT parameter is passed by reference as an argument to the UDR.

When the UDR completes execution, it can return a modified value for the INOUT parameter to the calling context. The INOUT parameter can be of any data type that Informix® supports, including user-defined and complex data types, with the following exceptions:

- Serial types (BIGSERIAL, SERIAL, and SERIAL8)
- Simple large object types (BYTE and TEXT).

In the following example, the CREATE PROCEDURE statement registers a C routine that has a single INOUT parameter:

```
CREATE PROCEDURE CALC ( INOUT param1 float )
  EXTERNAL NAME "$INFORMIXDIR/etc/myudr.so(calc)"
  LANGUAGE C;
```

An SPL routine can invoke other UDRs that have OUT or INOUT parameters, if those UDRs are written in the SPL or C language. An SPL routine cannot, however, invoke a Java™ UDR whose arguments include OUT or INOUT parameters.

Support for invoking UDRs that have named or unnamed ROW arguments from an SPL routine has the following dependencies on the parameter type of the ROW argument, and on the programming language of the invoked UDR:

- SPL routines can invoke C UDRs that have ROW arguments that are IN parameters, but cannot invoke C UDRs that have ROW arguments that are OUT or INOUT parameters.
- SPL routines can invoke SPL UDRs that have ROW arguments of any parameter type, including IN, OUT, and INOUT.

You can assign INOUT parameters to statement-local variables (SLVs), which the section [Statement-Local Variable Expressions on page 1365](#) describes.

## Shared-Object Filename

Use a shared-object filename to specify a pathname to an executable object file when you register or alter an external routine.

### Syntax

Shared-Object File

<sup>697</sup>

C Shared-Object File<sup>699</sup>

<sup>698</sup>

Java™ Shared-Object File<sup>700</sup>

### Usage

If the IFX\_EXTEND\_ROLE configuration parameter is set to `1` or to `ON`, only users to whom the DBSA has granted the built-in EXTEND role are authorized to use this segment. (Whether or not IFX\_EXTEND\_ROLE is enabled, you must hold the Resource privilege or the DBA privilege on the database, and you must also hold the Usage privilege on the external programming language in which the UDR is written, before you can create, drop, or alter an external UDR.)

The Database Server Administrator should include in the DB\_LIBRARY\_PATH configuration parameter settings every file system where the security policy authorizes DataBlade® modules and UDRs to reside. Unless DB\_LIBRARY\_PATH is absent or has no setting, the database server cannot access a file that this segment specifies unless its pathname begins with a string that exactly matches one of the values of DB\_LIBRARY\_PATH.

For example, if "**\$INFORMIXDIR/extend**" is one of the DB\_LIBRARY\_PATH values on a Linux™ system, then shared-object files can have pathnames within the **\$INFORMIXDIR/extend** file system or its subdirectories. This directory is also the file system where built-in DataBlade® modules reside.

The syntax by which you specify a shared-object filename depends on whether the external routine is written in the C language or in the Java™ language. Sections that follow describe each of these external languages.

For more information about the context in which a shared-object filename appears within EXTERNAL NAME clause of the ALTER FUNCTION, ALTER PROCEDURE, ALTER ROUTINE, CREATE FUNCTION, and CREATE PROCEDURE statements, see the related reference, External Routine Reference.

## C Shared-Object File

To specify the location of a C shared-object file, you can specify the path to the dynamically-loaded executable file within a quoted pathname or as a variable.

The C shared-object filename is specified by the following syntax:

C Shared-Object File

*quote*

*\$environment\_var*

*/ .*

*pathname*

*(symbol)*

*quote*

*\$variable*

| Element                | Description   | Restrictions  | Syntax                                       |
|------------------------|---|---|--|
| <i>environment_var</i> | Platform-independent indicator                            | Must begin with a dollar sign ( \$ )                  | <a href="#">Identifier on page 1456</a>      |
| <i>pathname</i>        | Pathname to the file                                      | See notes that follow this table                      | Must conform to operating system conventions |
| <i>quote</i>           | Either single ( ' ) or double ( " ) quotation mark symbol | Opening and closing quotation mark symbols must match | Literal symbol (either ' or " )              |
| <i>symbol</i>          | Entry point to the file                                   | Must be enclosed in parentheses                       | Must conform to operating system conventions |
| <i>variable</i>        | Platform-independent indicator                            | Must begin with a dollar sign ( \$ )                  | Must conform to C language conventions       |

The following rules affect *pathname* and filename specifications in C:

- A filename (with no *pathname*) can specify an internal function.
- You can omit the period ( . ) symbol if *pathname* is relative to the current directory when the CREATE or ALTER statement is run.
- On UNIX™, an absolute pathname must begin with a slash ( / ) symbol, and each directory name must end with a slash ( / ) symbol.
- On Windows™, an absolute pathname must begin with a backslash ( \ ) symbol, and each directory name must end with a backslash ( \ ) symbol.

- The filename at the end of *pathname* must have the **.so** file extension and must refer to an executable file in a shared object library.
- Use a *symbol* only if the entry point to the dynamically loadable executable object file has a different name from the UDR that you are registering with CREATE FUNCTION or CREATE PROCEDURE.
- If you specify a *variable*, it must contain the full pathname to the executable file.
- You can include white-space characters, such as blank spaces or tab characters, within a quoted pathname.

## Java™ Shared-Object File

To specify the name of a Java™ shared-object file, specify the name of the static Java™ method to which the UDR corresponds and the location of the Java™ binary that defines the method.

Java™ Shared-Object File

*quote*

Jar Name<sup>701</sup>

:

*package\_id*.

*class\_id* . *method\_id*

(

, *java\_type*

)**RETURNS***java\_type*

*quote*

| Element           | Description  | Restrictions  | Syntax  |
|-------------------|--|---|---|
| <i>class_id</i>   | Java™ class whose method implements the UDR                  | Class must exist in the <b>.jar</b> file that Jar Name identifies   | Must conform to rules for Java™ identifiers       |
| <i>java_type</i>  | Java™ data type for a parameter in the Java-method signature | Must be defined in a JDBC class or by an SQL-to-Java mapping        | Must conform to rules for Java™ identifiers       |
| <i>method_id</i>  | Name of the Java™ method that implements the UDR             | Must exist in the Java™ class that <i>java_class_name</i> specifies | Must conform to rules for Java™ identifiers       |
| <i>package_id</i> | Name of package that contains the Java™ class                | Must exist  | Must conform to rules for Java™ identifiers       |
| <i>quote</i>      | Single ( ' ) or double ( " ) quotation mark delimiters       | Opening and closing quotation marks must match                      | Literal symbol ( ' or " ) entered at the keyboard |

Before you can create a UDR written in the Java™ language, you must assign a jar identifier to the external jar file with the **sqlj.install\_jar** procedure. (For more information, see [sqlj.install\\_jar](#).) You can include the Java™ signature of the method that implements the UDR in the shared-object filename.

701. See [Jar Name on page 1471](#)

- If you do *not* specify the Java™ signature, the routine manager determines the *implicit* Java™ signature from the SQL signature in the CREATE FUNCTION or CREATE PROCEDURE statement.

It maps SQL data types to the corresponding Java™ data types with the JDBC and SQL-to-Java mappings. For information on mapping user-defined data types to Java™ data types, see `sqlj.setUDTextName`.

- If you do specify the Java™ signature, the routine manager uses this *explicit* Java™ signature as the name of the Java™ method to use.

For example, if the Java™ method `explosiveReaction()` implements the Java™ UDR `sql_explosive_reaction()` as discussed in `sqlj.install_jar`, its shared-object filename could be:

```
course_jar:Chemistry.explosiveReaction
```

The preceding shared-object filename provides an implicit Java™ signature. The following shared-object filename is the equivalent with an explicit Java™ signature:

```
course_jar:Chemistry.explosiveReaction(int)
```

## Specific Name

Use a specific name to declare an identifier for a UDR that is unique in the database or name space. Use the Specific Name segment whenever you see a reference to a specific name in a syntax diagram.

### Syntax

Specific Name

*owner*.

*specific\_id*

| Element            | Description            | Restrictions  | Syntax                                  |
|--------------------|------------------------|---|---|
| <i>owner</i>       | Owner of the UDR       | No more than 32 bytes. Must be same as <i>owner</i> of function or procedure name of this UDR. See also <a href="#">Restrictions on the Owner Name on page 1522</a> . | <a href="#">Owner name on page 1488</a> |
| <i>specific_id</i> | Unique name of the UDR | Must be no more than 128 bytes long. See also <a href="#">Restrictions on the Specific Name on page 1522</a> .  | <a href="#">Identifier on page 1456</a> |

### Usage

A *specific name* is a unique identifier that the CREATE PROCEDURE or CREATE FUNCTION statement declares as an alternative name for a UDR.

Because you can overload routines, a database can have more than one UDR with the same name and different parameter lists. You can assign a UDR a specific name that uniquely identifies the specific UDR.

If you declare a specific name when you create the UDR, you can later use that name when you alter, drop, grant, or revoke privileges, or update statistics on that UDR. Otherwise, you need to include the parameter data types with the UDR name, if the name alone does not uniquely identify the UDR.

## Restrictions on the Owner Name

When you declare a specific name, the *owner* must be the same *authorization identifier* that qualifies the function name or procedure name of the UDR that you create. That is, whether or not you specify the owner name to qualify either the UDR name or the specific name or both, the names of the *owner* must match.

When you specify no owner name in the DDL statement that creates a UDR, Informix® uses the login name of the user who creates the UDR. Therefore, if you specify the owner name in one location and not the other, the owner name that you specify must match your user ID.

## Restrictions on the Specific Name

In a database that is not ANSI-compliant, *specific\_id* must be unique among routine names within the database. Two UDRs cannot have the same *specific\_id*, even if they have different owners.

In an ANSI-compliant database, the combination *owner.specific\_id* must be unique. That is, the specific name must be unique among UDRs that have the same owner.

## Statement Block

Use a statement block to specify SPL and SQL operations to take place when an SPL statement that includes this segment is executed.

### Syntax

Statement Block

DEFINE Statement<sup>702</sup>

ON EXCEPTION Statement<sup>703</sup>

EXECUTE FUNCTION Statement<sup>704</sup>

EXECUTE PROCEDURE Statement<sup>705</sup>

Subset of SPL Statements<sup>706</sup>

Subset of SQL Statements<sup>707</sup>

;

**BEGIN**Statement Block**END**

702. See [DEFINE](#) on page 1089

703. See [ON EXCEPTION](#) on page 1124 and [Identifier](#) on page 1456

704. See [EXECUTE FUNCTION](#) statement on page 549

705. See [EXECUTE PROCEDURE](#) statement on page 557

706. See [Subset of SPL Statements Valid in the Statement Block](#) on page 1523

707. See [SQL Statements Valid in SPL Statement Blocks](#) on page 1523

## Usage

SPL and SQL statements can appear in a *statement block*, a set of zero or more statements that can define the scope of a variable or of the ON EXCEPTION statement. If a statement block is empty, no operation takes place when control of execution within the SPL routine passes to the empty SPL statement block.

## Subset of SPL Statements Valid in the Statement Block

The diagram for the [Statement Block on page 1522](#) refers to this section. You can use any of the following SPL statements in the statement block:

- <<*Label*>>
- CALL
- CASE
- CONTINUE
- EXIT
- FOR
- FOREACH
- GOTO
- IF
- LET
- LOOP
- RAISE EXCEPTION
- RETURN
- SYSTEM
- TRACE
- WHILE

GOTO and << *Label* >>, however, are not valid in ON EXCEPTION statement blocks.

## SQL Statements Valid in SPL Statement Blocks

The diagram for the [Statement Block on page 1522](#) refers to this section. Most SQL statements are valid in SPL statement blocks, except for the statements that are listed below. The following SQL statements are *not* valid in an SPL statement block:

- CLOSE DATABASE
- CONNECT
- CREATE DATABASE
- CREATE FUNCTION
- CREATE FUNCTION FROM
- CREATE PROCEDURE

- CREATE PROCEDURE FROM
- CREATE ROUTINE FROM
- DATABASE
- DISCONNECT
- DROP DATABASE
- EXECUTE
- FLUSH
- INFO
- LOAD
- OUTPUT
- PUT
- RENAME DATABASE
- SET AUTOFREE
- SET CONNECTION
- UNLOAD
- UPDATE STATISTICS

For example, you cannot close the current database or connect to a new database within an SPL routine. Similarly, you cannot drop the current SPL routine within the same routine. You can, however, drop another SPL routine.

Only two forms of the SELECT statement are valid in queries within SPL routines:

- You can use the INTO TEMP clause to put the result of the SELECT statement into a temporary table.
- You can use the SELECT ... INTO form of the SELECT statement to put the resulting values into SPL variables.

When you include the ORDER BY clause in the SELECT ... INTO TEMP or the SELECT ... INTO *variable* statement, you imply that the query returns more than one row. The database server issues an error if you specify the ORDER BY clause without a FOREACH loop to process the returned rows individually within the SPL routine.

If an SPL routine is called as part of a data-manipulation language (DML) statement, additional restrictions exist. For more information, see [Restrictions on SPL Routines in Data-Manipulation Statements on page 1525](#).

## Nested Statement Blocks

You can use the BEGIN and END keywords to delimit a statement block that is nested within another statement block.

## Scope of Reference of SPL Variables and Exception Handlers

The BEGIN and END keywords can limit the scope of SPL variables and exception handlers. Declarations of variables and definitions of exception handlers inside a BEGIN and END statement block are local to that statement block and are not visible from outside the statement block. The following code uses a BEGIN and END statement block to delimit the scope of reference of variables:

```

CREATE DATABASE demo;
CREATE TABLE tracker (
  who_submitted CHAR(80), -- Show what code was running.
  value INT,             -- Show value of the variable.
  sequential_order SERIAL -- Show order of statement execution.
);
CREATE PROCEDURE demo_local_var()
DEFINE var1, var2 INT;
  LET var1 = 1;
  LET var2 = 2;
  INSERT INTO tracker (who_submitted, value)
    VALUES ('var1 param before sub-block', var1);
BEGIN
  DEFINE var1 INT; -- same name as global parameter.
  LET var1 = var2;
  INSERT INTO tracker (who_submitted, value)
    VALUES ('var1 var defined inside the "IF/BEGIN".', var1);
END
INSERT INTO tracker (who_submitted, value)
  VALUES ('var1 param after sub-block (unchanged!)', var1);
END PROCEDURE;
EXECUTE PROCEDURE demo_local_var();
SELECT sequential_order, who_submitted, value FROM tracker
ORDER BY sequential_order;

```

This example declares three variables, two of which are named **var1**. (Name conflicts are created here to illustrate which variables are visible. Using the same name for different variables is generally not recommended, because conflicting names of variables can make your code more difficult to read and to maintain.)

Because of the statement block, only one **var1** variable is in scope at a time.

The **var1** variable that is declared inside the statement block is the only **var1** variable that can be referenced from within the statement block.

The **var1** variable that is declared outside the statement block is not visible within the statement block. Because it is out of scope, it is unaffected by the change in value to the **var1** variable that takes place inside the statement block. After all the statements run, the outer **var1** still has a value of **1**.

The **var2** variable is visible within the statement block because it was not superseded by a name conflict with a block-specific variable.

## Restrictions on SPL Routines in Data-Manipulation Statements

If you call the SPL routine in a SQL statement that is not a data-manipulation language (DML) statement (namely EXECUTE FUNCTION or EXECUTE PROCEDURE), the SPL routine can execute any statement that is not listed in the section [SQL Statements Valid in SPL Statement Blocks on page 1523](#).

If you call the SPL routine as part of a DML statement (namely, an INSERT, UPDATE, DELETE, MERGE, or SELECT statement), the routine cannot execute any of the following SQL statements:

- ALTER ACCESS\_METHOD
- ALTER FRAGMENT

- ALTER INDEX
- ALTER SEQUENCE
- ALTER TABLE
- BEGIN WORK
- COMMIT WORK
- CREATE ACCESS\_METHOD
- CREATE AGGREGATE
- CREATE DISTINCT TYPE
- CREATE OPAQUE TYPE
- CREATE OPCLASS
- CREATE ROLE
- CREATE ROW TYPE
- CREATE SEQUENCE
- CREATE TRIGGER
- DELETE
- DROP ACCESS\_METHOD
- DROP AGGREGATE
- DROP INDEX
- DROP OPCLASS
- DROP ROLE
- DROP ROW TYPE
- DROP SEQUENCE
- DROP SYNONYM
- DROP TABLE
- DROP TRIGGER
- DROP TYPE
- DROP VIEW
- INSERT
- MERGE
- RENAME COLUMN
- RENAME DATABASE
- RENAME SEQUENCE
- RENAME TABLE
- ROLLBACK WORK
- SET CONSTRAINTS
- TRUNCATE
- UPDATE

HCL Informix® issues error -675 if an SPL routine whose calling context is a DML statement attempts to execute any of the SQL statements listed above.

These restrictions do not apply to an SPL routine that is invoked by a trigger, because in this case the SPL routine is not called by the DML statement, and therefore can include any SQL statement, such as UPDATE, INSERT and DELETE, that is not listed among the [SQL Statements Valid in SPL Statement Blocks on page 1523](#).

## Transactions in SPL Routines

In a database that is not ANSI-compliant, you can use the BEGIN WORK and COMMIT WORK statements in an SPL statement block to start a transaction, to finish a transaction, or start and finish a transaction in the same SPL routine. If you start a transaction in a routine that is executed remotely, you must finish the transaction before the routine exits.

As previously noted, however, the ROLLBACK WORK statement is not valid in an SPL statement block.

## Support for roles and user identity

You can use roles with SPL routines. You can execute role-related SQL statements (CREATE ROLE, DROP ROLE, GRANT, REVOKE, and SET ROLE) and a user who holds the SETSESSIONAUTH privilege can issue SET SESSION AUTHORIZATION statements in an SPL routine. Within an SPL routine, you can also use the GRANT statement

- to grant discretionary access privileges to roles,
- or grant label-based access credentials (LBAC) to roles,
- or grant other roles to roles.

An SPL routine can also use the REVOKE statement to cancel the access privileges, the LBAC credentials, or the roles that a role holds.

Access privileges, roles, and LBAC credentials that a user has acquired in an SPL routine by enabling a role or by a SET SESSION AUTHORIZATION statement are not automatically relinquished after the SPL routine that granted the privilege, role, or LBAC credential completes execution. What was granted persists until a subsequent REVOKE operation cancels the effect of the GRANT operation.

For further information about roles, see the [CREATE ROLE statement on page 303](#), [DROP ROLE statement on page 521](#), [GRANT statement on page 592](#), [REVOKE statement on page 727](#), and [SET ROLE statement on page 994](#) in Chapter 2.

## Appendixes

### Keywords of SQL for HCL Informix®

This appendix lists the keywords in the HCL Informix® implementation of SQL for Informix®.

The ISO standard SQL language has many keywords. Some are designated as *reserved words* and others as *non-reserved words*. In ISO SQL, reserved words cannot be used as identifiers for database objects, such as tables, columns, and so on. To use a reserved word as a name in a valid SQL statement requires a delimited identifier ([Delimited Identifiers on page 1458](#)) that you enclose between double ( " ") quotation marks.

In contrast, the dialect of SQL that HCL Informix® database servers implement has few reserved words in the sense of a character string that obeys the rules for identifiers ([Identifier on page 1456](#)) but always produces a compilation error or

runtime error when used as an identifier. Your application might encounter restricted functionality, however, or unexpected results, if you define an SPL routine that has the same name as a built-in SQL function, expression, or operator.

Do not declare any of the keywords in this appendix as SQL identifiers. If you do, errors or syntactic ambiguities can occur if the identifier appears in a context where the keyword is valid. In addition, your code will be more difficult to read and to maintain. Informix® reserves the prefixes `ifx_` and `sys` for built-in routines and database objects. Do not use keywords of C or C++ (or of any other programming language that you will be using in an embedded mode) in your database structures. The notations `IFX_*` and `SYS*` (where `*` is a wildcard character for "any string") in the alphabetized lists that follow. These indicate that those prefixes should be avoided in user-defined identifiers of database objects. (Keywords of SQL that begin with those suffixes are not listed in this appendix, whose goal is to assist HCL Informix® users in avoiding names that are used internally by the database server.)

If you receive an error message that seems unrelated to the SQL statement that caused the error, review this appendix to see whether a keyword is used as an identifier.

To avoid using a keyword as an identifier, you can qualify the identifier with an owner name or modify the identifier. For example, rather than name a database object `CURRENT`, you might name it `o_current` or `juanita.current`. For a discussion of potential problems in using keywords as identifiers, and of additional workarounds for specific keywords, see [Use of Keywords as Identifiers on page 1458](#). See also *Informix® Guide to SQL: Tutorial* for more information about using keywords as identifiers in SQL applications.

## Guide to SQL: Reference

The *Informix® Guide to SQL: Reference* contains the reference information for the system catalog tables, data types, and environment variables of the HCL Informix® dialect of the SQL language, as implemented in HCL Informix®. These topics also include information about the `stores_demo`, `sales_demo`, and `superstore_demo` databases that are included with HCL Informix®.

This information is intended for the following users:

- Database users
- Database administrators
- Database security administrators
- Database application programmers.

This information assumes that you have the following background:

- A working knowledge of your computer, your operating system, and the utilities that your operating system provides.
- Some experience working with relational databases or exposure to database concepts.
- Some experience with computer programming.

## System catalog tables

The *system catalog* consists of tables and views that describe the structure of the database. Sometimes called the *data dictionary*, these table objects contain everything that the database knows about itself. Each system catalog table contains information about specific elements in the database. Each database has its own system catalog.

These topics provide information about the structure, content, and use of the system catalog tables. It also contains information about the Information Schema, which provides information about the tables, views, and columns in all the databases of the HCL Informix® instance to which your user session is currently connected.

## Objects That the System Catalog Tables Track

The system catalog tables maintain information about the database, including the following categories of database objects:

- Tables, views, synonyms, and table fragments
- Columns, constraints, indexes, and index fragments
- Distribution statistics for tables, indexes, and fragments
- Triggers on tables, and INSTEAD OF triggers on views
- Procedures, functions, routines, and associated messages
- Authorized users, roles, and privileges to access database objects
- LBAC security policies, components, labels, and exemptions
- Data types and casts
- User-defined aggregate functions
- Access methods and operator classes
- Sequence objects
- Storage spaces for BLOB and CLOB objects
- External optimizer directives
- Inheritance relationships
- XA data sources and XA data source types
- Trusted user and surrogate user information

## Using the system catalog

HCL Informix® automatically generate the system catalog tables when you create a database. You can query the system catalog tables as you would query any other table in the database. The system catalog tables for a newly created database are located in a common area of the disk called a *dbspace*. Every database has its own system catalog tables. All tables and views in the system catalog have the prefix **sys** (for example, the **systables** system catalog table).

Not all tables with the prefix **sys** are true system catalog tables. For example, the **syscdr** database supports the Enterprise Replication feature. Non-catalog tables, however, have a **tabid**  $\geq 100$ . System catalog tables all have a **tabid**  $< 100$ . See later in this section and [SYSTABLES on page 1609](#) for more information about **tabid** numbers that the database server assigns to tables, views, synonyms, and (in HCL Informix®) sequence objects.

**i** **Tip:** Do not confuse the system catalog tables of a database with the tables in the **sysmaster**, **sysutils**, **syscdr**, or (for HCL Informix®) the **sysadmin** and **sysuser** databases. The names of tables in those databases also have the **sys** prefix, but they contain information about an entire database server, which might manage multiple databases. Information in the **sysadmin**, **sysmaster**, **sysutils**, **syscdr**, and **sysuser** tables is primarily useful for database server administrators (DBSAs). See also the *Informix® Administrator's Guide* and .

The database server accesses the system catalog constantly. Each time an SQL statement is processed, the database server accesses the system catalog to determine system privileges, add or verify table or column names, and so on.

For example, the following CREATE SCHEMA block adds the **customer** table, with its indexes and privileges, to the **stores\_demo** database. This block also adds a view, **california**, which restricts the data of the **customer** table to only the first and last names of the customer, the company name, and the telephone number for all customers who reside in California.

```
CREATE SCHEMA AUTHORIZATION maryl
CREATE TABLE customer (customer_num SERIAL(101), fname CHAR(15),
    lname CHAR(15), company CHAR(20), address1 CHAR(20), address2 CHAR(20),
    city CHAR(15), state CHAR(2), zipcode CHAR(5), phone CHAR(18))
GRANT ALTER, ALL ON customer TO cathl WITH GRANT OPTION AS maryl
GRANT SELECT ON customer TO public
GRANT UPDATE (fname, lname, phone) ON customer TO nhowe
CREATE VIEW california AS
    SELECT fname, lname, company, phone FROM customer WHERE state = 'CA'
CREATE UNIQUE INDEX c_num_ix ON customer (customer_num)
CREATE INDEX state_ix ON customer (state)
```

To process this CREATE SCHEMA block, the database server first accesses the system catalog to verify the following information:

- The new table and view names do not already exist in the database. (If the database is ANSI-compliant, the database server verifies that the new names do not already exist for the specified owners.)
- The user has permission to create tables and grant user privileges.
- The column names in the CREATE VIEW and CREATE INDEX statements exist in the **customer** table.

In addition to verifying this information and creating two new tables, the database server adds new rows to the following system catalog tables:

- **systables**
- **syscolumns**
- **sysviews**
- **systabauth**
- **syscolauth**

- **sysindexes**
- **sysindices**

### Rows added to the **systables** system catalog table

The following two new rows of information are added to the **systables** system catalog table after the CREATE SCHEMA block is run.

| Column name      | First row  | Second row |
|------------------|------------|------------|
| <b>tablename</b> | customer   | california |
| <b>owner</b>     | maryl      | maryl      |
| <b>partnum</b>   | 16778361   | 0          |
| <b>tabid</b>     | 101        | 102        |
| <b>rowsize</b>   | 134        | 134        |
| <b>ncols</b>     | 10         | 4          |
| <b>nindexes</b>  | 2          | 0          |
| <b>nrows</b>     | 0          | 0          |
| <b>created</b>   | 01/26/2007 | 01/26/2007 |
| <b>version</b>   | 1          | 0          |
| <b>tabtype</b>   | T          | V          |
| <b>locklevel</b> | P          | B          |
| <b>npused</b>    | 0          | 0          |
| <b>fextsize</b>  | 16         | 0          |
| <b>nextsize</b>  | 16         | 0          |
| <b>flags</b>     | 0          | 0          |
| <b>site</b>      |            |            |
| <b>dbname</b>    |            |            |

Each table recorded in the **systables** system catalog table is assigned a **tabid**, a system-assigned sequential number that uniquely identifies each table in the database. The system catalog tables receive 2-digit **tabid** numbers, and the user-created tables receive sequential **tabid** numbers that begin with 100.

### Rows added to the **syscolumns** system catalog table

The CREATE SCHEMA block adds 14 rows to the **syscolumns** system catalog table. These rows correspond to the columns in the table **customer** and the view **california**, as the following example shows.

| colname      | tabid | colno | coltype | collength | colmin | colmax |
|--------------|-------|-------|---------|-----------|--------|--------|
| customer_num | 101   | 1     | 262     | 4         |        |        |
| fname        | 101   | 2     | 0       | 15        |        |        |
| lname        | 101   | 3     | 0       | 15        |        |        |
| company      | 101   | 4     | 0       | 20        |        |        |
| address1     | 101   | 5     | 0       | 20        |        |        |
| address2     | 101   | 6     | 0       | 20        |        |        |
| city         | 101   | 7     | 0       | 15        |        |        |
| state        | 101   | 8     | 0       | 2         |        |        |
| zipcode      | 101   | 9     | 0       | 5         |        |        |
| phone        | 101   | 10    | 0       | 18        |        |        |
| fname        | 102   | 1     | 0       | 15        |        |        |
| lname        | 102   | 2     | 0       | 15        |        |        |
| company      | 102   | 3     | 0       | 20        |        |        |
| phone        | 102   | 4     | 0       | 18        |        |        |

In the **syscolumns** table, each column within a table is assigned a sequential column number, **colno**, that uniquely identifies the column within its table. In the **colno** column, the **fname** column of the **customer** table is assigned the value 2 and the **fname** column of the view **california** is assigned the value 1.

The **colmin** and **colmax** columns are empty. These columns contain values when a column is the first key (or the only key) in an index, has no NULL or duplicate values, and the UPDATE STATISTICS statement has been run.

### Rows added to the sysviews system catalog table

The database server also adds rows to the **sysviews** system catalog table, whose **viewtext** column contains each line of the CREATE VIEW statement that defines the view. In that column, the **x0** that precedes the column names in the statement (for example, **x0.fname**) operates as an alias that distinguishes among the same columns that are used in a self-join.

### Rows added to the systabauth system catalog table

The CREATE SCHEMA block also adds rows to the **systabauth** system catalog table. These rows correspond to the user privileges granted on **customer** and **california** tables, as the following example shows.

| grantor | grantee | tabid | tabauth  |
|---------|---------|-------|----------|
| maryl   | public  | 101   | su-idx-- |
| maryl   | cathl   | 101   | SU-IDXAR |
| maryl   | nhowe   | 101   | _*-----  |

| grantor | grantee | tabid | tabauth  |
|---------|---------|-------|----------|
|         | maryl   | 102   | SU-ID--- |

The **tabauth** column specifies the table-level privileges granted to users on the **customer** and **california** tables. This column uses an 8-byte pattern, such as **s** (Select), **u** (Update), **\*** (column-level privilege), **i** (Insert), **d** (Delete), **x** (Index), **a** (Alter), and **r** (References), to identify the type of privilege. In this example, the user **nhowe** has column-level privileges on the **customer** table. A hyphen (-) means the user has not been granted the privilege whose position the hyphen occupies within the **tabauth** value.

If the **tabauth** privilege code is in uppercase (for example, **s** for Select), the user has this privilege and can also grant it to others; but if the privilege code is lowercase (for example, **s** for Select), the user cannot grant it to others.

### Rows added to the syscolauth system catalog table

In addition, three rows are added to the **syscolauth** system catalog table. These rows correspond to the user privileges that are granted on specific columns in the **customer**, table as the following example shows.

| grantor | grantee | tabid | colno | colauth |
|---------|---------|-------|-------|---------|
| maryl   | nhowe   | 101   | 2     | -u-     |
| maryl   | nhowe   | 101   | 3     | -u-     |
| maryl   | nhowe   | 101   | 10    | -u-     |

The **colauth** column specifies the column-level privileges that are granted on the **customer** table. This column uses a 3-byte, pattern such as **s** (Select), **u** (Update), and **r** (References), to identify the type of privilege. For example, the user **nhowe** has Update privileges on the second column (because the **colno** value is 2) of the **customer** table (indicated by **tabid** value of 101).

### Rows added to the sysindexes or the sysindices table

The CREATE SCHEMA block adds two rows to the **sysindexes** system catalog table (the **sysindices** table for HCL Informix®). These rows correspond to the indexes created on the **customer** table, as the following example shows.

| idxname   | c_num_ix | state_ix |
|-----------|----------|----------|
| owner     | maryl    | maryl    |
| tabid     | 101      | 101      |
| idxtype   | U        | D        |
| clustered |          |          |
| part1     | 1        | 8        |
| part2     | 0        | 0        |
| part3     | 0        | 0        |

| idxname  | c_num_ix | state_ix |
|----------|----------|----------|
| part4    | 0        | 0        |
| part5    | 0        | 0        |
| part6    | 0        | 0        |
| part7    | 0        | 0        |
| part8    | 0        | 0        |
| part9    | 0        | 0        |
| part10   | 0        | 0        |
| part11   | 0        | 0        |
| part12   | 0        | 0        |
| part13   | 0        | 0        |
| part14   | 0        | 0        |
| part15   | 0        | 0        |
| part16   | 0        | 0        |
| levels   |          |          |
| leaves   |          |          |
| nunique  |          |          |
| clust    |          |          |
| idxflags |          |          |

In this table, the **idxtype** column identifies whether the created index requires unique values (U) or accepts duplicate values (D). For example, the **c\_num\_ix** index on the **customer.customer\_num** column is unique.

## Accessing the system catalog

Normal user access to the system catalog is read-only. Users with Connect or Resource privileges cannot alter the catalog, but they can access data in the system catalog tables on a read-only basis using standard SELECT statements.

For example, the following SELECT statement displays all the table names and corresponding **tabid** codes of user-created tables in the database:

```
SELECT tabname, tabid FROM systables WHERE tabid > 99
```

When you use DB-Access, only the tables that you created are displayed. To display the system catalog tables, enter the following statement:

```
SELECT tabname, tabid FROM systables WHERE tabid < 100
```

You can use the **SUBSTR** or the **SUBSTRING** function to select only part of a source string. To display the list of tables in columns, enter the following statement:

```
SELECT SUBSTR(tabname, 1, 18), tabid FROM systables
```

Although user **informix** can modify most system catalog tables, you should not update, delete, or insert any rows in them. Modifying the content of system catalog tables can affect the integrity of the database. However, you can safely use the **ALTER TABLE** statement to modify the size of the next extent of system catalog tables. Changing the next extent size does not affect extents that already exist.

For certain catalog tables of HCL Informix®, however, it is valid to add entries to the system catalog tables. For instance, in the case of the **syserrors** system catalog table and the **sysracemsgs** system catalog table, a DataBlade® module developer can directly insert entries that are in these system catalog tables.

---

## Update system catalog data

If you use the **UPDATE STATISTICS** statement to update the system catalog before executing a query or other data manipulation language (DML) statement, you can ensure that the information available to the query execution optimizer is current.

In HCL Informix®, the optimizer determines the most efficient strategy for executing SQL queries and other DML operations. The optimizer allows you to query the database without requiring you to consider fully which tables to search first in a join or which indexes to use. The optimizer uses information from the system catalog to determine the best query strategy.

When you delete or modify a table, the database server does not automatically update the related statistical data in the system catalog. For example, if you delete one or more rows in a table with the **DELETE** statement, the **nrows** column in the **systables** system catalog table, which holds the number of rows for that table, is not updated automatically.

The **UPDATE STATISTICS** statement causes the database server to recalculate data in the **systables**, **sysdistrib**, **syscolumns**, and **sysindices** system catalog tables, and in the **sysindexes** view. (For operations on fragmented tables where the **STATLEVEL** attribute is set to **FRAGMENT**, it also updates the **sysfragdist** and **sysfragments** system catalog tables.) After you run **UPDATE STATISTICS**, the **systables** system catalog table holds the correct value in the **nrows** column. If you specify **MEDIUM** or **HIGH** mode when you run **UPDATE STATISTICS**, the **sysdistrib** and (for fragment-level statistics) the **sysfragdist** system catalog tables hold the updated column-distribution data.

Whenever you modify a data table extensively, use the **UPDATE STATISTICS** statement to update data in the system catalog. For more information about the **UPDATE STATISTICS** statement, see the *Informix® Guide to SQL: Syntax*.

In case-sensitive databases that use the default database locale (U. S. English, ISO **8859-1** code set), character columns in these tables are CHAR and VARCHAR data types. For all other locales, character columns are the NLS data types, NCHAR and NVARCHAR. For information about differences in the collation order of character data types, see the *Informix® GLS User's Guide*. See also the [Data types on page 1625](#) chapter of this publication.

**Character columns in databases that are not case-sensitive**

In databases that are created with the NLSCASE INSENSITIVE keywords and that use the default database locale (U. S. English, ISO **8859-1** code set), character columns in system catalog tables are CHAR and VARCHAR data types, which support case-sensitive queries. For all other database locales, character column data types in the system catalog tables are the NLS data types, NCHAR and NVARCHAR, but with the following specific exceptions:

| <i>Table_name.Column_name</i> | <b>Data type</b> |
|-------------------------------|------------------|
| <b>sysams.am_sptype</b>       | CHAR(3)          |
| <b>syscolauth.colauth</b>     | CHAR(3)          |
| <b>sysdefaults.class</b>      | CHAR(1)          |
| <b>sysfragauth.fragauth</b>   | CHAR(6)          |
| <b>sysinherits.class</b>      | CHAR(1)          |
| <b>syslangauth.langauth</b>   | CHAR(1)          |
| <b>sysprocauth.procauth</b>   | CHAR(1)          |

| <i>Table_name.Column_name</i> | <b>Data type</b> |
|-------------------------------|------------------|
| <b>sysprocedures.mode</b>     | CHAR(1)          |
| <b>systabauth.tabauth</b>     | CHAR(9)          |
| <b>systriggers.event</b>      | CHAR(1)          |
| <b>sysxdttypeauth.auth</b>    | CHAR(2)          |

In each of these columns, case-sensitive encoding can record information that utilities of the database server require in queries on those system catalog tables. In a database that is case-insensitive, queries might return incorrect results from data stored in NCHAR or NVARCHAR columns, if different attributes of database objects are encoded as different cases of the same letter. To avoid the loss of information, CHAR data types are used for the system catalog columns listed above.

## SYSAGGREGATES

The **sysaggregates** system catalog table records user-defined aggregates (UDAs). The **sysaggregates** table has the following columns.

**Table 33. SYSAGGREGATES table column descriptions**

| <b>Column</b>       | <b>Type</b>   | <b>Explanation</b>  |
|---------------------|---------------|---|
| <b>name</b>         | VARCHAR(128 ) | Name of the aggregate   |
| <b>owner</b>        | CHAR(32)      | Name of the owner of the aggregate  |
| <b>aggid</b>        | SERIAL        | Unique code identifying the aggregate   |
| <b>init_func</b>    | VARCHAR(128 ) | Name of initialization UDR  |
| <b>iter_func</b>    | VARCHAR(128 ) | Name of iterator UDR  |
| <b>combine_func</b> | VARCHAR(128 ) | Name of combine UDR   |
| <b>final_func</b>   | VARCHAR(128 ) | Name of finalization UDR  |
| <b>handlesnulls</b> | BOOLEAN       | NULL-handling indicator: <ul style="list-style-type: none"> <li>• t = handles NULLs</li> <li>• f = does not handle NULLs</li> </ul> |

Each user-defined aggregate has one entry in **sysaggregates** that is uniquely identified by its identifying code (the **aggid** value). Only user-defined aggregates (aggregates that are not built in) have entries in **sysaggregates**.

Both a simple index on the **aggid** column and a composite index on the **name** and **owner** columns require unique values.

## SYSAMS

The **sysams** system catalog table contains information that is required for using built-in access methods and those created by the CREATE ACCESS\_METHOD statement of SQL.

The **sysams** table has the following columns.

**Table 34. SYSAMS table column descriptions**

| Column               | Type            | Explanation   |
|----------------------|-----------------|---|
| <b>am_name</b>       | VARCHAR(128, 0) | Name of the access method   |
| <b>am_owner</b>      | CHAR(32)        | Name of the owner of the access method  |
| <b>am_id</b>         | INTEGER         | Unique identifying code for an access method<br><br>This corresponds to the <b>am_id</b> columns in the <b>sysables</b> , <b>sysindices</b> , and <b>sysopclasses</b> tables.   |
| <b>am_type</b>       | CHAR(1)         | Type of access method: P = Primary; S = Secondary   |
| <b>am_sptype</b>     | CHAR(3)         | Types of spaces where the access method can exist: <ul style="list-style-type: none"> <li>• <b>A</b> means the access method supports extspaces and sbspaces. If the access method is built in, such as a B-tree, it also supports dbspaces.</li> <li>• <b>D</b> or <b>d</b> means the access method supports dbspaces only.</li> <li>• <b>DS</b> means the access method supports dbspaces and sbspaces.</li> <li>• <b>S</b> or <b>s</b> means the access method supports sbspaces only.</li> <li>• <b>X</b> or <b>x</b> means the access method supports extspaces only.</li> <li>• <b>SX</b> means the access method supports sbspaces and extspaces.</li> </ul> |
| <b>am_defopclass</b> | INTEGER         | Unique identifying code for default-operator class<br><br>Value is the <b>opclassid</b> from the entry for this operator class in the <b>sysopclasses</b> table.  |
| <b>am_keyscan</b>    | INTEGER         | Whether a secondary access method supports a key scan   |

Table 34. SYSAMS table column descriptions (continued)

| Column               | Type       | Explanation   |
|----------------------|------------|---|
|                      |            | (An access method supports a key scan if it can return a key and a rowid from a call to the <b>am_getnext</b> function.) (0 = FALSE; Non-zero = TRUE)                               |
| <b>am_unique</b>     | INTEGER    | Whether a secondary access method can support unique keys (0 = FALSE; Non-zero = TRUE)  |
| <b>am_cluster</b>    | INTEGER    | Whether a primary access method supports clustering (0 = FALSE; Non-zero = TRUE)  |
| <b>am_rowids</b>     | INTEGER    | Whether a primary access method supports rowids (0 = FALSE; Non-zero = TRUE)  |
| <b>am_readwrite</b>  | INTEGER    | Whether a primary access method can both read and write ( 0 = access method is read-only; Non-zero = access method is read/write )  |
| <b>am_parallel</b>   | INTEGER    | Whether an access method supports parallel execution (0 = FALSE; Non-zero = TRUE)   |
| <b>am_costfactor</b> | SMALLFLOAT | The value to be multiplied by the cost of a scan to normalize it to costing done for built-in access methods<br><br>The scan cost is the output of the <b>am_scancost</b> function. |
| <b>am_create</b>     | INTEGER    | The routine specified for the AM_CREATE purpose for this access method<br><br>Value = <b>procid</b> for the routine in the <b>sysprocedures</b> table.                              |
| <b>am_drop</b>       | INTEGER    | The routine specified for the AM_DROP purpose function for this access method   |
| <b>am_open</b>       | INTEGER    | The routine specified for the AM_OPEN purpose function for this access method   |
| <b>am_close</b>      | INTEGER    | The routine specified for the AM_CLOSE purpose function for this access method  |
| <b>am_insert</b>     | INTEGER    | The routine specified for the AM_INSERT purpose function for this access method   |
| <b>am_delete</b>     | INTEGER    | The routine specified for the AM_DELETE purpose function for this access method   |
| <b>am_update</b>     | INTEGER    | The routine specified for the AM_UPDATE purpose function for this access method   |

**Table 34. SYSAMS table column descriptions (continued)**

| Column                  | Type    | Explanation  |
|-------------------------|---------|--|
| <b>am_stats</b>         | INTEGER | The routine specified for the AM_STATS purpose function for this access method     |
| <b>am_scancost</b>      | INTEGER | The routine specified for the AM_SCANCOST purpose function for this access method  |
| <b>am_check</b>         | INTEGER | The routine specified for the AM_CHECK purpose function for this access method     |
| <b>am_beginscan</b>     | INTEGER | The routine specified for the AM_BEGINSCAN purpose function for this access method |
| <b>am_endscan</b>       | INTEGER | The routine specified for the AM_ENDSCAN purpose function for this access method   |
| <b>am_rescan</b>        | INTEGER | The routine specified for the AM_RESCAN purpose function for this access method    |
| <b>am_getnext</b>       | INTEGER | The routine specified for the AM_GETNEXT purpose function for this access method   |
| <b>am_getbyid</b>       | INTEGER | The routine specified for the AM_GETBYID purpose function for this access method   |
| <b>am_build</b>         | INTEGER | The routine specified for the AM_BUILD purpose function for this access method     |
| <b>am_init</b>          | INTEGER | The routine specified for the AM_INIT purpose function for this access method      |
| <b>am_truncate</b>      | INTEGER | The routine specified for the AM_TRUNCATE purpose function for this access method  |
| <b>am_expr_pushdown</b> | INTEGER | Whether parameter descriptors are supported (0 = FALSE; Non-zero = TRUE)           |

For each of the columns that contain a routine for a purpose function, the value is the **sysprocedures.procid** value for the corresponding routine.

A composite index on the **am\_name** and **am\_owner** columns in this table allows only unique values. The **am\_id** column has a unique index.

For information about access method functions, see the documentation of your access method.

## SYSATTRTYPES

The **sysattrtypes** system catalog table contains information about members of a complex data type. Each row of **sysattrtypes** contains information about elements of a collection data type or fields of a row data type.

The **sysattrtypes** table has the following columns.

**Table 35. SYSATTRTYPES table column descriptions**

| Column             | Type         | Explanation   |
|--------------------|--------------|---|
| <b>extended_id</b> | INTEGER      | Identifying code of an extended data type<br>Value is the same as in the <b>sysxdtypes</b> table ( <a href="#">SYSXDTYPES on page 1619</a> ). |
| <b>seqno</b>       | SMALLINT     | Identifying code of an entry having <b>extended_id</b> type   |
| <b>levelno</b>     | SMALLINT     | Position of member in collection hierarchy  |
| <b>parent_no</b>   | SMALLINT     | Value in the <b>seqno</b> column of the complex data type that contains this member   |
| <b>fieldname</b>   | VARCHAR(128) | Name of the field in a row type<br>Null for other complex data types  |
| <b>fieldno</b>     | SMALLINT     | Field number sequentially assigned by system (from left to right within each row type)  |
| <b>type</b>        | SMALLINT     | Code for the data type<br>See the description of <b>syscolumns.coltype</b> (page <a href="#">SYSCOLUMNS on page 1568</a> ).                   |
| <b>length</b>      | SMALLINT     | Length (in bytes) of the member   |
| <b>xtd_type_id</b> | INTEGER      | Code identifying this data type<br>See the description of <b>sysxdtypes.extended_id</b> ( <a href="#">SYSXDTYPES on page 1619</a> ).          |

Two indexes on the **extended\_id** column and the **xtd\_type\_id** column allow duplicate values. A composite index on the **extended\_id** and **seqno** columns allows only unique values.

## SYSAUTOLOCATE

The **sysautolocate** system catalog table indicates which dbspaces are available for automatic table fragmentation.

**Table 36. SYSAUTOLOCATE table column descriptions**

| Column          | Type                | Explanation   |
|-----------------|---------------------|---|
| <b>dbnum</b>    | INTEGER             | The ID number of the dbspace. 0 indicates multiple dbspaces.  |
| <b>dbname</b>   | VARCHAR(128,0)<br>) | The name of the dbspace. An asterisk (*) indicates multiple dbspaces.   |
| <b>pagesize</b> | SMALLINT            | The page size of the dbspace. 0 indicates multiple page sizes.  |
| <b>flags</b>    | INTEGER             | <ul style="list-style-type: none"> <li>• 1 = On. The dbspace is available for automatic table fragmentation.</li> <li>• 2 = Off. The dbspace is not available for automatic table fragmentation.</li> </ul> |

You add or remove dbspace from the list of available dbspace by running the `task()` or `admin()` SQL administration API function with one of the autolocate database arguments.

The **sysautolocate** system catalog table does not necessarily list every dbspace. For example, if all dbspaces are available for automatic table fragmentation, the table contains one row:

| dbnum | dbname | pagesize | flags |
|-------|--------|----------|-------|
| 0     | *      | 0        | 1     |

If all but one dbspace is available, the table contains two rows, for example:

| dbnum | dbname | pagesize | flags |
|-------|--------|----------|-------|
| 0     | *      | 0        | 1     |
| 12    | db12   | 8        | 2     |

If all but two dbspaces are unavailable, the table contains three rows, for example:

| dbnum | dbname | pagesize | flags |
|-------|--------|----------|-------|
| 0     | *      | 0        | 2     |
| 12    | db12   | 8        | 1     |
| 13    | db13   | 4        | 1     |

## SYSBLOBS

The **sysblobs** system catalog table specifies the storage location of BYTE and TEXT column values. Its name is based on a legacy term for BYTE and TEXT columns, blobs (also known as *simple large objects*), and does not refer to the BLOB data type of HCL Informix®. The **sysblobs** table contains one row for each BYTE or TEXT column, and has the following columns.

**Table 37. SYSBLOBS table column descriptions**

| Column           | Type         | Explanation  |
|------------------|--------------|--|
| <b>spacename</b> | VARCHAR(128) | Name of partition, dbspace, or family                    |
| <b>type</b>      | CHAR(1)      | Code identifying the type of storage media: M = Magnetic |

**Table 37. SYSBLOBS table column descriptions (continued)**

| Column       | Type     | Explanation                    |
|--------------|----------|--------------------------------|
| <b>tabid</b> | INTEGER  | Code identifying the table     |
| <b>colno</b> | SMALLINT | Column number within its table |

A composite index on **tabid** and **colno** allows only unique values.

For information about the location and size of chunks of blobspaces, dbspaces, and sbspaces for TEXT, BYTE, BLOB, and CLOB columns, see the *Informix® Administrator's Guide* and the .

## SYSCASTS

The **syscasts** system catalog table describes the casts in the database. It contains one row for each built-in cast, each implicit cast, and each explicit cast that a user defines. The **syscasts** table has the following columns.

**Table 38. SYSCASTS table column descriptions**

| Column               | Type         | Explanation  |
|----------------------|--------------|--|
| <b>owner</b>         | CHAR(32)     | Owner of cast (user <b>informix</b> for built-in casts and <i>user</i> name for implicit and explicit casts) |
| <b>argument_type</b> | SMALLINT     | Source data type on which the cast operates  |
| <b>argument_xid</b>  | INTEGER      | Code for the source data type specified in the <b>argument_type</b> column                                   |
| <b>result_type</b>   | SMALLINT     | Code for the data type returned by the cast  |
| <b>result_xid</b>    | INTEGER      | Data type code of the data type named in the <b>result_type</b> column                                       |
| <b>routine_name</b>  | VARCHAR(128) | Function or procedure implementing the cast  |
| <b>routine_owner</b> | CHAR(32)     | Name of owner of the function or procedure specified in the <b>routine_name</b> column                       |
| <b>class</b>         | CHAR(1)      | Type of cast: E = Explicit cast I = Implicit cast S = Built-in cast  |

If **routine\_name** and **routine\_owner** have NULL values, this indicates that the cast is defined without a routine. This can occur if both of the data types specified in the **argument\_type** and **result\_type** columns have the same length and alignment, and are passed by reference, or passed by value.

A composite index on columns **argument\_type**, **argument\_xid**, **result\_type**, and **result\_xid** allows only unique values. A composite index on columns **result\_type** and **result\_xid** allows duplicate values.

## SYSCHECKS

The **syschecks** system catalog table describes each check constraint defined in the database. Because the **syschecks** table stores both the ASCII text and a binary encoded form of the check constraint, it contains multiple rows for each check constraint. The **syschecks** table has the following columns.

**Table 39. SYSCHECKS table column descriptions**

| Column           | Type     | Explanation  |
|------------------|----------|--|
| <b>constrid</b>  | INTEGER  | Unique code identifying the constraint   |
| <b>type</b>      | CHAR(1)  | Form in which the check constraint is stored: B = Binary encoded s = Select T = Text |
| <b>seqno</b>     | SMALLINT | Line number of the check constraint  |
| <b>checktext</b> | CHAR(32) | Text of the check constraint   |

The text in the **checktext** column associated with **B** type in the type column is in computer-readable format. To view the text associated with a particular check constraint, use the following query with the appropriate **constrid** code:

```
SELECT * FROM syschecks WHERE constrid=10 AND type='T'
```

Each check constraint described in the **syschecks** table also has its own row in the **sysconstraints** table.

A composite index on the **constrid**, **type**, and **seqno** columns allows only unique values.

## SYSCHECKUDRDEP

The **syscheckudrdep** system catalog table describes each check constraint that is referenced by a user-defined routine (UDR) in the database. The **syscheckudrdep** table has the following columns.

**Table 40. SYSCHECKUDRDEP table column descriptions**

| Column               | Type    | Explanation                                  |
|----------------------|---------|--|
| <b>udr_id</b>        | INTEGER | Unique code identifying the UDR              |
| <b>constraint_id</b> | INTEGER | Unique code identifying the check constraint |

Each check constraint described in the **syscheckudrdep** table also has its own row in the **sysconstraints** system catalog table, where the **constrid** column has the same value as the **constraint\_id** column of **syscheckudrdep**.

A composite index on the **udr\_id** and **constraint\_id** columns requires that combinations of these values be unique.

## SYSCOLATTRIBS

The **syscolattribs** system catalog table describes the characteristics of smart large objects, namely CLOB and BLOB data types.

It contains one row for each sbspace referenced in the PUT clause of the CREATE TABLE statement or of the ALTER TABLE statement.

**Table 41. SYSCOLATTRIBS table column descriptions**

| Column            | Type         | Explanation  |
|-------------------|--------------|--|
| <b>tabid</b>      | INTEGER      | Code uniquely identifying the table  |
| <b>colno</b>      | SMALLINT     | Number of the column that contains the smart large object  |
| <b>extentsize</b> | INTEGER      | Pages in smart-large-object extent, expressed in KB  |
| <b>flags</b>      | INTEGER      | Integer representation of the combination (by addition) of hexadecimal values of the following parameters: <ul style="list-style-type: none"> <li>• LO_NOLOG (0x00000001 = 1) = The smart large object is not logged.</li> <li>• LO_LOG (0x00000010 = 2) = Logging of smart large objects conforms to current log mode of the database.</li> <li>• LO_KEEP_LASTACCESS_TIME (0x00000100 = 4) = Keeps a record of when this column was most recently accessed by a user.</li> <li>• LO_NOKEEP_LASTACCESS_TIME (0x00001000 = 8) = No record is kept of when this column was most recently accessed by a user.</li> <li>• HI_INTEG (0x00010000= 16) = Sbspace data pages have headers and footers to detect incomplete writes and data corruption.</li> <li>• MODERATE_INTEG (0x00100000= 32) = Data pages have headers but no footers.</li> </ul> |
| <b>flags1</b>     | INTEGER      | Reserved for future use  |
| <b>sbspace</b>    | VARCHAR(128) | Name of the sbspace  |

A composite index on the **tabid**, **colno**, and **sbspace** columns allows only unique combinations of these values.

## SYSCOLAUTH

The **syscolauth** system catalog table describes each set of discretionary access privileges granted on a column. It contains one row for each set of column-level privileges that are currently granted to a user, to a role, or to the PUBLIC group on a column in the database. The **syscolauth** table has the following columns.

| Column         | Type        | Explanation  |
|----------------|-------------|--|
| <b>grantor</b> | VARCHAR(32) | Authorization identifier of the grantor  |
| <b>grantee</b> | VARCHAR(32) | Authorization identifier of the grantee  |
| <b>tabid</b>   | INTEGER     | Code uniquely identifying the table  |
| <b>colno</b>   | SMALLINT    | Column number within the table   |
| <b>colauth</b> | CHAR(3)     | 3-byte pattern specifying column privileges: s or S = Select, u or U = Update, r or R = References |

If the **colauth** privilege code is uppercase (for example, **S** for Select), a user who has this privilege can also grant it to others. If the **colauth** privilege code is lowercase (for example, **s** for Select), the user who has this privilege cannot grant it to others. A hyphen ( - ) indicates the absence of the privilege corresponding to that position within the **colauth** pattern.

A composite index on the **tabid**, **grantor**, **grantee**, and **colno** columns allows only unique values. A composite index on the **tabid** and **grantee** columns allows duplicate values.

## SYSCOLDEPEND

The **syscoldepend** system catalog table tracks the table columns specified in check constraints and in NOT NULL constraints. Because a check constraint can involve more than one column in a table, the **syscoldepend** table can contain multiple rows for each check constraint; one row is created for each column involved in the constraint. The **syscoldepend** table has the following columns.

| Column          | Type     | Explanation                              |
|-----------------|----------|--|
| <b>constrid</b> | INTEGER  | Code uniquely identifying the constraint |
| <b>tabid</b>    | INTEGER  | Code uniquely identifying the table      |
| <b>colno</b>    | SMALLINT | Column number within the table           |

A composite index on the **constrid**, **tabid**, and **colno** columns allows only unique values. A composite index on the **tabid** and **colno** columns allows duplicate values.

See also the **syscheckudrdep** system catalog table in [SYSCHECKUDRDEP on page 1566](#), which lists every check constraint that is referenced by a user-defined routine.

See also the **sysreferences** table in [SYSREFERENCES on page 1599](#), which describes dependencies of referential constraints.

## SYSCOLUMNS

The **syscolumns** system catalog table describes each column in the database.

One row exists for each column that is defined in a table or view.

**Table 42. The SYSCOLUMNS table**

| Column         | Type         | Explanation   |
|----------------|--------------|---|
| <b>colname</b> | VARCHAR(128) | Column name   |
| <b>tabid</b>   | INTEGER      | Identifying code of table containing the column   |
| <b>colno</b>   | SMALLINT     | Column number<br><br>The system sequentially assigns this (from left to right within each table).   |
| <b>coltype</b> | SMALLINT     | Code indicating the data type of the column:<br><br>0 = CHAR<br>1 = SMALLINT<br>2 = INTEGER<br>3 = FLOAT<br>4 = SMALLFLOAT<br>5 = DECIMAL<br>6 = SERIAL <sup>1</sup><br>7 = DATE<br>8 = MONEY<br>9 = NULL<br>10 = DATETIME<br>11 = BYTE<br>12 = TEXT<br>13 = VARCHAR<br>14 = INTERVAL<br>15 = NCHAR<br>16 = NVARCHAR<br>17 = INT8<br>18 = SERIAL8 <sup>1</sup><br>19 = SET<br>20 = MULTiset<br>21 = LIST<br>22 = ROW (unnamed)<br>23 = COLLECTION<br>40 = LVARCHAR fixed-length opaque types <sup>2</sup><br>41 = BLOB, BOOLEAN, CLOB variable-length opaque types <sup>2</sup><br>43 = LVARCHAR (client-side only)<br>45 = BOOLEAN |

**Table 42. The SYSCOLUMNS table (continued)**

| Column             | Type  | Explanation  |
|--------------------|---|--|
|                    |   | 52 = BIGINT<br>53 = BIGSERIAL <sup>1</sup><br>2061 = IDSSECURITYLABEL <sup>2,3</sup><br>4118 = ROW (named)   |
| <b>collength</b>   | Any of the following data types: <ul style="list-style-type: none"> <li>• Integer-based</li> <li>• Varying-length character</li> <li>• Time</li> <li>• Fixed-point</li> <li>• Simple-large-object</li> <li>• <a href="#">IDSSECURITYLABEL on page 1640</a></li> </ul> | The value depends on the data type of the column. For some data types, the value is the column length (in bytes). See <a href="#">Storing Column Length on page 1572</a> for more information.   |
| <b>colmin</b>      | INTEGER   | Holds the second-smallest value in a column  |
| <b>colmax</b>      | INTEGER   | Holds the second-largest value in a column   |
| <b>extended_id</b> | INTEGER   | Data type code, from the <b>sysxdtypes</b> table, of the data type specified in the <b>coltype</b> column  |
| <b>seclabelid</b>  | INTEGER   | The label ID of the security label associated with the column if it is a protected column. NULL otherwise.   |
| <b>colattr</b>     | SMALLINT  | <p><b>HIDDEN</b></p> <p>1 - Hidden column</p> <p><b>ROWVER</b></p> <p>2 - Row version column</p> <p><b>ROW_CHKSUM</b></p> <p>4 - Row key column</p> <p><b>ER_CHECKVER</b></p> <p>8 - ER row version column</p> <p><b>UPGRD1_COL</b></p> <p>16 - ER auto primary key column</p> <p><b>UPGRD2_COL</b></p> <p>32 - ER auto primary key column</p> <p><b>UPGRD3_COL</b></p> <p>64 - ER auto primary key column</p> |

**Table 42. The SYSCOLUMNS table (continued)**

| Column | Type | Explanation                   |
|--------|------|-------------------------------|
|        |      | <b>PK_NOTNULL</b>             |
|        |      | 128 - NOT NULL by PRIMARY KEY |

**Note:**

<sup>1</sup> In DB-Access, an offset value of 256 is always added to these **coltype** codes because DB-Access sets SERIAL, SERIAL8, and BIGSERIAL columns to NOT NULL.

<sup>2</sup> The built-in opaque data types do not have a unique **coltype** value. They are distinguished by the **extended\_id** column in the [SYSXTDTYPES](#) on page 1619 system catalog table.

<sup>3</sup> DISTINCT OF VARCHAR(128).

A composite index on **tabid** and **colno** allows only unique values.

The **coltype** codes can be incremented by bitmaps showing the following features of the column.

| Bit Value | Significance When Bit Is Set                   |
|-----------|--|
| 0x0100    | NULL values are not allowed                    |
| 0x0200    | Value is from a host variable                  |
| 0x0400    | Float-to-decimal for networked database server |
| 0x0800    | DISTINCT data type                             |
| 0x1000    | Named ROW type                                 |
| 0x2000    | DISTINCT type from LVARCHAR base type          |
| 0x4000    | DISTINCT type from BOOLEAN base type           |
| 0x8000    | Collection is processed on client system       |

For example, the **coltype** value 4118 for named row types is the decimal representation of the hexadecimal value 0x1016, which is the same as the hexadecimal **coltype** value for an unnamed row type (0x016), with the named-row-type bit set. The file `$INFORMIXDIR/incl/esql/sqltypes.h` contains additional information about **syscolumns.coltype** codes.

The following table lists the **coltype** values for the built-in opaque data types:

**NOT NULL constraints**

Similarly, the **coltype** value is incremented by 256 if the column does not allow NULL values. To determine the data type for such columns, subtract 256 from the value and evaluate the remainder, based on the possible **coltype** values. For example, if the **coltype** value is 262, subtracting 256 leaves a remainder of 6, indicating that the column has a SERIAL data type.

## Storing the column data type

The database server stores the **coltype** value as bitmap, as listed in [SYSCOLUMNS on page 1568](#).

## Storing column length

The **collength** column value depends on the data type of the column.

### Integer-based data types

A **collength** value for a BIGINT, BIGSERIAL, DATE, INTEGER, INT8, SERIAL, SERIAL8, or SMALLINT column is machine-independent. The database server uses the following lengths for these integer-based data types of the SQL language.

| Integer-based data types  | Length (in bytes) |
|---------------------------|-------------------|
| SMALLINT                  | 2                 |
| DATE, INTEGER, and SERIAL | 4                 |
| INT8 and SERIAL8          | 10                |
| BIGINT and BIGSERIAL      | 8                 |

### Varying-length character data types

For HCL Informix® columns of the LVARCHAR type, **collength** has the value of *max* from the data type declaration, or 2048 if no maximum was specified.

For VARCHAR or NVARCHAR columns, the *max\_size* and *min\_space* values are encoded in the **collength** column using one of these formulas:

- If the **collength** value is positive:

$$\text{collength} = (\text{min\_space} * 256) + \text{max\_size}$$

- If the **collength** value is negative:

$$\text{collength} + 65536 = (\text{min\_space} * 256) + \text{max\_size}$$

### Time data types

As noted previously, DATE columns have a value of 4 in the **collength** column.

For columns of type DATETIME or INTERVAL, **collength** is determined using the following formula:

$$(\text{length} * 256) + (\text{first\_qualifier} * 16) + \text{last\_qualifier}$$

The length is the physical length of the DATETIME or INTERVAL field, and *first\_qualifier* and *last\_qualifier* have values that the following table shows.

| Field qualifier | Value | Field qualifier | Value |
|-----------------|-------|-----------------|-------|
| YEAR            | 0     | FRACTION(1)     | 11    |

| Field qualifier | Value | Field qualifier | Value |
|-----------------|-------|-----------------|-------|
| MONTH           | 2     | FRACTION(2)     | 12    |
| DAY             | 4     | FRACTION(3)     | 13    |
| HOURL           | 6     | FRACTION(4)     | 14    |
| MINUTE          | 8     | FRACTION(5)     | 15    |
| SECOND          | 10    |                 |       |

For example, if a DATETIME YEAR TO MINUTE column has a length of 12 (such as YYYY:DD:MO:HH:MI), a *first\_qualifier* value of 0 (for YEAR), and a *last\_qualifier* value of 8 (for MINUTE), then the **collength** value is 3080 (from  $(256 * 12) + (0 * 16) + 8$ ).

### Fixed-point data types

The **collength** value for a MONEY or DECIMAL (*p*, *s*) column can be calculated using the following formula:

$$(precision * 256) + scale$$

### Simple-large-object data types

If the data type of the column is BYTE or TEXT, **collength** holds the length of the descriptor.

---

#### Related information

[Storing Maximum and Minimum Values on page 1573](#)

## Storing Maximum and Minimum Values

The **colmin** and **colmax** are statistical values which give the second-smallest and second-largest values of a column at the time of the last update statistics. These values will be determined by update statistics for leading index columns only. For example, if the values in an indexed column are 1, 2, 3, 4, and 5, the **colmin** value is 2 and the **colmax** value is 4. Storing the second-smallest and second-largest data values lets the query optimizer make assumptions about the range of values in the column and, in turn, further refine search strategies.

The **colmin** and **colmax** columns contain values only if the column is indexed and the UPDATE STATISTICS statement has explicitly or implicitly calculated the column distribution. If you store BYTE or TEXT data in the tblspace, the **colmin** value is encoded as -1.

The **colmin** and **colmax** columns are valid only for data types that fit into four bytes: SMALLFLOAT, SMALLINT, INTEGER, and the first four bytes of CHAR. The values for all other noninteger column types are the initial four bytes of the maximum or minimum value, which are treated as integers.

It is better to use UPDATE STATISTICS MEDIUM than to depend on **colmin** and **colmax** values. UPDATE STATISTICS MEDIUM gives better information and is valid for all data types.

HCL Informix® does not calculate **colmin** and **colmax** values for user-defined data types. These columns, however, have values for user-defined data types if a user-defined secondary access method supplies them.

---

## SYSCONSTRAINTS

The **sysconstraints** system catalog table lists the constraints placed on the columns in each database table. An entry is also placed in the **sysindexes** system catalog table (or **sysindices** view for HCL Informix®) for each unique, primary key, or referential constraint that does not already have a corresponding entry in **sysindexes** or **sysindices**. Because indexes can be shared, more than one constraint can be associated with an index. The **sysconstraints** table has the following columns.

**Table 43. SYSCONSTRAINTS table column descriptions**

| Column            | Type         | Explanation   |
|-------------------|--------------|---|
| <b>constrid</b>   | SERIAL       | Code uniquely identifying the constraint  |
| <b>constrname</b> | VARCHAR(128) | Name of the constraint  |
| <b>owner</b>      | VARCHAR(32)  | Name of the owner of the constraint   |
| <b>tabid</b>      | INTEGER      | Code uniquely identifying the table   |
| <b>constrtype</b> | CHAR(1)      | Code identifying the constraint type: <ul style="list-style-type: none"> <li>• C = Check constraint</li> <li>• N = Not NULL</li> <li>• P = Primary key</li> <li>• R = Referential</li> <li>• T = Table</li> <li>• U = Unique</li> </ul> |
| <b>idxname</b>    | VARCHAR(128) | Name of index corresponding to constraint   |
| <b>collation</b>  | CHAR(32)     | Collating order at the time when the constraint was created.  |

A composite index on the **constrname** and **owner** columns allows only unique values. An index on the **tabid** column allows duplicate values, and an index on the **constrid** column allows only unique values.

For check constraints (where **constrtype** = c), the **idxname** is always NULL. Additional information about each check constraint is contained in the **syschecks** and **syscoldepend** system catalog tables.

## SYSDEFAULTS

The **sysdefaults** system catalog table lists the user-defined defaults that are placed on each column in the database. One row exists for each user-defined default value.

The **sysdefaults** table has the following columns:

**Table 44. SYSDEFAULTS table column descriptions**

| Column         | Type      | Explanation   |
|----------------|-----------|---|
| <b>tabid</b>   | INTEGER   | Code uniquely identifying a table. When the <b>class</b> column contains the code P, then the <b>tabid</b> column references a procedure ID not a table ID. |
| <b>colno</b>   | SMALLINT  | Code uniquely identifying a column.   |
| <b>type</b>    | CHAR(1)   | Code identifying the type of default value:<br><br>C = Current®<br>L = Literal value<br>N = NULL<br>S = Dbservername or Sitename<br>T = Today<br>U = User   |
| <b>default</b> | CHAR(256) | If <b>sysdefaults.type</b> = L, a literal default value.  |
| <b>class</b>   | CHAR(1)   | Code identifying what kind of column:<br><br>T = table<br>t = ROW type<br>P = procedure   |

If no default is specified explicitly in the CREATE TABLE or the ALTER TABLE statement, then no entry exists for that column in the **sysdefaults** table.

If you specify a literal for the default value, it is stored in the **default** column as ASCII text. If the literal value is not of one of the data types listed in the next paragraph, the **default** column consists of two parts. The first part is the 6-bit representation of the binary value of the default value structure. The second part is the default value in ASCII text. A blank space separates the two parts.

If the data type of the column is not CHAR, NCHAR, NVARCHAR, or VARCHAR, or (for HCL Informix®) BOOLEAN or LVARCHAR, a binary representation of the default value is encoded in the **default** column.

A composite index on the **tabid**, **colno**, and **class** columns allows only unique values.

## SYSDEPEND

The **sysdepend** system catalog table describes how each view or table depends on other views or tables. One row exists in this table for each dependency, so a view based on three tables has three rows. The **sysdepend** table has the following columns.

**Table 45. SYSDEPEND table column descriptions**

| Column        | Type    | Explanation   |
|---------------|---------|---|
| <b>btabid</b> | INTEGER | Code uniquely identifying the base table or view                                      |
| <b>btype</b>  | CHAR(1) | Base object type: T = Table V = View  |
| <b>dtabid</b> | INTEGER | Code uniquely identifying a dependent table or view                                   |
| <b>dtype</b>  | CHAR(1) | Code for the type of dependent object; currently, only view (V = View) is implemented |

The **btabid** and **dtabid** columns are indexed and allow duplicate values.

## SYSDIRECTIVES

The **sysdirectives** table stores external optimizer directives that can be applied to queries. Whether queries in client applications can use these optimizer directives depends on the setting of the **IFX\_EXTDIRECTIVES** environment variable on the client system, as described in Chapter 3, and on the **EXT\_DIRECTIVES** setting in the configuration file of the database server.

The **sysdirectives** table has the following columns:

**Table 46. SYSDIRECTIVES table column descriptions**

| Column                | Type     | Explanation  |
|-----------------------|----------|--|
| <b>id</b>             | SERIAL   | Unique code identifying the optimizer directive  |
| <b>query</b>          | TEXT     | Text of the query as it exists in the application                                      |
| <b>directives</b>     | TEXT     | Text of the optimizer directive, without comments                                      |
| <b>directive_code</b> | BYTE     | Encoded directive  |
| <b>active</b>         | SMALLINT | Integer code that identifies whether this entry is active ( = 1 ) or test only ( = 2 ) |
| <b>hash_code</b>      | SMALLINT | For internal use only  |

NULL values are not valid in the **query** column. There is a unique index on the **id** column.

## SYSDISTRIB

The **sysdistrib** system catalog table stores data-distribution information for the query optimizer to use. Data distributions provide detailed table and column information to the optimizer to improve the choice of execution paths of SELECT statements.

The **sysdistrib** table has the following columns.

**Table 47. SYSDISTRIB table column descriptions**

| Column                  | Type                         | Explanation   |
|-------------------------|------------------------------|---|
| <b>tabid</b>            | INTEGER                      | Code identifying the table from which data values were gathered   |
| <b>colno</b>            | SMALLINT                     | Column number in the source table   |
| <b>seqno</b>            | INTEGER                      | Ordinal number for multiple entries   |
| <b>constructed</b>      | DATETIME YEAR TO FRACTION(5) | Date when the data distribution was created   |
| <b>mode</b>             | CHAR(1)                      | Optimization level: M = Medium H = High   |
| <b>resolution</b>       | SMALLFLOAT                   | Specified in the UPDATE STATISTICS statement  |
| <b>confidence</b>       | SMALLFLOAT                   | Specified in the UPDATE STATISTICS statement  |
| <b>encdat</b>           | STAT                         | Statistics information  |
| <b>type</b>             | CHAR(1)                      | Type of statistics: A = <b>encdat</b> has ASCII-encoded histogram in fixed-length character field S = <b>encdat</b> has user-defined statistics   |
| <b>smpsize</b>          | SMALLFLOAT                   | A value greater than zero up to 1.0 indicating a proportion of the total rows in the table that UPDATE STATISTICS samples. Values greater than 1.0 indicate the actual number of rows used that UPDATE STATISTICS samples. A value of zero indicates that no sample size is specified. UPDATE STATISTICS HIGH always updates statistics for all rows. |
| <b>rowssmpld</b>        | FLOAT                        | Number of rows in the sample  |
| <b>constr_time</b>      | DATETIME YEAR TO FRACTION(5) | Time when the distribution was recorded   |
| <b>ustnrows</b>         | FLOAT                        | Rows in fragment when distribution was calculated.  |
| <b>ustbuildduration</b> | INTERVAL HOUR TO FRACTION(5) | Time spent calculating the distribution statistics for this column  |

**Table 47. SYSDISTRIB table column descriptions (continued)**

| Column          | Type  | Explanation                    |
|-----------------|-------|--------------------------------|
| <b>nupdates</b> | FLOAT | Number of updates to the table |
| <b>ndeletes</b> | FLOAT | Number of deletes to the table |
| <b>ninserts</b> | FLOAT | Number of inserts to the table |

Information is stored in the **sysdistrib** table when an UPDATE STATISTICS statement with mode MEDIUM or HIGH is executed for a table. (UPDATE STATISTICS LOW does not insert a value into the **mode** column.)

Only user **informix** can select the **encdat** column.

Each row in the **sysdistrib** system catalog table is keyed by the **tabid** and **colno** for which the statistics are collected.

For built-in data type columns, the **type** field is set to **A**. The **encdat** column stores an ASCII-encoded histogram that is broken down into multiple rows, each of which contains 256 bytes.

In HCL Informix®, for columns of user-defined data types, the **type** field is set to **S**. The **encdat** column stores the statistics collected by the **statcollect** user-defined routine in multirepresentational form. Only one row is stored for each **tabid** and **colno** pair. A composite index on the **tabid**, **colno**, and **seqno** columns requires unique combinations of values.

The following three DML counter columns record counts of how many DML operations modifying data rows were performed on the table at the time of generation of column distribution statistics:

- UPDATE operations in **nupdates**
- DELETE operations in **ndeletes**
- and INSERT operations in **ninserts**

These counts can also include rows modified by MERGE statements.

These DML counter columns store the values of the counters from the server partition that exists when distribution statistics are generated. If the AUTO\_STAT\_MODE configuration parameter, or the AUTO\_STAT\_MODE session environment setting, or the AUTO keyword of the UPDATE STATISTICS statement has enabled selective updating of data distribution statistics, the **ninserts**, **ndeletes**, and **ninserts** values can affect whether UPDATE STATISTICS operations refresh existing data distribution statistics. When the UPDATE STATISTICS statement runs in MEDIUM or HIGH mode against the table, the database server compares the stored values in these columns with the current values in the partition. Column distribution statistics for the table are not updated if the sum of the stored values differs from the sum of these current **sysdistrib** DML counter values from the partition page by less than the threshold specified by the setting of the STATCHANGE table attribute or of the STATCHANGE configuration parameter.

## SYSDOMAINS

The **sysdomains** view is not used. It displays columns of other system catalog tables. It has the following columns.

**Table 48. SYSDOMAINS table column descriptions**

| Column       | Type          | Explanation                         |
|--------------|---------------|-------------------------------------|
| <b>id</b>    | SERIAL        | Unique code identifying the domain  |
| <b>owner</b> | CHAR(32)      | Name of the owner of the domain     |
| <b>name</b>  | VARCHAR(128 ) | Name of the domain                  |
| <b>type</b>  | SMALLINT      | Code identifying the type of domain |

There is no index on this view.

## SYSERRORS

The **syserrors** system catalog table stores information about error, warning, and informational messages returned by DataBlade® modules and user-defined routines using the **mi\_db\_error\_raise()** DataBlade® API function.

For a description of an error message, use the finderr utility.

The **syserrors** table has the following columns.

| Column          | Type         | Explanation   |
|-----------------|--------------|---|
| <b>sqlstate</b> | CHAR(5)      | SQLSTATE value associated with the error.   |
| <b>locale</b>   | CHAR(36)     | The locale with which this version of the message is associated (for example, <b>en_us.8859-1</b> ) |
| <b>level</b>    | SMALLINT     | Reserved for future use   |
| <b>seqno</b>    | SMALLINT     | Reserved for future use   |
| <b>message</b>  | VARCHAR(255) | Message text  |

To create a new message, insert a row directly into the **syserrors** table. By default, all users can view this table, but only users with the DBA privilege can modify it.

A composite index on the **sqlstate**, **locale**, **level**, and **seqno** columns allows only unique values.

## SYSEXTCOLS

The **sysextcols** system catalog table contains a row that describes each of the internal columns in external table **tabid** of format type (**fmttype**) FIXED.

The **sysextcols** table has the following columns.

| Column           | Type           | Explanation   |
|------------------|----------------|---|
| <b>tabid</b>     | INTEGER        | Unique identifying code of a table                    |
| <b>colno</b>     | SMALLINT       | Code identifying the column                           |
| <b>exttype</b>   | SMALLINT       | Code identifying an external column type              |
| <b>extstart</b>  | SMALLINT       | Starting position of column in the external data file |
| <b>extlength</b> | SMALLINT       | External column length (in bytes)                     |
| <b>nullstr</b>   | CHAR(256)      | Represents NULL in external data                      |
| <b>decprec</b>   | SMALLINT       | Precision for external decimals                       |
| <b>extstype</b>  | VARCHAR(128,0) | External type name                                    |

No entries are stored in **sysextcols** for DELIMITED or HCL Informix® format external files.

You can use the DBSCHEMA utility to write out the description of the external tables. To query these system catalog tables about an external table, use the **tabid** as stored in **systables** with **tabtype** = 'E'.

An index on the **tabid** column allows duplicate values.

## SYSEXTDFILES

The **sysextfiles** system catalog table contains identifying codes and the paths of external tables.

For each external table, at least one row exists in the **sysextfiles** system catalog table, which has the following columns.

| Column         | Type      | Explanation                                  |
|----------------|-----------|--|
| <b>tabid</b>   | INTEGER   | Unique identifying code of an external table |
| <b>dfentry</b> | CHAR(469) | Absolute source or target file path          |
| <b>blobdir</b> | CHAR(344) | Absolute or relative directory name          |
| <b>clobdir</b> | CHAR(344) | Absolute or relative directory name          |

You can use DBSCHEMA to write out the description of the external tables. To query these system catalog tables about an external table, use the **tabid** as stored in **systables** with **tabtype** = 'E'.

An index on the **tabid** column allows duplicate values.

## SYSEXTERNAL

For each external table, a single row exists in the **sysexternal** system catalog table.

The **tabid** column associates the external table record in this system catalog table with an entry in **systables**.

| Column            | Type         | Explanation   |
|-------------------|--------------|---|
| <b>tabid</b>      | INTEGER      | Unique identifying code of an external table                    |
| <b>fmttype</b>    | CHAR(1)      | Type of format: D = (delimited) F = (fixed) I = (HCL Informix®) |
| <b>codeset</b>    | VARCHAR(128) | Reserved for future use   |
| <b>recdelim</b>   | VARCHAR(128) | The record delimiter  |
| <b>flddelim</b>   | CHAR(4)      | The field delimiter   |
| <b>datefmt</b>    | CHAR(8)      | Reserved for future use   |
| <b>moneyfmt</b>   | CHAR(20)     | Reserved for future use   |
| <b>maxerrors</b>  | INTEGER      | Number of errors to allow                                       |
| <b>rejectfile</b> | CHAR(464)    | Name of the reject file   |
| <b>flags</b>      | INTEGER      | Optional <b>load</b> flags                                      |
| <b>ndfiles</b>    | INTEGER      | Number of data files in <b>sysextdfiles</b>                     |

You can use the **dbschema** utility to write out the description of the external tables. To query these system catalog tables about an external table, use the **tabid** as stored in **systables** with **tabtype = 'E'**.

An index on the **tabid** column allows only unique values.

## SYSFRAGAUTH

The **sysfragauth** system catalog table stores information about the privileges that are granted on table fragments. This table has the following columns.

**Table 49. SYSFRAGAUTH table column descriptions**

| Column         | Type     | Explanation                              |
|----------------|----------|--|
| <b>grantor</b> | CHAR(32) | Name of the grantor of privilege         |
| <b>grantee</b> | CHAR(32) | Name of the grantee of privilege         |
| <b>tabid</b>   | INTEGER  | Identifying code of the fragmented table |

**Table 49. SYSFRAGAUTH table column descriptions**

(continued)

| Column          | Type         | Explanation  |
|-----------------|--------------|--|
| <b>fragment</b> | VARCHAR(128) | Name of dbspace where fragment is stored   |
| <b>grauth</b>   | CHAR(6)      | A 6-byte pattern specifying fragment privileges (including 3 bytes reserved for future use): <ul style="list-style-type: none"> <li>• u or U = Update</li> <li>• i or I = Insert</li> <li>• d or D = Delete</li> </ul> |

In the **grauth** column, an uppercase code (such as **U** for Update) means that the grantee can grant the privilege to other users; a lowercase (for example, **u** for Update) means the user cannot grant the privilege to others. Hyphen (-) indicates the absence of the privilege for that position within the pattern.

A composite index on the **tabid**, **grantor**, **grantee**, and **fragment** columns allows only unique values. A composite index on the **tabid** and **grantee** columns allows duplicate values.

The following example displays the fragment-level privileges for one base table, as they exist in the **sysfragauth** table. In this example, the grantee **rajesh** can grant the Update, Delete, and Insert privileges to other users.

| grantor | grantee | tabid | fragment | fragauth |
|---------|---------|-------|----------|----------|
| dba     | omar    | 101   | dbsp1    | -ui--    |
| dba     | jane    | 101   | dbsp3    | --i--    |
| dba     | maria   | 101   | dbsp4    | --id--   |
| dba     | rajesh  | 101   | dbsp2    | -UID--   |

## SYSFRAGDIST

The **sysfragdist** system catalog table stores fragment-level column statistics for fragmented tables and indexes. One row exists for each table fragment or index fragment.

Only columns in fragmented tables are described here. (For table-level column statistics, see the **sysdistrib** system catalog table.)

The **sysfragdist** table has the following columns.

| Column       | Type    | Explanation   |
|--------------|---------|---|
| <b>tabid</b> | INTEGER | Unique identifying code of table (= <b>sysables.tabid</b> ) |

| Column                  | Type                         | Explanation   |
|-------------------------|------------------------------|---|
| <b>fragid</b>           | INTEGER                      | Unique identifying code of fragment ( = <b>sysfragments.partnum</b> )                           |
| <b>colno</b>            | SMALLINT                     | Unique identifying code of column ( = <b>syscolumns.colno</b> )                                 |
| <b>seqno</b>            | SMALLINT                     | Sequence number (for distributions that span multiple rows)                                     |
| <b>mode</b>             | CHAR(1)                      | UPDATE STATISTICS mode (H = high, or M = medium)  |
| <b>resolution</b>       | SMALLFLOAT                   | Average percentage of the sample in each bin  |
| <b>confidence</b>       | SMALLFLOAT                   | Estimated likelihood that a MEDIUM mode sample value is equivalent to an exact HIGH mode result |
| <b>rowssampled</b>      | FLOAT                        | Number of rows in the sample  |
| <b>ustbuildduration</b> | INTERVAL HOUR TO FRACTION(5) | Time spent to calculate the distribution for this column  |
| <b>constr_time</b>      | DATETIME YEAR TO FRACTION(5) | Time when the distribution was recorded   |
| <b>ustnrows</b>         | FLOAT                        | Rows in fragment when distribution was calculated.  |
| <b>minibinsize</b>      | FLOAT                        | For internal use only   |
| <b>nupdates</b>         | FLOAT                        | Number of updates to the table  |
| <b>ndeletes</b>         | FLOAT                        | Number of deletes to the table  |
| <b>ninserts</b>         | FLOAT                        | Number of inserts to the table  |
| <b>version</b>          | INTEGER                      | Reserved for future use   |
| <b>dbsnum</b>           | INTEGER                      | Unique identifying code of sbpace where <b>encdist</b> is stored                                |
| <b>encdist</b>          | STAT                         | Encrypted fragment distribution   |

The set of rows with a given combination of **tabid**, **fragid**, and **colno** values identifies the column statistics for that fragment of a table. These statistics can span multiple rows by using the **seqno** column for sequence numbering.

The *mode*, *resolution* and *confidence* values that are specified in the UPDATE STATISTICS MEDIUM or HIGH statement that calculate the column statistics for the fragment are recorded in the **sysfragdist** columns of the same names. To use existing fragment statistics to build table statistics, these three parameters should not change between UPDATE STATISTICS statements that reference the fragments of the same table. The only exception to this is that H mode fragmented statistics can be used to build M mode table statistics.

Column distribution statistics for the fragment are stored in the column **encdist**. The **dbsnum** column stores the identifying code of the smart blob space where the **encdist** object describing this fragment is stored. By default, the SBSPACENAME configuration parameter setting is the identifier of the sbpace whose identifying code is in the **dbsnum** column.

The following three columns record counts of how many DML operations modifying data rows were performed on the fragment at the time of generation of column distribution statistics:

- UPDATE operations in **nupdates**
- DELETE operations in **ndeletes**
- and INSERT operations in **ninserts**

These counts can also include rows modified by MERGE statements.

These DML counter columns store the values of the counters from the server partition that existed when distribution statistics were generated. When UPDATE STATISTICS runs in MEDIUM or HIGH mode against the fragmented table with fragment level statistics, the database server compares the stored values in these columns with the current values in the partition.

When the AUTO\_STAT\_MODE configuration parameter, or the AUTO\_STAT\_MODE session environment setting, or the AUTO keyword of the UPDATE STATISTICS statement has enabled selective updating of data distribution statistics, the **ninserts**, **ndeletes**, and **ninserts** values can affect whether UPDATE STATISTICS operations refresh existing data distribution statistics for the fragment. Column statistics for the fragment corresponding to the row in the **sysfragdist** table are not updated if the sum of the stored values differs from the sum of these current DML counter values for the partition page by less than the threshold specified by the setting of the STATCHANGE table attribute or of the STATCHANGE configuration parameter.

## SYSFRAGMENTS

The **sysfragments** system catalog table stores fragmentation information and LOW mode statistical distributions for individual fragments of tables and indexes. One row exists for each table fragment or index fragment.

The **sysfragments** table has the following columns.

| Column           | Type         | Explanation   |
|------------------|--------------|---|
| <b>fragtype</b>  | CHAR(1)      | Code indicating the type of fragmented object: <ul style="list-style-type: none"> <li>• I = Original index fragment</li> <li>• T = Original table fragment</li> </ul>   |
| <b>tabid</b>     | INTEGER      | Unique identifying code of table  |
| <b>indexname</b> | VARCHAR(128) | Name of index   |
| <b>colno</b>     | INTEGER      | Identifying code of TEXT or BYTE column, or the upper limit on the number of rolling window fragments   |
| <b>partn</b>     | INTEGER      | Identifying code of physical storage location   |
| <b>strategy</b>  | CHAR(1)      | Code for type of fragment distribution strategy: <ul style="list-style-type: none"> <li>• R = Round-robin distribution strategy</li> <li>• E = Expression-based distribution strategy</li> <li>• I = IN DBSPACE clause specifies a storage location as part of distribution strategy</li> </ul> |

| Column            | Type         | Explanation  |
|-------------------|--------------|--|
|                   |              | <ul style="list-style-type: none"> <li>• N = raNge-iNterval (or rolliNg wiNdown) distribution strategy</li> <li>• L = List distribution strategy</li> <li>• T = Table-based distribution strategy</li> <li>• H = table is a subtable within a table Hierarchy</li> </ul>   |
| <b>location</b>   | CHAR(1)      | Reserved for future use; shows L for local   |
| <b>servername</b> | VARCHAR(128) | Reserved for future use  |
| <b>evalpos</b>    | INTEGER      | <p>Position of fragment in the fragmentation list.</p> <p>For fragmentation by INTERVAL, one of the following values that indicates the type of information in the <b>exprtext</b> field:</p> <ul style="list-style-type: none"> <li>• -1 = List of dbspaces for interval fragments</li> <li>• -2 = Interval value</li> <li>• -3 = Fragmentation key</li> <li>• -4 = Rolling window fragment</li> </ul> <p>Fragmentation by LIST also uses the -3 value.</p> |
| <b>exprtext</b>   | TEXT         | <p>Expression for fragmentation strategy</p> <p>For fragmentation by INTERVAL, LIST, or rolling window, provides the information corresponding to the value of the <b>evalpos</b> field.</p>   |
| <b>exprbin</b>    | BYTE         | Binary version of expression   |
| <b>exprarr</b>    | BYTE         | Range-partitioning data to optimize expression in range-expression fragmentation strategy  |
| <b>flags</b>      | INTEGER      | Used internally  |
| <b>dbspace</b>    | VARCHAR(128) | Name of dbspace storing this fragment  |
| <b>levels</b>     | SMALLINT     | Number of B-tree index levels  |
| <b>npused</b>     | FLOAT        | <p>For table-fragmentation strategies: the number of data pages</p> <p>For index-fragmentation strategies: the number of leaf pages</p> <p>For rolling window tables: the units for the storage size limit in nrows</p>  |
| <b>nrows</b>      | FLOAT        | <p>For tables: the number of rows in the fragment.</p> <p>For indexes: the number of unique keys.</p> <p>For rolling window tables: the upper limit on storage size in the purge policy.</p>   |
| <b>clust</b>      | FLOAT        | Degree of index clustering; smaller numbers correspond to greater clustering.  |

| Column           | Type         | Explanation  |
|------------------|--------------|--|
| <b>partition</b> | VARCHAR(128) | Fragment name. This can match the name of the dbspace that stores the fragment, or can be an arbitrary name. |
| <b>version</b>   | SMALLINT     | Number that increments when fragment statistics is updated   |
| <b>nupdates</b>  | FLOAT        | Number of updates to the fragment  |
| <b>ndeletes</b>  | FLOAT        | Number of deletes to the fragment  |
| <b>ninserts</b>  | FLOAT        | Number of inserts to the fragment  |

Every fragment has a row in this table. The **evalpos** and **evaltext** fields contain information about individual fragments.

Tables and indexes created with fragmentation by INTERVAL or LIST have additional rows containing information about the fragmentation strategy.

The **strategy** type `T` is used for attached indexes. (This is a fragmented index whose fragmentation strategy is the same as for the table fragmentation.)

For information about the **nupdates**, **ndeletes**, and **ninserts** columns, which in **sysfragments** tabulate DML operations on a table since the most recent recalculation of its distribution statistics, see the description of the three columns that have the same names in the [SYSDISTRIB on page 1576](#) system catalog table.

In Informix®, a composite index on the **fragtype**, **tabid**, **indexname**, and **evalpos** columns allows duplicate values.

## SYSINDEXES

The **sysindexes** table is a view on the **sysindices** table. It contains one row for each index in the database.

The **sysindexes** table has the following columns.

**Table 50. SYSINDEXES table column descriptions**

| Column         | Type         | Explanation   |
|----------------|--------------|---|
| <b>idxname</b> | VARCHAR(128) | Index name  |
| <b>owner</b>   | VARCHAR(32)  | Owner of index (user <b>informix</b> for system catalog tables and <i>username</i> for database tables) |
| <b>tabid</b>   | INTEGER      | Unique identifying code of table  |
| <b>idxtype</b> | CHAR(1)      | Index type:   |

U = Unique

D = Duplicates allowed

G = Nonbitmap generalized-key index

**Table 50. SYSINDEXES table column descriptions**

(continued)

| Column           | Type     | Explanation  |
|------------------|----------|--|
|                  |          | g = Bitmap generalized-key index<br>u = unique, bitmap<br>d = nonunique, bitmap            |
| <b>clustered</b> | CHAR(1)  | Clustered or nonclustered index (C = Clustered)  |
| <b>part1</b>     | SMALLINT | Column number ( <b>colno</b> ) of a single index or the 1st component of a composite index |
| <b>part2</b>     | SMALLINT | 2nd component of a composite index   |
| <b>part3</b>     | SMALLINT | 3rd component of a composite index   |
| <b>part4</b>     | SMALLINT | 4th component of a composite index   |
| <b>part5</b>     | SMALLINT | 5th component of a composite index   |
| <b>part6</b>     | SMALLINT | 6th component of a composite index   |
| <b>part7</b>     | SMALLINT | 7th component of a composite index   |
| <b>part8</b>     | SMALLINT | 8th component of a composite index   |
| <b>part9</b>     | SMALLINT | 9th component of a composite index   |
| <b>part10</b>    | SMALLINT | 10th component of a composite index  |
| <b>part11</b>    | SMALLINT | 11th component of a composite index  |
| <b>part12</b>    | SMALLINT | 12th component of a composite index  |
| <b>part13</b>    | SMALLINT | 13th component of a composite index  |
| <b>part14</b>    | SMALLINT | 14th component of a composite index  |
| <b>part15</b>    | SMALLINT | 15th component of a composite index  |
| <b>part16</b>    | SMALLINT | 16th component of a composite index  |
| <b>levels</b>    | SMALLINT | Number of B-tree levels  |
| <b>leaves</b>    | INTEGER  | Number of leaves   |
| <b>nunique</b>   | INTEGER  | Number of unique keys in the first column  |
| <b>clust</b>     | INTEGER  | Degree of clustering; smaller numbers correspond to greater clustering                     |
| <b>idxflags</b>  | INTEGER  | Bitmap storing the current locking mode of the index                                       |

As with most system catalog tables, changes that affect existing indexes are reflected in this table only after you run the UPDATE STATISTICS statement.

Each **part1** through **part16** column in this table holds the column number (**colno**) of one of the 16 possible parts of a composite index. If the component is ordered in descending order, the **colno** is entered as a negative value. The columns are filled in for B-tree indexes that do not use user-defined data types or functional indexes. For generic B-trees and all other access methods, the **part1** through **part16** columns all contain zeros.

The **clust** column is blank until the UPDATE STATISTICS statement is run on the table. The maximum value is the number of rows in the table, and the minimum value is the number of data pages in the table.

## SYSINDICES

The **sysindices** system catalog table describes the indexes in the database. It stores LOW mode statistics for all indexes, and contains one row for each index that is defined in the database.

**Table 51. sysindices system catalog table columns**

| Column           | Type        | Explanation   |
|------------------|-------------|---|
| <b>idxname</b>   | VARCHAR(28) | Name of index   |
| <b>owner</b>     | VARCHAR(32) | Name of owner of index (user <b>informix</b> for system catalog tables and <i>username</i> for database tables)   |
| <b>tabid</b>     | INTEGER     | Unique identifying code of table  |
| <b>idxtype</b>   | CHAR(1)     | Uniqueness status<br>U = Unique values required<br>D = Duplicates allowed   |
| <b>clustered</b> | CHAR(1)     | Clustered or nonclustered status (C = Clustered)  |
| <b>levels</b>    | SMALLINT    | Number of tree levels   |
| <b>leaves</b>    | FLOAT       | Number of leaves  |
| <b>unique</b>    | FLOAT       | Number of unique keys in the first column   |
| <b>clust</b>     | FLOAT       | Degree of clustering; smaller numbers correspond to greater clustering. The maximum value is the number of rows in the table, and the minimum value is the number of data pages in the table. This column is blank until UPDATE STATISTICS is run on the table. |

Table 51. sysindices system catalog table columns

(continued)

| Column             | Type                         | Explanation   |
|--------------------|------------------------------|---|
| <b>nrows</b>       | FLOAT                        | Estimated number of rows in the table (zero until UPDATE STATISTICS is run on the table)  |
| <b>index keys</b>  | INDEXKEYARRAY                | Internal representation of the index keys. Column can have up to three fields, in the format: <b>procid</b> , ( <i>col1,col2,...,coln</i> ), <b>opclassid</b> where $1 < n < 341$ |
| <b>amid</b>        | INTEGER                      | Unique identifying code of the access method that implements this index. (Value = <b>am_id</b> for that access method in the <b>sysams</b> table.)                                |
| <b>aram</b>        | LVARCHAR(2048)               | List of parameters used to customize the <b>amid</b> access method behavior   |
| <b>collation</b>   | CHAR(32)                     | Database locale whose collating order was in effect at the time of index creation   |
| <b>page size</b>   | INTEGER                      | Size of the page, in bytes, where this index is stored  |
| <b>nhashcols</b>   | SMALLINT                     | Number of hashed columns in a FOT index   |
| <b>nbuckets</b>    | SMALLINT                     | Number of subtrees (buckets) in a forest of trees (FOT) index   |
| <b>ustlastwts</b>  | DATETIME YEAR TO FRACTION    | Date and time when index statistics were last recorded  |
| <b>usttime</b>     | INTERVAL HOUR TO FRACTION(5) | Time required to calculate index statistics   |
| <b>nupdates</b>    | FLOAT                        | Number of updates to the table  |
| <b>ndeletes</b>    | FLOAT                        | Number of deletes to the table  |
| <b>ninserts</b>    | FLOAT                        | Number of inserts to the table  |
| <b>firstextent</b> | INT                          | Size (in KB) of the first extent of the index   |

**Table 51. sysindices system catalog table columns**

(continued)

| Column           | Type           | Explanation   |
|------------------|----------------|---|
| <b>nextsize</b>  | INT            | Size (in KB) of the next extent of the index  |
| <b>indexattr</b> | INT            | <ul style="list-style-type: none"> <li>• 0x00000001 = The index has a partial column key</li> <li>• 0x00000002 = The index is compressed</li> <li>• 0x00000004 = The index is on a BSON column</li> </ul> |
| <b>jparam</b>    | LVARCHAR(2048) | BSON index information  |

**Tip:** This system catalog table is changed from Version 7.2 of HCL Informix®. The earlier schema of this system catalog table is still available as a view that can be accessed under its original name: **sysindexes**. See [SYSINDEXES on page 1586](#).

Changes that affect existing indexes are reflected in this system catalog table only after you run the UPDATE STATISTICS statement.

The fields within the **indexkeys** columns have the following significance:

- The **procid** (as in **sysprocedures**) exists only for a functional index on return values of a function defined on columns of the table.
- The list of columns (*col1, col2, ... , coln*) in the second field identifies the columns on which the index is defined. The maximum is language-dependent: up to 341 for an SPL or Java™ UDR; up to 102 for a C UDR.
- The **opclassid** identifies the secondary access method that the database server used to build and to search the index. This is the same as the **sysopclasses.opclassid** value for the access method.

For information about the **nupdates**, **ndeletes**, and **ninserts** columns, which in **sysindices** tabulate DML operations on an index since the most recent recalculation of its distribution statistics, see the description of the three columns that have the same names in the [SYSDISTRIB on page 1576](#) system catalog table.

The **fextsize** column shows the user-defined first extent size (in kilobytes) that the optional EXTENT SIZE clause specified in the CREATE INDEX statement that defined the index. Similarly, the **nextsize** column shows the user-defined next extent size (in kilobytes) that the optional NEXT SIZE clause specified in the CREATE INDEX statement. Each of these columns displays a value of zero (0) if the corresponding EXTENT SIZE or NEXT SIZE clause was omitted when the index was created.

If the CREATE INDEX statement that defines a new index includes no explicit extent size specifications, the database server automatically calculates the first and next extent sizes, but the **fextsize** and **nextsize** column values are set to 0. When the database server is converted from a release earlier than Version 11.70, the **fextsize** and **nextsize** values for every migrated index are 0.

The **tabid** column is indexed and allows duplicate values. A composite index on the **idxname**, **owner**, and **tabid** columns allows only unique values.

## SYSINHERITS

The **sysinherits** system catalog table stores information about table hierarchies and named ROW type inheritance. Every supertype, subtype, supertable, and subtable in the database has a corresponding row in the **sysinherits** table.

| Column        | Type    | Explanation   |
|---------------|---------|---|
| <b>child</b>  | INTEGER | Identifying code of the subtable or subtype                   |
| <b>parent</b> | INTEGER | Identifying code of the supertable or supertype               |
| <b>class</b>  | CHAR(1) | Inheritance class: <b>t</b> = named ROW type <b>T</b> = table |

The **child** and **parent** values are from **sysxdtypes.extended\_id** for named ROW types, or from **sys.tables.tabid** for tables. Simple indexes on the **child** and **parent** columns allow duplicate values.

## SYSLANGAUTH

The **syslangauth** system catalog table contains the authorization information about computer languages that are used to write user-defined routines (UDRs).

**Table 52. SYSLANGAUTH table column descriptions**

| Column          | Type        | Explanation  |
|-----------------|-------------|--|
| <b>grantor</b>  | VARCHAR(32) | Name of the grantor of the language authorization<br>)   |
| <b>grantee</b>  | VARCHAR(32) | Name of the grantee of the language authorization<br>)   |
| <b>langid</b>   | INTEGER     | Identifying code of language in <b>sysroutinelangs</b> table   |
| <b>langauth</b> | CHAR(1)     | The language authorization:<br><br>u = Usage privilege granted<br>U = Usage privilege granted WITH GRANT<br>OPTION |

A composite index on the **langid**, **grantor**, and **grantee** columns allows only unique values. A composite index on the **langid** and **grantee** columns allows duplicate values.

## SYSLOGMAP

The **syslogmap** system catalog table contains fragmentation information.

**Table 53. SYSLOGMAP table column descriptions**

| Column        | Type    | Explanation  |
|---------------|---------|--|
| <b>tabloc</b> | INTEGER | Code for the location of a table in another database |
| <b>tabid</b>  | INTEGER | Unique identifying code of the table                 |
| <b>fragid</b> | INTEGER | Identifying code of the fragment                     |
| <b>flags</b>  | INTEGER | Bitmap of modifiers from declaration of fragment     |

A simple index on the **tabloc** column and a composite index on the **tabid** and **fragid** columns do not allow duplicate values.

## SYSOBJSTATE

The **sysobjstate** system catalog table stores information about the state (object mode) of database objects. The types of database objects that are listed in this table are indexes, triggers, and constraints.

Every index, trigger, and constraint in the database has a corresponding row in the **sysobjstate** table if a user creates the object. Indexes that the database server creates on the system catalog tables are not listed in the **sysobjstate** table because their object mode cannot be changed.

The **sysobjstate** table has the following columns.

**Table 54. SYSOBJSTATE table column descriptions**

| Column         | Type         | Explanation   |
|----------------|--------------|---|
| <b>objtype</b> | CHAR(1)      | Code for the type of database object:<br><ul style="list-style-type: none"> <li>• C = Constraint</li> <li>• I = Index</li> <li>• T = Trigger</li> </ul> |
| <b>owner</b>   | VARCHAR(32)  | Authorization identifier of the owner of the database object  |
| <b>name</b>    | VARCHAR(128) | Name of the database object   |

**Table 54. SYSOBJSTATE table column descriptions**

(continued)

| Column       | Type    | Explanation   |
|--------------|---------|---|
| <b>tabid</b> | INTEGER | Identifying code of table on which the object is defined  |
| <b>state</b> | CHAR(1) | The current state (object mode) of the database object. This value can be one of the following codes: <ul style="list-style-type: none"> <li>• D = Disabled</li> <li>• E = Enabled</li> <li>• F = Filtering with no integrity-violation errors</li> <li>• G = Filtering with integrity-violation error</li> </ul> |

A composite index on the **objtype**, **name**, **owner**, and **tabid** columns allows only unique combinations of values. A simple index on the **tabid** column allows duplicate values.

## SYSOPCLASSES

The **sysopclasses** system catalog table contains information about operator classes associated with secondary access methods. It contains one row for each operator class that has been defined in the database. The **sysopclasses** table has the following columns.

| Column             | Type           | Explanation   |
|--------------------|----------------|---|
| <b>opclassname</b> | VARCHAR(128)   | Name of the operator class  |
| <b>owner</b>       | VARCHAR(32)    | Name of the owner of the operator class   |
| <b>amid</b>        | INTEGER        | Identifying code of the secondary access method associated with this operator class |
| <b>opclassid</b>   | SERIAL         | Identifying code of the operator class  |
| <b>ops</b>         | LVARCHAR(2048) | List of names of the operators that belong to this operator class                   |
| <b>support</b>     | LVARCHAR(2048) | List of names of support functions defined for this operator class                  |

The **opclassid** value corresponds to the **sysams.am\_defopclass** value that specifies the default operator class for the secondary access method that the **amid** column specifies.

The **sysopclasses** table has a composite index on the **opclassname** and **owner** columns and an index on **opclassid** column. Both indexes allow only unique values.

## SYSPROCAUTH

The **sysprocauth** system catalog table describes the privileges granted on a procedure or function. It contains one row for each set of privileges that is granted. The **sysprocauth** table has the following columns.

**Table 55. SYSPROCAUTH table column descriptions**

| Column          | Type        | Explanation  |
|-----------------|-------------|--|
| <b>grantor</b>  | VARCHAR(32) | Name of grantor of privileges to access the routine  |
| <b>grantee</b>  | VARCHAR(32) | Name of grantee of privileges to access the routine  |
| <b>procid</b>   | INTEGER     | Unique identifying code of the routine   |
| <b>procauth</b> | CHAR(1)     | Type of privilege granted on the routine:<br>e = Execute privilege on routine<br>E = Execute privilege WITH GRANT OPTION |

A composite index on the **procid**, **grantor**, and **grantee** columns allows only unique values. A composite index on the **procid** and **grantee** columns allows duplicate values.

## SYSPROCBODY

The **sysprocbody** system catalog table describes the compiled version of each procedure or function in the database. Because the **sysprocbody** table stores the text of the routine, each routine can have multiple rows. The **sysprocbody** table has the following columns.

**Table 56. SYSPROCBODY table column descriptions**

| Column         | Type    | Explanation  |
|----------------|---------|--|
| <b>procid</b>  | INTEGER | Unique identifying code for the routine  |
| <b>datakey</b> | CHAR(1) | Type of information in the <b>data</b> column:<br>A = Routine alter SQL (will not change this value after update statistics)<br>D = Routine user documentation text<br>E = Time of creation information<br>L = Literal value (that is, literal number or quoted string)<br>P = Interpreter instruction code (p-code)<br>R = Routine return value type list |

**Table 56. SYSPROCBODY table column descriptions (continued)**

| Column       | Type      | Explanation   |
|--------------|-----------|---|
|              |           | S = Routine symbol table<br>T = Routine text creation SQL |
| <b>seqno</b> | INTEGER   | Line number within the routine                            |
| <b>data</b>  | CHAR(256) | Actual text of the routine                                |

The A flag indicates the procedure modifiers are altered. ALTER ROUTINE statement updates only modifiers and not the routine body. UPDATE STATISTICS updates the query plan and not the routine modifiers, and the value of datakey will not be changed from A. The A flag marks all the procedures and functions that have altered modifiers, including overloaded procedures and functions. The T flag is used for routine creation text.

The **data** column contains actual data, which can be in one of these formats:

- Encoded return values list
- Encoded symbol table
- Literal data
- P-code for the routine
- Compiled code for the routine
- Text of the routine and its documentation

A composite index on the **procid**, **datakey**, and **seqno** columns allows only unique values.

## SYSPROCCOLUMNS

The **sysproccolumns** system catalog table stores information about return types and parameter names of all UDRs in SYSPROCEDURES.

A composite index on the **procid** and **paramid** columns in this table allows only unique values.

**Table 57. SYSPROCCOLUMNS table column descriptions**

| Column           | Type                   | Explanation                              |
|------------------|------------------------|--|
| <b>procid</b>    | INTEGER                | Unique identifying code of the routine   |
| <b>paramid</b>   | INTEGER                | Unique identifying code of the parameter |
| <b>paramname</b> | VARCHAR<br>(IDENTSIZE) | Name of the parameter                    |
| <b>paramtype</b> | SMALLINT               | Identifies the type of parameter         |
| <b>paramlen</b>  | SMALLINT               | Specifies the length of the parameter    |

**Table 57. SYSPROCCOLUMNS table column descriptions (continued)**

| Column           | Type    | Explanation  |
|------------------|---------|--|
| <b>paramxid</b>  | INTEGER | Specifies the extended type ID for the parameter   |
| <b>paramattr</b> | INTEGER | 0 = Parameter is of unknown type<br>1 = Parameter is INPUT mode<br>2 = Parameter is INOUT mode<br>3 = Parameter is multiple return value<br>4 = Parameter is OUT mode<br>5 = Parameter is a return value |

## SYS PROCEDURES

The **sysprocedures** system catalog table lists the characteristics for each function and procedure that is registered in the database. It contains one row for each routine.

Each function in **sysprocedures** has a unique value, **procid**, called a *routine identifier*. Throughout the system catalog, a function is identified by its routine identifier, not by its name.

The **sysprocedures** table has the following columns.

**Table 58. SYS PROCEDURES table column descriptions**

| Column          | Type         | Explanation   |
|-----------------|--------------|---|
| <b>procname</b> | VARCHAR(128) | Name of routine   |
| <b>owner</b>    | VARCHAR(32)  | Name of owner   |
| <b>procid</b>   | SERIAL       | Unique identifying code for the routine   |
| <b>mode</b>     | CHAR(1)      | Mode type:<br><br>D or d = DBA<br>O or o = Owner<br>P or p = Protected<br>R or r = Restricted<br>T or t = Trigger |
| <b>retsize</b>  | INTEGER      | Compiled size (in bytes) of returned values   |
| <b>symsize</b>  | INTEGER      | Compiled size (in bytes) of symbol table  |
| <b>datasize</b> | INTEGER      | Compiled size (in bytes) of constant data   |
| <b>codesize</b> | INTEGER      | Compiled size (in bytes) of routine code  |
| <b>numargs</b>  | INTEGER      | Number of arguments to routine  |
| <b>isproc</b>   | CHAR(1)      | Specifies if the routine is a procedure or a function:  |

Table 58. SYSPROCEDURES table column descriptions (continued)

| Column                | Type          | Explanation  |
|-----------------------|---------------|--|
|                       |               | <p>t = procedure</p> <p>f = function</p>   |
| <b>specificname</b>   | VARCHAR(128)  | Specific name for the routine  |
| <b>externalname</b>   | VARCHAR(255)  | Location of the external routine. This item is language-specific in content and format.  |
| <b>paramstyle</b>     | CHAR(1)       | Parameter style: i = HCL Informix®   |
| <b>langid</b>         | INTEGER       | Language code (in <b>sysroutinelangs</b> table)  |
| <b>paramtypes</b>     | RTNPARAMTYPES | Information describing the parameters of the routine   |
| <b>variant</b>        | BOOLEAN       | Whether the routine is VARIANT or not: <p>t = is VARIANT</p> <p>f = is not VARIANT</p>   |
| <b>client</b>         | BOOLEAN       | Reserved for future use  |
| <b>handlesnulls</b>   | BOOLEAN       | NULL handling indicator: <p>t = handles NULLs</p> <p>f = does not handle NULLs</p>   |
| <b>percallcost</b>    | INTEGER       | Amount of CPU per call<br>Integer cost to execute UDR: cost/call - 0 -(2^31-1)   |
| <b>commutator</b>     | VARCHAR(128)  | Name of commutator function  |
| <b>negator</b>        | VARCHAR(128)  | Name of the negator function   |
| <b>selfunc</b>        | VARCHAR(128)  | Name of function to estimate selectivity of the UDR  |
| <b>internal</b>       | BOOLEAN       | Specifies if the routine can be called from SQL: <p>t = routine is internal, not callable from SQL</p> <p>f = routine is external, callable from SQL</p> |
| <b>class</b>          | CHAR(18)      | CPU class by which the routine should be executed  |
| <b>stack</b>          | INTEGER       | Stack size in bytes required per invocation  |
| <b>parallelizable</b> | BOOLEAN       | Parallelization indicator for UDR: <p>t = parallelizable</p> <p>f = not parallelizable</p>   |

**Table 58. SYSPROCEDURES table column descriptions (continued)**

| Column           | Type         | Explanation  |
|------------------|--------------|--|
| <b>costfunc</b>  | VARCHAR(128) | Name of the cost function for the UDR                    |
| <b>selconst</b>  | SMALLFLOAT   | Selectivity constant for UDR                             |
| <b>procflags</b> | INTEGER      | For internal use only                                    |
| <b>collation</b> | CHAR(32)     | Collating order at the time when the routine was created |

In the **mode** column, the R mode is a special case of the O mode. A routine is in restricted (R) mode if it was created with a specified owner who is different from the routine creator. If routine statements involving a remote database are executed, the database server uses the access privileges of the user who executes the routine instead of the privileges of the routine owner. In all other scenarios, R-mode routines behave the same as O-mode routines.

The database server can create protected routines for internal use. The **sysprocedures** table identifies these protected routines with the letter **P** or **p** in the **mode** column, where **P** indicates an SPL routine. Protected routines have the following restrictions:

- You cannot use the ALTER FUNCTION, ALTER PROCEDURE, or ALTER ROUTINE statements to modify protected routines.
- You cannot use the DROP FUNCTION, DROP PROCEDURE, or DROP ROUTINE statements to unregister protected routines.
- You cannot use the dbschema utility to display protected routines.

In earlier versions, protected SPL routines were indicated by a lowercase **p**. Starting with version 9.0, protected SPL routines are treated as DBA routines and cannot be Owner routines. Thus **D** and **O** indicate DBA routines and Owner routines, while **d** and **o** indicate protected DBA routines and protected Owner routines.

The trigger mode designates user-defined SPL routines that can be invoked only from the FOR EACH ROW section of a triggered action.

**Important:** After you issue the SET SESSION AUTHORIZATION statement, the database server assigns a restricted mode to all Owner routines that you created while using the new identity.

A unique index is defined on the **procid** column. A composite index on the **procname**, **isproc**, **numargs**, and **owner** columns allows duplicate values, as does a composite index on the **specificname** and **owner** columns.

## SYSPROCPLAN

The **sysprocplan** system catalog table describes the query-execution plans and dependency lists for data-manipulation statements within each routine. Because different parts of a routine plan can be created on different dates, this table can contain multiple rows for each routine.

**Table 59. SYSPROCPLAN table column descriptions**

| Column          | Type      | Explanation  |
|-----------------|-----------|--|
| <b>procid</b>   | INTEGER   | Identifying code for the routine   |
| <b>planid</b>   | INTEGER   | Identifying code for the plan  |
| <b>datakey</b>  | CHAR(1)   | Type of information stored in <b>data</b> column:<br><br>D = Dependency list<br>I = Information record<br>Q = Execution plan |
| <b>seqno</b>    | INTEGER   | Line number within the plan  |
| <b>created</b>  | DATE      | Date when plan was created   |
| <b>datasize</b> | INTEGER   | Size (in bytes) of the list or plan  |
| <b>data</b>     | CHAR(256) | Encoded (compiled) list or plan  |

Before a routine is run, its dependency list in the **data** column is examined. If the major version number of a table accessed by the plan has changed, or if any object that the routine uses has been modified since the plan was optimized (for example, if an index has been dropped), then the plan is optimized again. When **datakey** is I, the **data** column stores information about UPDATE STATISTICS and PDQPRIORITY.

It is possible to delete all the plans for a given routine by using the DELETE statement on **sysprocplan**. When the routine is subsequently executed, new plans are automatically generated and recorded in **sysprocplan**. The UPDATE STATISTICS FOR PROCEDURE statement also updates this table.

A composite index on the **procid**, **planid**, **datakey**, and **seqno** columns allows only unique values.

## SYSREFERENCES

The **sysreferences** system catalog table lists all referential constraints on columns. It contains a row for each referential constraint in the database.

**Table 60. SYSREFERENCES table column descriptions**

| Column          | Type    | Explanation   |
|-----------------|---------|---|
| <b>constrid</b> | INTEGER | Code uniquely identifying the constraint              |
| <b>primary</b>  | INTEGER | Identifying code of the corresponding primary key     |
| <b>ptabid</b>   | INTEGER | Identifying code of the table that is the primary key |

**Table 60. SYSREFERENCES table column descriptions**

(continued)

| Column           | Type    | Explanation  |
|------------------|---------|--|
| <b>updrule</b>   | CHAR(1) | Reserved for future use; displays an R   |
| <b>delrule</b>   | CHAR(1) | Whether constraint uses cascading delete or restrict rule:<br><br>C = Cascading delete<br>R = Restrict (default) |
| <b>matchtype</b> | CHAR(1) | Reserved for future use; displays an N   |
| <b>pendant</b>   | CHAR(1) | Reserved for future use; displays an N   |

The **constrid** column is indexed and allows only unique values. The **primary** column is indexed and allows duplicate values.

## SYSROLEAUTH

The **sysroleauth** system catalog table describes the roles that are granted to users. It contains one row for each role that is granted to a user in the database. The **sysroleauth** table has the following columns.

**Table 61. SYSROLEAUTH table column descriptions**

| Column              | Type        | Explanation  |
|---------------------|-------------|--|
| <b>rolename</b>     | VARCHAR(32) | Name of the role<br>)  |
| <b>grantee</b>      | VARCHAR(32) | Name of the grantee of the role<br>)   |
| <b>is_grantable</b> | CHAR(1)     | Specifies whether the role is grantable:<br><br>Y = Grantable<br>N = Not grantable |

The **is\_grantable** column indicates whether the role was granted with the WITH GRANT OPTION of the GRANT statement.

A composite index on the **rolename** and **grantee** columns allows only unique values.

## SYSROUTINELANGS

The **sysroutinelangs** system catalog table lists the supported programming languages for user-defined routines (UDRs). It has these columns.

| Column              | Type         | Explanation                                      |
|---------------------|--------------|--|
| <b>langid</b>       | SERIAL       | Code uniquely identifying a supported language   |
| <b>langname</b>     | CHAR(30)     | Name of the language, such as C or SPL           |
| <b>langinitfunc</b> | VARCHAR(128) | Name of initialization function for the language |
| <b>langpath</b>     | CHAR(255)    | Directory path for the UDR language              |
| <b>langclass</b>    | CHAR(18)     | Name of the class of the UDR language            |

An index on the **langname** column allows duplicate values.

## SYSSECLABELAUTH

The **sysseclabelauth** system catalog table records the LBAC labels that have been granted to users. It has these columns.

| Column                 | Type     | Explanation  |
|------------------------|----------|--|
| <b>GRANTEE</b>         | CHAR(32) | The name of the label grantee  |
| <b>secpolicyid</b>     | INTEGER  | The ID of the security policy to which the security label belongs.   |
| <b>readseclabelid</b>  | INTEGER  | The security label ID of the security label granted for read access  |
| <b>writeseclabelid</b> | INTEGER  | The security label ID of the security label granted for write access |

## SYSSECLABELCOMPONENTS

The **sysseclabelcomponents** system catalog table records security label components. It has these columns.

| Column          | Type         | Explanation         |
|-----------------|--------------|---------------------|
| <b>compname</b> | VARCHAR(128) | Component name      |
| <b>compid</b>   | SERIAL       | Component ID        |
| <b>comptype</b> | CHAR(1)      | The component type: |

| Column              | Type         | Explanation   |
|---------------------|--------------|---|
|                     |              | A = array<br>S = set<br>T = tree                                      |
| <b>numelements</b>  | INTEGER      | Number of elements in the component                                   |
| <b>coveringinfo</b> | VARCHAR(128) | Internal encoding information   |
| <b>numalters</b>    | SMALLINT     | Numbers of alter operations that have been performed on the component |

## SYSSECLABELCOMPONENTELEMENTS

The **sysseclabelcomponentelements** system catalog table records the values of component elements of security labels. It has these columns.

| Column                 | Type        | Explanation   |
|------------------------|-------------|---|
| <b>compid</b>          | INTEGER     | Component ID  |
| <b>element</b>         | VARCHAR(32) | Element name  |
| <b>elementencoding</b> | CHAR(8)     | Encoded form of the element   |
| <b>parentelement</b>   | VARCHAR(32) | The name of the parent elements for tree components. The value is NULL for the following items:<br><br>Set components<br>Array components<br>Root nodes of a tree component |
| <b>alterversion</b>    | SMALLINT    | The number of the alter operation when the element is added. This value is used by the <b>dbexport</b> and <b>dbimport</b> commands.  |

## SYSSECLABELNAMES

The **sysseclabelnames** system catalog table records the security label names. It has these columns.

| Column              | Type         | Explanation  |
|---------------------|--------------|--|
| <b>secpolicyid</b>  | INTEGER      | The ID of the security policy to which the security label belongs. |
| <b>seclabelname</b> | VARCHAR(128) | The name of the security label                                     |

| Column            | Type    | Explanation                  |
|-------------------|---------|------------------------------|
| <b>seclabelid</b> | INTEGER | The ID of the security label |

## SYSSECLABELS

The **sysseclabels** system catalog table records the security label encoding. It has these columns.

| Column                  | Type         | Explanation   |
|-------------------------|--------------|---|
| <b>secpolicyid</b>      | INTEGER      | ID of the security policy to which the security label belongs |
| <b>seclabelid</b>       | INTEGER      | Security label ID   |
| <b>sysseclabelnames</b> | VARCHAR(128) | Security label encoding                                       |

## SYSSECPOLICIES

The **syssecpolicies** system catalog table records security policies. It has these columns.

| Column                  | Type         | Explanation  |
|-------------------------|--------------|--|
| <b>secpolicyname</b>    | VARCHAR(128) | Security policy name   |
| <b>secpolicyid</b>      | SERIAL       | Security policy ID   |
| <b>numcomps</b>         | SMALLINT     | Number of security label components in the security policy   |
| <b>comptypelist</b>     | CHAR(16)     | An ordered list of the type of each component in the policy.<br><br>A = array<br>S = set<br>T = tree<br>- = Beyond NUMCOMPS  |
| <b>overrideseclabel</b> | CHAR(1)      | Indicates the behavior when a user's security label and exemption credentials do not allow them to insert or update a data row with the security that is label provided on the INSERT or UPDATE SQL statement. |

| Column | Type | Explanation  |
|--------|------|--|
|        |      | <ul style="list-style-type: none"> <li>• Y: The security label provided is ignored and replaced by the user's security label for write access.</li> <li>• N: Return an error when not authorized to write a security label.</li> </ul> |

## SYSSECPOLICYCOMPONENTS

The **syssecpolicycomponents** system catalog table records the components for each security policies. It has these columns.

| Column             | Type     | Explanation   |
|--------------------|----------|---|
| <b>secpolicyid</b> | INTEGER  | Security policy ID  |
| <b>compid</b>      | INTEGER  | ID of a component of the label security policy  |
| <b>compno</b>      | SMALLINT | Position of the security label component as it exists in the security policy, starting with position 1. |

## SYSSECPOLICYEXEMPTIONS

The **syssecpolicyexemptions** system catalog table records the exemptions that have been given to users. It has these columns.

| Column             | Type     | Explanation  |
|--------------------|----------|--|
| <b>grantee</b>     | CHAR(32) | The user who has this exemption  |
| <b>secpolicyid</b> | INTEGER  | ID of the policy on which the exemption is granted   |
| <b>exemption</b>   | CHAR(6)  | <p>The exemption given to the user who is identified in the GRANTEE column. The six characters have the following meanings:</p> <ul style="list-style-type: none"> <li>1 = Read array</li> <li>2 = Read set</li> <li>3 = Read tree</li> <li>4 = Write array</li> <li>5 = Write set</li> <li>6 = Write tree</li> </ul> <p>Each character has one of the following values:</p> |

| Column | Type | Explanation  |
|--------|------|--|
|        |      | E = Exempt<br>D = Write down exemption<br>U = Write up exemption<br>- = No exemption |

## SYSSEQUENCES

The **syssequences** system catalog table lists the sequence objects that exist in the database. The **syssequences** table has the following columns.

| Column             | Type    | Explanation   |
|--------------------|---------|---|
| <b>seqid</b>       | SERIAL  | Code uniquely identifying the sequence object                       |
| <b>tabid</b>       | INTEGER | Identifying code of the sequence as a table object                  |
| <b>start_val</b>   | INT8    | Starting value of the sequence                                      |
| <b>inc_val</b>     | INT8    | Value of the increment between successive values                    |
| <b>max_val</b>     | INT8    | Largest possible value of the sequence                              |
| <b>min_val</b>     | INT8    | Smallest possible value of the sequence                             |
| <b>cycle</b>       | CHAR(1) | Zero means NOCYCLE, 1 means CYCLE                                   |
| <b>restart_val</b> | INT8    | Starting value of the sequence after ALTER SEQUENCE RESTART was run |
| <b>cache</b>       | INTEGER | Number of preallocated values in sequence cache                     |
| <b>order</b>       | CHAR(1) | Zero means NOORDER, 1 means ORDER                                   |

## SYSSURROGATEAUTH

The **sys surrogateauth** system catalog table stores trusted user and surrogate user information.

The **sys surrogateauth** system catalog table is populated when the GRANT SETSESSIONAUTH statement is run. Users or roles specified in the TO clause are added to **trusteduser** column. Users specified in the ON clause are added to **surrogateuser** column.

For example, consider the following statement:

```
GRANT SETSESSIONAUTH ON bill, john TO mary, peter;
```

Entries in the **sys surrogateauth** table are created as follows:

```

trusteduser  surrogateuser
mary         bill
mary         john
peter        bill
peter        john

```

The **syssurrogateauth** table has the following columns.

**Table 62. SYSSURROGATEAUTH table column descriptions**

| Column               | Type     | Explanation                |
|----------------------|----------|----------------------------|
| <b>trusteduser</b>   | CHAR(32) | Trusted user name or role. |
| <b>surrogateuser</b> | CHAR(32) | Surrogate user name.       |

## SYSSYNONYMS

The **syssynonyms** system catalog table is unused. The **syssynonym** table describes synonyms. The **syssynonyms** system catalog table has the following columns.

**Table 63. SYSSYNONYMS table column descriptions**

| Column         | Type         | Explanation                                    |
|----------------|--------------|--|
| <b>owner</b>   | VARCHAR(32)  | Name of the owner of the synonym               |
| <b>synname</b> | VARCHAR(128) | Name of the synonym                            |
| <b>created</b> | DATE         | Date when the synonym was created              |
| <b>tabid</b>   | INTEGER      | Identifying code of a table, sequence, or view |

## SYSSYNTABLE

The **syssynonym** system catalog table outlines the mapping between each public or private synonym and the database object (table, sequence, or view) that it represents. It contains one row for each entry in the **syntables** table that has a **tabtype** value of `FOR S`. The **syssynonym** table has the following columns.

| Column            | Type         | Explanation   |
|-------------------|--------------|---|
| <b>tabid</b>      | INTEGER      | Identifying code of the public synonym              |
| <b>servername</b> | VARCHAR(128) | Name of an external database server                 |
| <b>dbname</b>     | VARCHAR(128) | Name of an external database                        |
| <b>owner</b>      | VARCHAR(32)  | Name of the owner of an external object             |
| <b>tablename</b>  | VARCHAR(128) | Name of an external table or view                   |
| <b>btabid</b>     | INTEGER      | Identifying code of a base table, sequence, or view |

ANSI-compliant databases do not support public synonyms; their **sysstbtable** tables can describe only synonyms whose **sysstbtable.tabtype** value is `P`.

If you define a synonym for an object that is in your current database, only the **tabid** and **btabid** columns are used. If you define a synonym for a table that is external to your current database, the **btabid** column is not used, but the **tabid**, **servername**, **dbname**, **owner**, and **tablename** columns are used.

The **tabid** column maps to **systables.tabid**. With the **tabid** information, you can determine additional facts about the synonym from **systables**.

An index on the **tabid** column allows only unique values. The **btabid** column is indexed to allow duplicate values.

## SYSTABAMDATA

The **sysstabamdata** system catalog table stores the table-specific hashing parameters of tables that were created with a primary access method.

The **sysstabamdata** table has the following columns.

**Table 64. SYSTABAMDATA table column descriptions**

| Column          | Type           | Explanation                                       |
|-----------------|----------------|---|
| <b>tabid</b>    | INTEGER        | Identifying code of the table                     |
| <b>am_param</b> | LVARCHAR(8192) | Access method parameter choices                   |
| <b>m</b>        | )              |   |
| <b>am_space</b> | VARCHAR(128)   | Name of the storage space holding the data values |

The **am\_param** column stores configuration parameters that determine how a primary access method accesses a given table. Each configuration parameter in the **am\_param** list has the format *keyword=value* or *keyword*.

The **am\_space** column specifies the location of the table. It might be located in a cooked file, a different database, or an sbospace within the database server.

The **tabid** column is the primary key to the **systables** table. This column is indexed and must contain unique values.

## SYSTABAUTH

The **systabauth** system catalog table describes each set of privileges that are granted on a table, view, sequence, or synonym. It contains one row for each set of table privileges that are granted in the database; the REVOKE statement can modify a row. The **systabauth** table has the following columns.

**Table 65. SYSTABAUTH table column descriptions**

| Column         | Type            | Explanation  |
|----------------|-----------------|--|
| <b>grantor</b> | VARCHAR(32)     | Name of the grantor of privilege   |
| <b>grantee</b> | VARCHAR(32)     | Name of the grantee of privilege   |
| <b>tabid</b>   | INTEGER         | Value from <b>systables.tabid</b> for database object  |
| <b>tabauth</b> | CHAR(9) CHAR(8) | Pattern that specifies privileges on the table, view, synonym, or sequence:<br><br>s or S = Select<br>u or U = Update<br>* = Column-level privilege<br>i or I = Insert<br>d or D = Delete<br>x or X = Index<br>a or A = Alter<br>r or R = References<br>n or N = Under privilege |

If the **tabauth** column shows a privilege code in uppercase (for example, **S** for Select), this indicates that the user also has the option to grant that privilege to others. Privilege codes listed in lowercase (for example, **s** for select) indicate that the user has the specified privilege, but cannot grant it to others.

A hyphen ( - ) indicates the absence of the privilege corresponding to that position within the **tabauth** pattern.

A **tabauth** value with an asterisk ( \* ) means column-level privileges exist; see also **syscolauth** (page [SYSINDEXES on page 1586](#)). (In DB-Access, the **Privileges** option of the **Info** command for a specified table can display the column-level privileges on that table.)

A composite index on **tabid**, **grantor**, and **grantee** allows only unique values. A composite index on **tabid** and **grantee** allows duplicate values.

## SYSTABLES

The **systables** system catalog table contains a row for each table object (a table, view, synonym, or in HCL Informix®, a sequence) that has been defined in the database, including the tables and views of the system catalog.

**Table 66. SYSTABLES table column descriptions**

| Column           | Type         | Explanation   |
|------------------|--------------|---|
| <b>tablename</b> | VARCHAR(128) | Name of table, view, synonym, or sequence   |
| <b>owner</b>     | CHAR(32)     | Owner of table (user <b>informix</b> for system catalog tables and <i>username</i> for database tables)   |
| <b>partnum</b>   | INTEGER      | Physical storage location code  |
| <b>tabid</b>     | SERIAL       | System-assigned sequential identifying number   |
| <b>rowsize</b>   | SMALLINT     | Maximum row size in bytes (< 32,768)  |
| <b>ncols</b>     | SMALLINT     | Number of columns in the table  |
| <b>nindexes</b>  | SMALLINT     | Number of indexes on the table  |
| <b>nrows</b>     | FLOAT        | Number of rows in the table   |
| <b>created</b>   | DATE         | Date when table was created or last modified  |
| <b>version</b>   | INTEGER      | Number that changes when table is altered   |
| <b>tabtype</b>   | CHAR(1)      | Code indicating the type of table object: <ul style="list-style-type: none"> <li>• T = Table</li> <li>• E = External Table</li> <li>• V = View</li> <li>• Q = Sequence</li> <li>• P = Private synonym</li> <li>• S = Public synonym</li> </ul> (Type S is unavailable in an ANSI-compliant database.) |
| <b>locklevel</b> | CHAR(1)      | Lock mode for the table: <ul style="list-style-type: none"> <li>• B = Page and row level</li> <li>• P = Page level</li> <li>• R = Row level</li> </ul>  |

Table 66. SYSTABLES table column descriptions (continued)

| Column          | Type         | Explanation  |
|-----------------|--------------|--|
| <b>npused</b>   | FLOAT        | Number of data pages that have ever been initialized in the tablespace by the database server  |
| <b>fextsize</b> | INTEGER      | Size of initial extent (in KB)   |
| <b>nextsize</b> | INTEGER      | Size of all subsequent extents (in KB)   |
| <b>flags</b>    | SMALLINT     | Codes for classifying permanent tables:<br><br><b>ROWID</b><br>1 - Has rowid column defined<br><br><b>UNDER</b><br>2 - Table created under a supertable<br><br><b>VIEWREMOTE</b><br>4 - View is based on a remote table<br><br><b>CDR</b><br>8 - Has CDRCOLS defined<br><br><b>RAW</b><br>16 - (Informix®) RAW table<br><br><b>EXTERNAL</b><br>32 - External table<br><br><b>AUDIT</b><br>64 - Audit table attribute - FGA<br><br><b>AQT</b><br>128 - View is an AQT for DWA offloading<br><br><b>VIRTAQT</b><br>256 - View is a virtual AQT |
| <b>site</b>     | VARCHAR(128) | Reserved for future use  |
| <b>dbname</b>   | VARCHAR(128) | Reserved for future use  |
| <b>type_xid</b> | INTEGER      | Code from <b>sysxdtypes.extended_id</b> for typed tables, or 0 for untyped tables  |
| <b>am_id</b>    | INTEGER      | Access method code (key to <b>sysams</b> table)<br><br>NULL or 0 indicates built-in storage manager  |

**Table 66. SYSTABLES table column descriptions (continued)**

| Column                 | Type                          | Explanation   |
|------------------------|-------------------------------|---|
| <b>pagesize</b>        | INTEGER                       | The pagesize, in bytes, of the dbspace (or dbspaces, if the table is fragmented) where the table data resides.  |
| <b>ustlowts</b>        | DATETIME YEAR TO FRACTION (5) | When table, row, and page-count statistics were last recorded   |
| <b>secpolicyid</b>     | INTEGER                       | ID of the SECURITY policy attached to the table. NULL for non-protected tables  |
| <b>protgranularity</b> | CHAR(1)                       | LBAC granularity level: <ul style="list-style-type: none"> <li>• R: Row level granularity</li> <li>• C: Column level granularity</li> <li>• B: Both column and row granularity</li> <li>• Blank for non-protected tables</li> </ul> |
| <b>statlevel</b>       | CHAR(1)                       | Statistics level <ul style="list-style-type: none"> <li>• T = table</li> <li>• F = fragment</li> <li>• A = automatic</li> </ul>   |
| <b>statchange</b>      | SMALLINT                      | For internal use only   |

Each table, view, sequence, and synonym recorded in the **systables** table is assigned a **tabid**, which is a system-assigned SERIAL value that uniquely identifies the object. The first 99 **tabid** values are reserved for the system catalog. The **tabid** of the first user-defined table object in a database is always 100.

The **tabid** column is indexed and contains only unique values. A composite index on the **tablename** and **owner** columns also requires unique values.

The version column contains an encoded number that is stored in **systables** when a new table is created. Portions of this value are incremented when data-definition statements, such as ALTER INDEX, ALTER TABLE, DROP INDEX, and CREATE INDEX, are performed on the table.

In the **flags** column, ST\_RAW represents a nonlogging permanent table in a database that supports transaction logging.

The setting of the SQL\_LOGICAL\_CHAR parameter is encoded into the **systables.flags** column value in the row that describes the ' **VERSION**' table. Note the leading blank space in the identifier of this system-generated table.

To determine whether the database enables the SQL\_LOGICAL\_CHAR configuration parameter, which can apply logical character semantics to the declarations of character columns, you can execute the following query:

```
SELECT flags INTO $value FROM 'informix'.systables WHERE tablename = ' VERSION';
```

Because the SQL\_LOGICAL\_CHAR setting is encoded in the two least significant bits of the " **VERSION.flags**" value, you can calculate its setting from the returned **flags** value by the following formula:

```
SQL_LOGICAL_CHAR = (value & 0x03) + 1
```

Here **&** is the bitwise **AND** operator. Any SQL\_LOGICAL\_CHAR setting greater than 1 indicates that SQL\_LOGICAL\_CHAR was enabled when the database was created, and that explicit or default maximum size specifications of character columns are multiplied by that setting.

When a prepared statement that references a database table is executed, the version value is checked to make sure that nothing has changed since the statement was prepared. If the version value has been changed by DDL operations that modified the table schema while automatic recompilation was disabled by the IFX\_AUTO\_REPREPARE setting of the SET ENVIRONMENT statement, the prepared statement is not executed, and you must prepare the statement again.

The **npused** column does not reflect the number of pages used for BYTE or TEXT data, nor the number of pages that are freed in DELETE or TRUNCATE operations.

The **nrows** column and the **npused** columns might not accurately reflect the number of rows and the number of data pages used by an external table unless the NUMROWS clause was specified when the external table was created. See the *Informix® Administrator's Guide* for more information.

The **systables** table has two rows that store information about the database locale: GL\_COLLATE with a **tabid** of 90 and GL\_CTYPE with a **tabid** of 91. To view these rows, enter the following SELECT statement:

```
SELECT * FROM systables WHERE tabid=90 OR tabid=91;
```

## SYSTRACECLASSES

The **systraceclasses** system catalog table contains the names and identifiers of trace classes. The **systraceclasses** table has the following columns.

**Table 67. SYSTRACECLASSES table column descriptions**

| Column         | Type     | Explanation                         |
|----------------|----------|-------------------------------------|
| <b>name</b>    | CHAR(18) | Name of the class of trace messages |
| <b>classid</b> | SERIAL   | Identifying code of the trace class |

A *trace class* is a category of trace messages that you can use in the development and testing of new DataBlade® modules and user-defined routines. Developers use the tracing facility by calling the appropriate DataBlade® API routines within their code.

To create a new trace class, insert a row directly into the **systraceclasses** table. By default, all users can view this table, but only users with the DBA privilege can modify it.

The database cannot support tracing unless the MITRACE\_OFF configuration parameter is undefined.

A unique index on the **name** column requires each trace class to have a unique name. The database server assigns to each class a unique sequential code. The index on this **classid** column also allows only unique values.

## SYSTRACEMSGS

The **systracemsgs** system catalog table stores internationalized trace messages that you can use in debugging user-defined routines.

The **systracemsgs** table has the following columns.

**Table 68. SYSTRACEMSGS table column descriptions**

| Column         | Type         | Explanation   |
|----------------|--------------|---|
| <b>name</b>    | VARCHAR(128) | Name of the message   |
| <b>msgid</b>   | SERIAL       | Identifying code of the message template  |
| <b>locale</b>  | CHAR(36)     | Locale with which this version of the message is associated (for example, <b>en_us.8859-1</b> ) |
| <b>seqno</b>   | SMALLINT     | Reserved for future use   |
| <b>message</b> | VARCHAR(255) | The message text  |

DataBlade® module developers create a trace message by inserting a row directly into the **systracemsgs** table. After a message is created, the development team can specify it either by name or by **msgid** code, using trace statements that the DataBlade® API provides.

To create a trace message, you must specify its name, locale, and text. By default, all users can view the **systracemsgs** table, but only users with the DBA privilege can modify it.

The database cannot support tracing unless the MITRACE\_OFF configuration parameter is undefined.

A unique composite index is defined on the **name** and **locale** columns. Another unique index is defined on the **msgid** column.

## SYSTRIGBODY

The **systrigbody** system catalog table contains the ASCII text of the trigger definition and the linearized code for the trigger. *Linearized code* is binary data and code that is represented in ASCII format.

**Important:** The database server uses the linearized code that is stored in **systrigbody**. You must not alter the content of rows that contain linearized code.

The **systrigbody** table has the following columns.

**Table 69. SYSTRIGBODY table column descriptions**

| Column         | Type      | Explanation  |
|----------------|-----------|--|
| <b>trigid</b>  | INTEGER   | Identifying code of the trigger  |
| <b>datakey</b> | CHAR(1)   | Code specifying the type of data:<br><br>A = ASCII text for the body, triggered actions<br>B = Linearized code for the body<br>D = English text for the header, trigger definition<br>H = Linearized code for the header<br>S = Linearized code for the symbol table |
| <b>seqno</b>   | INTEGER   | Page number of this data segment   |
| <b>data</b>    | CHAR(256) | English text or linearized code  |

A composite index on the **trigid**, **datakey**, and **seqno** columns allows only unique values.

## SYSTRIGGERS

The **systriggers** system catalog table contains information about the SQL triggers in the database. This information includes the triggering event and the correlated reference specification for the trigger. The **systriggers** table has the following columns.

**Table 70. SYSTRIGGERS table column descriptions**

| Column          | Type         | Explanation   |
|-----------------|--------------|---|
| <b>trigid</b>   | SERIAL       | Identifying code of the trigger   |
| <b>trigname</b> | VARCHAR(128) | Name of the trigger   |
| <b>owner</b>    | VARCHAR(32)  | Name of the owner of the trigger  |
| <b>tabid</b>    | INTEGER      | Identifying code of the triggering table  |
| <b>event</b>    | CHAR(1)      | Code for the type of triggering event:<br><br>D = Delete trigger<br>I = Insert trigger<br>U = Update trigger<br>S = Select trigger<br>d = INSTEAD OF Delete trigger<br>i = INSTEAD OF Insert trigger<br>u = INSTEAD OF Update trigger |

**Table 70. SYSTRIGGERS table column descriptions (continued)**

| Column           | Type         | Explanation  |
|------------------|--------------|--|
| <b>old</b>       | VARCHAR(128) | Name of value before update                              |
| <b>new</b>       | VARCHAR(128) | Name of value after update                               |
| <b>mode</b>      | CHAR(1)      | Reserved for future use                                  |
| <b>collation</b> | CHAR(32)     | Collating order at the time when the routine was created |

A composite index on the **trigname** and **owner** columns allows only unique values. An index on the **trigid** column also requires unique values. An index on the **tabid** column allows duplicate values.

## SYSUSERS

The **sysusers** system catalog table lists the authorization identifier of every individual user, or public for the PUBLIC group, who holds database-level access privileges. This table also lists the name of every role that holds access privileges on any object in the database.

This system catalog table has the following columns:

**Table 71. SYSUSERS table column descriptions**

| Column           | Type        | Explanation   |
|------------------|-------------|---|
| <b>user</b>      | VARCHAR(32) | Name of the database user or role.  |
| <b>name</b>      | CHAR(32)    | An index on <b>username</b> allows only unique values. The <b>username</b> value can be the login name of a user or the name of a role.   |
| <b>user type</b> | CHAR(1)     | Code specifying the highest database-level privilege held by <b>username</b> , where <b>username</b> is an individual user or the PUBLIC group, or a role name. The valid codes are: <ul style="list-style-type: none"> <li>D = DBA (all privileges)</li> <li>R = Resource (create UDRs, UDTs, permanent tables, and indexes)</li> <li>C = Connect (work with existing tables)</li> <li>G = Role</li> <li>U = Default role. When a user is assigned a default role, an implicit connection to the database is granted to the user. This is the role the user has before being granted a C, D, or R role.</li> </ul> |
| <b>prior</b>     | SMALLINT    | Reserved for future use.  |
| <b>id</b>        | INT         |   |

**Table 71. SYSUSERS table column descriptions**

(continued)

| Column              | Type        | Explanation               |
|---------------------|-------------|---------------------------|
| <b>passwd</b>       | CHAR(16)    | Reserved for future use.  |
| <b>default_role</b> | VARCHAR(32) | Name of the default role. |

## SYSVIEWS

The **sysviews** system catalog table describes each view in the database. Because it stores the SELECT statement that created the view, **sysviews** can contain multiple rows for each view. It has the following columns.

| Column          | Type      | Explanation                                     |
|-----------------|-----------|---|
| <b>tabid</b>    | INTEGER   | Identifying code of the view                    |
| <b>seqno</b>    | SMALLINT  | Line number of the SELECT statement             |
| <b>viewtext</b> | CHAR(256) | Actual SELECT statement used to create the view |

A composite index on **tabid** and **seqno** allows only unique values.

## SYSVIOLATIONS

The **sysviolations** system catalog table stores information about constraint violations for base tables.

This table is updated when the DELETE, INSERT, MERGE, or UPDATE statement detects a violation of an enabled constraint or unique index in a database table for which the START VIOLATIONS TABLE statement of SQL has created an associated violations table (and for Informix®, a diagnostics table). For each base table that has an active violations table, the **sysviolations** table has a corresponding row, with the following columns.

| Column           | Type    | Explanation   |
|------------------|---------|---|
| <b>targettid</b> | INTEGER | Identifying code of the <i>target table</i> (the base table on which the violations table and the diagnostic table are defined) |
| <b>viotid</b>    | INTEGER | Identifying code of the violations table  |

| Column         | Type    | Explanation  |
|----------------|---------|--|
| <b>diatid</b>  | INTEGER | Identifying code of the diagnostics table  |
| <b>maxrows</b> | INTEGER | Maximum number of rows that can be inserted into the diagnostics table by a single insert, update, or delete operation on a target table that has a filtering mode object defined on it. |

The **maxrows** column also signifies the maximum number of rows that can be inserted in the diagnostics table during a single operation that enables a disabled object or that sets a disabled object to filtering mode (provided that a diagnostics table exists for the target table). If no maximum is specified for the diagnostics or violations table, then **maxrows** contains a NULL value.

The primary key of this table is the **targettid** column. An additional unique index is also defined on the **viotid** column.

HCL Informix® also has a unique index on the **diatid** column.

## SYSXADATASOURCES

The **sysxdatasources** system catalog table stores XA data sources.

The **sysxdatasources** table has the following columns.

| Column                  | Type         | Explanation                             |
|-------------------------|--------------|---|
| <b>xa_datasrc_owner</b> | CHAR(32)     | The user ID of the XA data source owner |
| <b>xa_datasrc_name</b>  | VARCHAR(128) | The name of the XA data source          |
| <b>xa_datasrc_rmid</b>  | SERIAL       | Unique RMID of the XA data source       |
| <b>xa_source_typeid</b> | INTEGER      | XA data source type ID                  |

## SYSXASOURCETYPES

The **sysxasourcetypes** system catalog table stores XA data source types.

The **sysxasourcetypes** table has the following columns.

| Column                  | Type         | Explanation                             |
|-------------------------|--------------|---|
| <b>xa_source_typeid</b> | SERIAL       | A unique identifier for the source type |
| <b>xa_source_owner</b>  | CHAR(32)     | The user ID of the owner                |
| <b>xa_source_name</b>   | VARCHAR(128) | The name of the source type             |
| <b>xa_flags</b>         | INTEGER      |   |

| Column             | Type    | Explanation                 |
|--------------------|---------|-----------------------------|
| <b>xa_version</b>  | INTEGER |                             |
| <b>xa_open</b>     | INTEGER | UDR ID of xa_open_entry     |
| <b>xa_close</b>    | INTEGER | UDR ID of xa_close_entry    |
| <b>xa_start</b>    | INTEGER | UDR ID of xa_start entry    |
| <b>xa_end</b>      | INTEGER | UDR ID of xa_end_entry      |
| <b>xa_rollback</b> | INTEGER | UDR ID of xa_rollback_entry |
| <b>xa_prepare</b>  | INTEGER | UDR ID of xa_prepare_entry  |
| <b>xa_commit</b>   | INTEGER | UDR ID of xa_commit_entry   |
| <b>xa_recover</b>  | INTEGER | UDR ID of xa_recover_entry  |
| <b>xa_forget</b>   | INTEGER | UDR ID of xa_forget_entry   |
| <b>xa_complete</b> | INTEGER | UDR ID of xa_complete_entry |

## SYSXTDESC

The **sysxtddesc** system catalog table provides a text description of each user-defined data type (UDT) defined in the database. The **sysxtddesc** table has the following columns.

| Column             | Type      | Explanation   |
|--------------------|-----------|---|
| <b>extended_id</b> | INTEGER   | Code uniquely identifying the extended data types   |
| <b>seqno</b>       | SMALLINT  | Value to order and identify one line of the description of the UDT<br>A new line is created only if the remaining text string is larger than 255 bytes. |
| <b>description</b> | CHAR(256) | Textual description of the extended data type   |

A composite index on **extended\_id** and **seqno** allows duplicate values.

## SYSXTDTYPEAUTH

The **sysxtdtypeauth** system catalog table identifies the privileges on each UDT (user-defined data type).

The **sysxtdtypeauth** table contains one row for each set of privileges granted and has the following columns:

| Column         | Type        | Explanation   |
|----------------|-------------|---|
| <b>grantor</b> | VARCHAR(32) | Name of grantor of privilege  |
| <b>grantee</b> | VARCHAR(32) | Name of grantee of privilege  |
| <b>type</b>    | INTEGER     | Code identifying the UDT  |
| <b>auth</b>    | CHAR(2)     | Code identifying privileges on the UDT:<br><br>n or N = Under privilege<br>u or U = Usage privilege |

If the privilege code in the **auth** column is upper case (for example, 'U' for usage), a user who has this privilege can also grant it to others. If the code is in lower case, a user who has the privilege cannot grant it to others.

A composite index on **type**, **grantor**, and **grantee** allows only unique values. A composite index on the **type** and **grantee** columns allows duplicate values.

## SYSXTDTYPES

The **sysxtdtypes** system catalog table has an entry for each UDT (user-defined data type), including opaque and distinct data types and complex data types (named ROW types, unnamed ROW types, and COLLECTION types), that is defined in the database.

The **sysxtdtypes** table has the following columns.

**Table 72. SYSXTDTYPES table column descriptions**

| Column             | Type        | Explanation   |
|--------------------|-------------|---|
| <b>extended_id</b> | SERIAL      | Unique identifying code for extended data type  |
| <b>domain</b>      | CHAR(1)     | Code for the domain of the UDT  |
| <b>mode</b>        | CHAR(1)     | Code classifying the UDT: <ul style="list-style-type: none"> <li>• B = Base (opaque) type</li> <li>• C = Collection type or unnamed ROW type</li> <li>• D = Distinct type</li> <li>• R = Named ROW type</li> <li>• S = Reserved for internal use</li> <li>• T = Reserved for internal use</li> <li>• ' ' (blank) = Built-in type</li> </ul> |
| <b>owner</b>       | VARCHAR(32) | Name of the owner of the UDT  |

**Table 72. SYSXTDTYPES table column descriptions**

(continued)

| Column           | Type          | Explanation   |
|------------------|---------------|---|
| <b>name</b>      | VARCHAR(128 ) | Name of the UDT   |
| <b>type</b>      | SMALLINT      | Code classifying the UDT  |
| <b>source</b>    | INTEGER       | The <b>sysxtdtypes</b> reference (for distinct types only)<br>Zero (0) indicates that a distinct UDT was created from a built-in data type. |
| <b>maxlen</b>    | INTEGER       | The maximum length for variable-length data types<br>Zero indicates a fixed-length UDT.   |
| <b>length</b>    | INTEGER       | The length in bytes for fixed-length data types<br>Zero indicates a variable-length UDT.  |
| <b>byvalue</b>   | CHAR(1)       | 'T' = UDT is passed by value<br>'F' = UDT is not passed by value  |
| <b>canonhash</b> | CHAR(1)       | 'T' = UDT is hashable by default hash function<br>'F' = UDT is not hashable by default function   |
| <b>align</b>     | SMALLINT      | Alignment ( = 1, 2, 4, or 8) for this UDT   |
| <b>locator</b>   | INTEGER       | Locator key for unnamed ROW type  |

Each extended data type is characterized by a unique identifier, called an extended identifier (**extended\_id**), a data type identifier (**type**), and the length and description of the data type.

For distinct types created from built-in data types, the **type** column codes correspond to the value of the **syscolumns.coltype** column (indicating the source type) as listed on page [SYSCOLUMNS on page 1568](#), but incremented by the hexadecimal value 0x0000800. The file `$INFORMIXDIR/incl/esql/sqltypes.h` contains information about **sysxtdtypes.type** and **syscolumns.coltype** codes.

An index on the **extended\_id** column allows only unique values. An index on the **locator** column allows duplicate values, as does a composite index on the **name** and **owner** columns. A composite index on the **type** and **source** columns also allows duplicate values.

## Information Schema

The Information Schema consists of read-only views that provide information about all the tables, views, and columns in the current database server to which you have access. These views also provide information about SQL dialects (such as HCL

Informix®, Oracle, or Sybase) and SQL standards. Note that unlike a system catalog, whose tables describes an individual database, these views describe the HCL Informix® instance, rather than a single database.

This version of the Information Schema views is an X/Open CAE standard. These standards are provided so that applications developed on other database systems can obtain HCL Informix® system catalog information without accessing the HCL Informix® system catalog tables directly.

**Important:** Because the X/Open CAE standard for Information Schema views differs from ANSI-compliant Information Schema views, it is recommended that you do not install the X/Open CAE Information Schema views on ANSI-compliant databases.

The following Information Schema views are available:

- **tables**
- **columns**
- **sql\_languages**
- **server\_info**

Sections that follow contain information about how to generate and access Information Schema views and information about their structure.

## Generating the Information Schema Views

### About this task

The Information Schema views are generated automatically when you, as DBA, run the following DB-Access command:

```
dbaccess database-name $INFORMIXDIR/etc/xpg4_is.sql
```

The views display data from the system catalog tables. If tables, views, or routines exist with any of the same names as the Information Schema views, you must either rename those database objects or rename the views in the script before you can install the views. You can drop the views with the DROP VIEW statement on each view. To re-create the views, rerun the script.

**Important:** In addition to the columns specified for each Information Schema view, individual vendors might include additional columns or change the order of the columns. It is recommended that applications not use the forms SELECT \* or SELECT table-name\* to access an Information Schema view.

## Accessing the Information Schema Views

All Information Schema views have the Select privilege granted to PUBLIC WITH GRANT OPTION so that all users can query the views. Because no other privileges are granted on the Information Schema views, they cannot be updated.

You can query the Information Schema views as you would query any other table or view in the database.

## Structure of the Information Schema Views

The following Information Schema views are described in this section:

- **tables**
- **columns**
- **sql\_languages**
- **server\_info**

In order to accept long identifier names, most of the columns in the views are defined as VARCHAR data types with large maximum sizes.

### The tables Information Schema View

The **tables** Information Schema view contains one row for each table to which you have access. It contains the following columns.

| Column              | Data Type    | Explanation                           |
|---------------------|--------------|---------------------------------------|
| <b>table_schema</b> | VARCHAR(32)  | Name of owner of table                |
| <b>table_name</b>   | VARCHAR(128) | Name of table or view                 |
| <b>table_type</b>   | VARCHAR(128) | BASE TABLE for table or VIEW for view |
| <b>remarks</b>      | VARCHAR(255) | Reserved for future use               |

The visible rows in the **tables** view depend on your privileges. For example, if you have one or more privileges on a table (such as Insert, Delete, Select, References, Alter, Index, or Update on one or more columns), or if privileges are granted to PUBLIC, you see the row that describes that table.

### The columns Information Schema View

The **columns** Information Schema view contains one row for each accessible column. It contains the following columns.

**Table 73. Description of the columns Information Schema View**

| Column                    | Data Type    | Explanation  |
|---------------------------|--------------|--|
| <b>table_schema</b>       | VARCHAR(128) | Name of owner of table   |
| <b>table_name</b>         | VARCHAR(128) | Name of table or view  |
| <b>column_name</b>        | VARCHAR(128) | Name of the column in the table or view  |
| <b>ordinal_position</b>   | INTEGER      | Position of the column within its table<br><br>The <b>ordinal_position</b> value is a sequential number that starts at 1 for the first column. This is the HCL Informix® extension to XPG4.  |
| <b>data_type</b>          | VARCHAR(254) | Name of the data type of the column, such as CHARACTER or DECIMAL  |
| <b>char_max_length</b>    | INTEGER      | Maximum length (in bytes) for character data types; NULL otherwise   |
| <b>numeric_precision</b>  | INTEGER      | Uses one of the following values: <ul style="list-style-type: none"> <li>• Total number of digits for exact numeric data types (DECIMAL, INTEGER, MONEY, SMALLINT)</li> <li>• Number of digits of mantissa precision (machine-dependent) for approximate data types (FLOAT, SMALLFLOAT)</li> <li>• NULL for all other data types.</li> </ul> |
| <b>numeric_prec_radix</b> | INTEGER      | Uses one of the following values: <ul style="list-style-type: none"> <li>• 2 = Approximate data types (FLOAT and SMALLFLOAT)</li> <li>• 10 = Exact numeric data types (DECIMAL, INTEGER, MONEY, and SMALLINT)</li> <li>• NULL for all other data types</li> </ul>  |
| <b>numeric_scale</b>      | INTEGER      | Number of significant digits to the right of the decimal point for DECIMAL and MONEY data types<br><br>0 for INTEGER and SMALLINT types NULL for all other data types  |
| <b>datetime_precision</b> | INTEGER      | Number of digits in the fractional part of the seconds for DATE and DATETIME columns; NULL otherwise<br><br>This column is the HCL Informix® extension to XPG4.  |

**Table 73. Description of the columns Information Schema View (continued)**

| Column             | Data Type    | Explanation   |
|--------------------|--------------|---|
| <b>is_nullable</b> | VARCHAR(3)   | Indicates whether a column allows NULL values; either YES or NO |
| <b>remarks</b>     | VARCHAR(254) | Reserved for future use   |

## The sql\_languages Information Schema View

The **sql\_languages** Information Schema view contains a row for each instance of conformance to standards that the current database server supports. The **sql\_languages** view contains the following columns.

| Column                  | Data Type    | Explanation  |
|-------------------------|--------------|--|
| <b>source</b>           | VARCHAR(254) | Organization defining this SQL version   |
| <b>source_year</b>      | VARCHAR(254) | Year the source document was approved  |
| <b>conformance</b>      | VARCHAR(254) | Standard to which the server conforms  |
| <b>integrity</b>        | VARCHAR(254) | Indication of whether this is an integrity enhancement feature; either YES or NO |
| <b>implementation</b>   | VARCHAR(254) | Identification of the SQL product of the vendor                                  |
| <b>binding_style</b>    | VARCHAR(254) | Direct, module, or other binding style   |
| <b>programming_lang</b> | VARCHAR(254) | Host language for which binding style is adapted                                 |

The **sql\_languages** view is completely visible to all users.

## The server\_info Information Schema View

The **server\_info** Information Schema view describes the database server to which the application is currently connected. It contains two columns.

| Column                  | Data Type    | Explanation   |
|-------------------------|--------------|---|
| <b>server_attribute</b> | VARCHAR(254) | An attribute of the database server   |
| <b>attribute_value</b>  | VARCHAR(254) | Value of the <b>server_attribute</b> as it applies to the current database server |

Each row in this view provides information about one attribute. X/Open-compliant databases must provide applications with certain required information about the database server.

The **server\_info** view includes the following **server\_attribute** information.

| server_attribute         | Explanation   |
|--------------------------|---|
| <b>identifier_length</b> | Maximum number of bytes for a user-defined identifier   |
| <b>row_length</b>        | Maximum number of bytes in a row  |
| <b>userid_length</b>     | Maximum number of bytes in a user name  |
| <b>txn_isolation</b>     | Initial transaction isolation level for the database server:<br><br>Read Uncommitted (= Default isolation level for databases with no transaction logging; also called Dirty Read)<br><br>Read Committed (= Default isolation level for databases that are not ANSI-compliant, but that support explicit transaction logging)<br><br>Serializable (= Default isolation level for ANSI-compliant databases; also called Repeatable Read) |
| <b>collation_seq</b>     | Assumed ordering of the character set for the database server The following values are possible: ISO 8859-1 EBCDIC<br><br>The default HCL Informix® representation shows ISO 8859-1.  |

The **server\_info** view is completely visible to all users.

## Data types

Every column in a table in a database is assigned a data type. The data type precisely defines the kinds of values that you can store in that column.

These topics describe built-in and extended data types, casting between two data types, and operator precedence.

## Summary of data types

HCL Informix® supports the most common set of built-in data types. Additionally, an extended set of data types are supported on the database server.

You can use both *built-in* data types (which are system-defined) and *extended* data types (which you can define) in the following ways:

- Use them to create columns within database tables.
- Declare them as arguments and as returned types of routines.
- Use them as base types from which to create DISTINCT data types.
- Cast them to other data types.
- Declare and access host variables of these types in SPL and ESQL/C.

You assign data types to columns with the CREATE TABLE statement and change them with the ALTER TABLE statement. When you change an existing column data type, all data is converted to the new data type, if possible.

For information about the ALTER TABLE and CREATE TABLE statements, on SQL statements that create specific data types, that create and drop casts, and on other data type topics, see the *Informix® Guide to SQL: Syntax*.

For information about how to create and use complex data types supported by HCL Informix®, see the *Informix® Database Design and Implementation Guide*. For information about how to create user-defined data types, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

Some data types can be used in distributed SQL operations, while others can be used only in SQL operations within the same database.

### **Built-in data types supported in local and distributed SQL operations**

The following table lists all of the built-in SQL data types that Informix® supports. These built-in SQL data types are valid in all Informix® SQL transactions, including data-manipulation language (DML) operations of these types:

- Operations on objects in the local database
- Cross-database operations on objects in databases of the local server instance
- Cross-server operations on objects in databases of two or more database server instances

**Table 74. Data types supported in all operations**

| Data type  | Explanation   |
|--|---|
| <a href="#">BIGINT data type on page 1631</a>                    | Stores 8-byte integer values from $-(2^{63} - 1)$ to $2^{63} - 1$   |
| <a href="#">BIGSERIAL data type on page 1631</a>                 | Stores sequential, 8-byte integers from 1 to $2^{63} - 1$   |
| <a href="#">BSON and JSON built-in opaque data types on page</a> | The BSON data type is the binary representation of a JSON data type format for serializing JSON documents. The JSON data type is a plain text format for entering and displaying structured data. |
| <a href="#">BYTE data type on page 1633</a>                      | Stores any kind of binary data, up to $2^{31}$ bytes in length  |
|  | Stores character strings; collation is in code-set order  |
| <a href="#">CHARACTER(n) data type on page 1634</a>              | Is a synonym for CHAR   |
| <a href="#">CHARACTER VARYING(m,r) data type on page 1634</a>    | Stores character strings of varying length (ANSI-compliant); collation is in code-set order   |
| <a href="#">DATE data type on page 1636</a>                      | Stores calendar dates   |
|  | Stores calendar date combined with time of day  |
| <a href="#">DEC data type on page 1636</a>                       | Is a synonym for DECIMAL  |
| <a href="#">DECIMAL on page 1636</a>                             | Stores floating-point numbers with definable precision; if database is ANSI-compliant, the scale is zero  |
| <a href="#">DECIMAL (p,s) Fixed Point on page 1637</a>           | Stores fixed-point numbers of defined scale and precision   |
| <a href="#">DOUBLE PRECISION data types on page 1639</a>         | Synonym for FLOAT   |
| <a href="#">FLOAT(n) on page 1639</a>                            | Stores double-precision floating-point numbers corresponding to the <b>double</b> data type in C  |
| <a href="#">INT data type on page 1640</a>                       | Is a synonym for INTEGER  |
| <a href="#">INT8 on page 1640</a>                                | Stores 8-byte integer values from $-(2^{63} - 1)$ to $2^{63} - 1$   |
| <a href="#">INTEGER data type on page 1641</a>                   | Stores whole numbers from -2,147,483,647 to +2,147,483,647  |
|  | Stores a span of time (or level of effort) in units of <i>years</i> and <i>months</i> .   |
|  | Stores a span of time in a contiguous set of units of <i>days</i> , <i>hours</i> , <i>minutes</i> , <i>seconds</i> , and <i>fractions of a second</i>   |
| <a href="#">MONEY(p,s) data type on page 1643</a>                | Stores currency amounts   |

**Table 74. Data types supported in all operations (continued)**

| Data type  | Explanation  |
|--|--|
| <a href="#">NCHAR(n) data type on page 1645</a>      | Same as CHAR, but can support localized collation  |
| <a href="#">NUMERIC(p,s) data type on page 1645</a>  | Synonym for DECIMAL(p,s)   |
| <a href="#">NVARCHAR(m,r) data type on page 1645</a> | Same as VARCHAR, but can support localized collation   |
| <a href="#">REAL data type on page 1646</a>          | Is a synonym for SMALLFLOAT  |
| <a href="#">SERIAL(n) data type on page 1649</a>     | Stores sequential integers (> 0) in positive range of INT  |
| <a href="#">SERIAL8(n) data type on page 1650</a>    | Stores sequential integers (> 0) in positive range of INT8   |
| <a href="#">SMALLFLOAT on page 1652</a>              | Stores single-precision floating-point numbers corresponding to the <b>float</b> data type of the C language |
| <a href="#">SMALLINT data type on page 1653</a>      | Stores whole numbers from -32,767 to +32,767   |
| <a href="#">TEXT data type on page 1653</a>          | Stores any kind of text data, up to 2 <sup>31</sup> bytes in length  |
| <a href="#">VARCHAR(m,r) data type on page 1655</a>  | Stores character strings of varying length (up to 255 bytes); collation is in code-set order                 |

In cross-server MERGE operations, the source table (but not the target table) can be in a database of a remote Informix® server.

For the character data types (CHAR, CHAR VARYING, LVARCHAR, NCHAR, NVARCHAR, and VARCHAR), a data string can include letters, digits, punctuation, whitespace, diacritical marks, ligatures, and other printable symbols from the code set of the database locale. For **UTF-8** and for code sets of some East Asian locales, multibyte characters are supported within data strings.

### Built-in data types supported only in local database SQL operations

The following table lists the data types that Informix® supports only for use in SQL operations in a local database.

**Table 75. Data types supported in a local database**

| Data type                                   | Explanation                                |
|---|--|
| <a href="#">BLOB data type on page 1632</a> | Stores binary data in random-access chunks |

**Table 75. Data types supported in a local database (continued)**

| Data type   | Explanation   |
|---|---|
| The binary18 data type on page                            | Stores 18 byte binary-encoded strings   |
| The binaryvar data type on page                           | Stores binary-encoded strings with a maximum length of 255 bytes  |
| BOOLEAN data type on page 1633                            | Stores Boolean values true and false  |
| CLOB data type on page 1635                               | Stores text data in random-access chunks  |
| DISTINCT data types on page 1638                          | Stores data in a user-defined type that has the same format as a source type on which it is based, but its casts and functions can differ from those on the source type |
| Calendar data type on page                                | Stores a calendar for a TimeSeries data type  |
| CalendarPattern data type on page                         | Stores the structure of the calendar pattern for a Calendar data type   |
| IDSSECURITYLABEL data type on page 1640                   | Stores LBAC security label objects.   |
| LIST(e) data type on page 1641                            | Stores a sequentially ordered collection of elements, all of the same data type, e; allows duplicate values   |
| The lld_locator data type on page                         | Stores a large object identifier  |
| The lld_lob data type on page                             | Stores the location of a smart large object and specifies whether the object contains binary or character data  |
| LVARCHAR(m) data type on page 1642                        | Stores variable-length strings of up to 32,739 bytes  |
| MULTISET(e) data type on page 1644                        | Stores a non-ordered collection of values, with elements all of the same data type, e; allows duplicate values.   |
| The node data type for querying hierarchical data on page | Stores a combination of integers and decimal points that represents hierarchical relationships, of variable length up to 256 characters                                 |
| OPAQUE data types on page 1646                            | Stores a user-defined data type whose internal structure is inaccessible to the database server   |

**Table 75. Data types supported in a local database (continued)**

| Data type   | Explanation  |
|---|--|
| <a href="#">ROW data type, Named on page 1646</a>   | Stores a named ROW type  |
| <a href="#">ROW data type, Unnamed on page 1648</a> | Stores an unnamed ROW type   |
| <a href="#">SET(e) data type on page 1651</a>       | Stores a non-ordered collection of elements, all of the same data type, e; does not allow duplicate values |
| <a href="#">TimeSeries data type on page</a>        | Stores a collection of row subtypes  |

These extended data types of Informix® are individually described in other topics. These data types are valid in local operations on databases where the data types are defined.

### Extended data types in cross-database distributed SQL transactions

Distributed operations on other databases of the same Informix® instance can access BOOLEAN, BLOB, CLOB, and LVARCHAR data types, which are implemented as built-in opaque types. Such operations can also access DISTINCT types whose base types are built-in types, and user-defined types (UDTs), if the UDTs and DISTINCT types are explicitly cast to built-in types, and if all of the UDTs, casts, and DISTINCT types are defined in all the participating databases.

You cannot, however, reference the following extended data types in cross-database transactions that access multiple databases of the local Informix® instance:

- UDTs that are not cast to built-in data types
- DISTINCT types that are not cast to built-in data types
- Collection data types
- Named or unnamed ROW data types

### Extended data types in cross-server distributed SQL transactions

Distributed SQL transactions and function calls that access databases of other Informix® instances cannot return values of complex or smart large object data types, nor of most distinct or built-in opaque data types. Among the extended data types, only the following can be accessed in cross-server SQL operations:

- Any non-opaque built-in data type
- BOOLEAN
- DISTINCT of non-opaque built-in types
- DISTINCT of BOOLEAN
- DISTINCT of LVARCHAR
- DISTINCT of any of the DISTINCT types listed above
- IDSSECURITYLABEL
- LVARCHAR

A cross-server distributed SQL transaction can support DISTINCT data types only if they are cast explicitly to built-in types, and all of the DISTINCT types, their data type hierarchies, and their casts are defined exactly the same way in each database that participates in the distributed operation. For queries or other DML operations in cross-server UDRs that use the data types in the preceding list as parameters or as returned data types, the UDR must also have the same definition in every participating database.

The built-in DISTINCT data type IDSSecurityLabel, which stores security label objects, can be accessed in cross-server and cross-database operations on protected data by users who hold sufficient security credentials. Like local operations on protected data, distributed queries that access remote tables protected by a security policy can return only the qualifying rows that IDSLBACRules allow, after the database server has compared the security label that secures the data with the security credentials of the user who issues the query.

#### Related information

[Extended Data Types on page 1666](#)

## Description of Data Types

This section describes the data types that HCL Informix® supports.

### BIGINT data type

The BIGINT data type stores integers from  $-(2^{63}-1)$  to  $2^{63}-1$ , which is  $-9,223,372,036,854,775,807$  to  $9,223,372,036,854,775,807$ , in eight bytes.

This data type has storage advantages over INT8 and advantages for some arithmetic operations and sort comparisons over INT8 and DECIMAL data types.

### BIGSERIAL data type

The BIGSERIAL data type stores a sequential integer, of the BIGINT data type, that is assigned automatically by the database server when a new row is inserted. The behavior of the BIGSERIAL data type is similar to the SERIAL data type, but with a larger range.

The default BIGSERIAL starting number is 1, but you can assign an initial value,  $n$ , when you create or alter the table. The value of  $n$  must be a positive integer in the range of 1 to  $9,223,372,036,854,775,807$ . If you insert the value zero (0) in a BIGSERIAL column, the value that is used is the maximum positive value that already exists in the BIGSERIAL column + 1. If you insert any value that is not zero, that value will be inserted as it is.

A table can have no more than one SERIAL column, but it can have a SERIAL column and either a SERIAL8 column or a BIGSERIAL column.

For information about:

- The SERIAL data type, see [SERIAL\(n\) data type on page 1649](#)
- Using the SERIAL8 data type with the INT8 or BIGINT data type, see [Using SERIAL8 and BIGSERIAL with INT8 or BIGINT on page 1632](#)

## Using SERIAL8 and BIGSERIAL with INT8 or BIGINT

All the arithmetic operators that are valid for INT8 and BIGINT (such as +, -, \*, and /) and all the SQL functions that are valid for INT8 and BIGINT (such as ABS, MOD, POW, and so on) are also valid for SERIAL8 and BIGSERIAL values.

Data conversion rules that apply to INT8 and BIGINT also apply to SERIAL8 and BIGSERIAL, but with a NOT NULL constraint on SERIAL8 or BIGSERIAL.

The value of a SERIAL8 or BIGSERIAL column of one table can be stored in INT8 or BIGINT columns of another table. In the second table, however, the INT8 or BIGINT values are not subject to the constraints on the original SERIAL8 or BIGSERIAL column.

## BLOB data type

The BLOB data type stores any kind of binary data in random-access chunks, called sbspaces. Binary data typically consists of saved spreadsheets, program-load modules, digitized voice patterns, and so on. The database server performs no interpretation of the contents of a BLOB column.

A BLOB column can be up to 4 terabytes ( $4 \times 2^{40}$  bytes) in length, though your system resources might impose a lower practical limit. The minimum amount of disk space allocated for smart large object data types is 512 bytes.

The term *smart large object* refers to BLOB and CLOB data types. Use CLOB data types (see page [CLOB data type on page 1635](#)) for random access to text data. For general information about BLOB and CLOB data types, see [Smart large objects on page 1660](#).

You can use these SQL functions to perform operations on a BLOB column:

- **FILETOBLOB** copies a file into a BLOB column.
- **LOTOFILE** copies a BLOB (or CLOB) value into an operating-system file.
- **LOCOPY** copies an existing smart large object to a new smart large object.

For more information about these SQL functions, see the *Informix® Guide to SQL: Syntax*.

Within SQL, you are limited to the equality (=) comparison operation and the encryption and decryption functions for BLOB data. (The encryption and decryption functions are described in the *Informix® Guide to SQL: Syntax*.) To perform additional operations, you must use one of the application programming interfaces (APIs) from within your client application.

You can insert data into BLOB columns in the following ways:

- With the dbload or onload utilities
- With the LOAD statement (DB-Access)
- With the FILETOBLOB function
- From BLOB (**ifx\_lo\_t**) host variables ( Informix® ESQL/C)

If you select a BLOB column using DB-Access, only the string `<SBlob value>` is returned; no actual value is displayed.

## BOOLEAN data type

The BOOLEAN data type stores `TRUE` or `FALSE` data values as a single byte.

The following table shows internal and literal representations of the BOOLEAN data type.

| Logical Value | Internal Representation | Literal Representation |
|---------------|-------------------------|------------------------|
| TRUE          | \0                      | 't'                    |
| FALSE         | \1                      | 'f'                    |
| NULL          | Internal Use Only       | NULL                   |

You can compare two BOOLEAN values to test for equality or inequality. You can also compare a BOOLEAN value to the Boolean literals `'t'` and `'f'`. BOOLEAN values are not case-sensitive; `'t'` is equivalent to `'T'` and `'f'` to `'F'`.

You can use a BOOLEAN column to store what a Boolean expression returns. In the following example, the value of **boolean\_column** is `'t'` if **column1** is less than **column2**, `'f'` if **column1** is greater than or equal to **column2**, and NULL if the value of either **column1** or **column2** is unknown:

```
UPDATE my_table SET boolean_column = lessthan(column1, column2)
```

## BYTE data type

The BYTE data type stores any kind of binary data in an undifferentiated byte stream. Binary data typically consists of digitized information, such as spreadsheets, program load modules, digitized voice patterns, and so on.

The term *simple large object* refers to an instance of a TEXT or BYTE data type. No more than 195 columns of the same table can be declared as BYTE and TEXT data types.

The BYTE data type has no maximum size. A BYTE column has a theoretical limit of  $2^{31}$  bytes and a practical limit that your disk capacity determines.

You cannot use the MEDIUM or HIGH options of the UPDATE STATISTICS statement to calculate distribution statistics on BYTE columns.

## BYTE objects in DML operations

You can store, retrieve, update, or delete the contents of a BYTE column. You cannot, however, use BYTE operands in arithmetic or string operations, nor assign literals to BYTE columns with the SET clause of the UPDATE statement. You also cannot use BYTE objects in any of the following contexts in a SELECT statement:

- With aggregate functions
- With the IN clause
- With the MATCHES or LIKE clauses
- With the GROUP BY clause
- With the ORDER BY clause

BYTE operands are valid in Boolean expressions only when you are testing for NULL values with the IS NULL or IS NOT NULL operators.

You can use the following methods, which can load rows or update fields, to insert BYTE data:

- With the **dbload** or **onload** utilities
- With the LOAD statement (DB-Access)
- From BYTE host variables ( Informix® ESQL/C )

You cannot use a quoted text string, number, or any other actual value to insert or update BYTE columns.

When you select a BYTE column, you can receive all or part of it. To retrieve it all, use the regular syntax for selecting a column. You can also select any part of a BYTE column by using subscripts, as the next example, which reads the first 75 bytes of the **cat\_picture** column associated with the catalog number 10001:

```
SELECT cat_picture [1,75] FROM catalog WHERE catalog_num = 10001
```

A built-in cast converts BYTE values to BLOB values. For more information, see the *Informix® Database Design and Implementation Guide*.

If you select a BYTE column using the DB-Access Interactive Schema Editor, only the string "<BYTE value>" is returned; no data value is displayed.

**Important:** If you try to return a BYTE column from a subquery, an error results, even if the column is not used in a Boolean expression nor with an aggregate.

## CHARACTER(n) data type

The CHARACTER data type is a synonym for CHAR.

## CHARACTER VARYING(m,r) data type

The CHARACTER VARYING data type stores a string of letters, digits, and symbols of varying length, where  $m$  is the maximum size of the column (in bytes) and  $r$  is the minimum number of bytes reserved for that column.

The CHARACTER VARYING data type complies with ANSI/ISO standard for SQL; the non-ANSI VARCHAR data type supports the same functionality. For more information, see the description of the VARCHAR type in [VARCHAR\(m,r\) data type on page 1655](#).

## CLOB data type

The CLOB data type stores any kind of text data in random-access chunks, called sbspaces. Text data can include text-formatting information, if this information is also textual, such as PostScript™, Hypertext Markup Language (HTML), Standard Graphic Markup Language (SGML), or Extensible Markup Language (XML) data.

The term *smart large object* refers to CLOB and BLOB data types. The CLOB data type supports special operations for character strings that are inappropriate for BLOB values. A CLOB value can be up to 4 terabytes ( $4 \times 2^{40}$  bytes) in length. The minimum amount of disk space allocated for smart large object data types is 512 bytes.

Use the BLOB data type (see [BLOB data type on page 1632](#)) for random access to binary data. For general information about the CLOB and BLOB data types, see [Smart large objects on page 1660](#).

The following SQL functions can perform operations on a CLOB column:

- FILETOCLOB copies a file into a CLOB column.
- LOTOFILE copies a CLOB (or BLOB) value into a file.
- LOCOPY copies a CLOB (or BLOB) value to a new smart large object.
- ENCRYPT\_DES or ENCRYPT\_TDES creates an encrypted BLOB value from a plain-text CLOB argument.
- DECRYPT\_BINAR or DECRYPT\_CHAR returns an unencrypted BLOB value from an encrypted BLOB argument (that ENCRYPT\_DES or ENCRYPT\_TDES created from a plain-text CLOB value).

For more information about these SQL functions, see the *Informix® Guide to SQL: Syntax*.

No casts exist for CLOB data. Therefore, the database server cannot convert data of the CLOB type to any other data type, except by using these encryption and decryption functions to return a BLOB. Within SQL, you are limited to the equality (=) comparison operation for CLOB data. To perform additional operations, you must use one of the application programming interfaces from within your client application.

## Multibyte characters with CLOB

### About this task

You can insert data into CLOB columns in the following ways:

- With the dload or onload utilities
- With the LOAD statement (DB-Access)
- From CLOB (**ifx\_lo\_t**) host variables (ESQL/C)

For examples of CLOB types, see the *Informix® Guide to SQL: Tutorial* and the *Informix® Database Design and Implementation Guide*.

With GLS, the following rules apply:

- Multibyte CLOB characters must be defined in the database locale.
- The CLOB data type is collated in code-set order.
- The database server handles code-set conversions for CLOB data.

For more information about database locales, collation order, and code-set conversion, see the *Informix® GLS User's Guide*.

## DATE data type

The DATE data type stores the calendar date. DATE data types require four bytes. A calendar date is stored internally as an integer value equal to the number of days since December 31, 1899.

Because DATE values are stored as integers, you can use them in arithmetic expressions. For example, you can subtract a DATE value from another DATE value. The result, a positive or negative INTEGER value, indicates the number of days that elapsed between the two dates. (You can use a UNITS DAY expression to convert the result to an INTERVAL DAY TO DAY data type.)

The following example shows the default display format of a DATE column:

```
mm/dd/yyyy
```

In this example, *mm* is the month (1-12), *dd* is the day of the month (1-31), and *yyyy* is the year (0001-9999). You can specify a different order of time units and a different time-unit separator than / (or no separator) by setting the **DBDATE** environment variable. For more information, see [DBDATE environment variable on page 1707](#).

In non-default locales, you can display dates in culture-specific formats. The locale and the **GL\_DATE** and **DBDATE** environment variables (as described in the next chapter) affect the display formatting of DATE values. They do not, however, affect the internal storage format for DATE columns in the database. For more information, see the *Informix® GLS User's Guide*.

## DEC data type

The DEC data type is a synonym for DECIMAL.

## DECIMAL

The DECIMAL data type can take two forms: DECIMAL(*p*) floating point and DECIMAL(*p,s*) fixed point.

In an ANSI-compliant database all DECIMAL numbers are fixed point.

By default, literal numbers that include a decimal ( . ) point are interpreted by the database server as DECIMAL values.

### DECIMAL(*p*) Floating Point

The DECIMAL data type stores decimal floating-point numbers up to a maximum of 32 significant digits, where *p* is the total number of significant digits (the *precision*).

Specifying precision is optional. If you specify no precision (*p*), DECIMAL is treated as DECIMAL(16), a floating-point decimal with a precision of 16 places. DECIMAL(*p*) has an absolute exponent range between  $10^{-130}$  and  $10^{124}$ .

If you declare a DECIMAL(*p*) column in an ANSI-compliant database, the scale defaults to DECIMAL(*p*, 0), meaning that only integer values can be stored in this data type.

In a database that is not ANSI-compliant, a DECIMAL(*p*) is a floating-point data type of a scale large enough to store the exponential notation for a value.

For example, the following calculation shows how many bytes of storage a DECIMAL(5) column requires in the default locale (where the decimal point occupies a single byte):

```

1 byte for the sign of the data value
1 byte for the 1st digit
1 byte for the decimal point
4 bytes for the rest of the digits (precision of 5 - 1)
1 byte for the e symbol
1 byte for the sign of the exponent
3 bytes for the exponent
-----
12 bytes total

```

Thus, "12345" in a DECIMAL(5) column is displayed as "12345.00000" (that is, with a scale of 6) in a database that is not ANSI-compliant.

### DECIMAL (*p,s*) Fixed Point

In fixed-point numbers, DECIMAL(*p,s*), the decimal point is fixed at a specific place, regardless of the value of the number. When you specify a column of this type, you declare its precision (*p*) as the total number of digits that it can store, from 1 to 32. You declare its *scale* (*s*) as the total number of digits in the fractional part (that is, to the right of the decimal point).

All numbers with an absolute value less than  $0.5 * 10^{-s}$  have the value zero. The largest absolute value of a DECIMAL(*p,s*) data type that you can store without an overflow error is  $10^{p-s} - 10^{-s}$ . A DECIMAL column typically stores numbers with

fractional parts that must be stored and displayed exactly (for example, rates or percentages). In an ANSI-compliant database, all DECIMAL numbers must have absolute values in the range  $10^{-32}$  to  $10^{+31}$ .

## DECIMAL Storage

The database server uses one byte of disk storage to store two digits of a decimal number, plus an additional byte to store the exponent and sign, with the first byte representing a sign bit and a 7-bit exponent in excess-65 format. The rest of the bytes express the mantissa as base-100 digits. The significant digits to the left of the decimal and the significant digits to the right of the decimal are stored in separate groups of bytes. At the maximum *precision* specification, DECIMAL(32,s) data types can store s-1 decimal digits to the right of the decimal point, if s is an odd number.

How the database server stores decimal numbers is illustrated in the following example. If you specify DECIMAL(6,3), the data type consists of three significant digits in the integral part and three significant digits in the fractional part (for instance, 123.456). The three digits to the left of the decimal are stored on 2 bytes (where one of the bytes only holds a single digit) and the three digits to the right of the decimal are stored on another 2 bytes, as [Figure 16: Schematic that illustrates the storage of digits in a decimal \(p,s\) value on page 1638](#) illustrates.

(The exponent byte is not shown.) With the additional byte required for the exponent and sign, DECIMAL(6,3) requires a total of 5 bytes of storage.

Figure 16. Schematic that illustrates the storage of digits in a decimal (p,s) value

You can use the following formulas (rounded down to a whole number of bytes) to calculate the byte storage (N) for a DECIMAL(p,s) data type (where N includes the byte that is required to store the exponent and the sign):

If the *scale* is odd:  $N = (\textit{precision} + 4) / 2$   
 If the *scale* is even:  $N = (\textit{precision} + 3) / 2$

For example, the data type DECIMAL(5,3) requires 4 bytes of storage ( $9/2$  rounded down equals 4).

There is one caveat to these formulas. The maximum number of bytes the database server uses to store a decimal value is 17. One byte is used to store the exponent and sign, leaving 16 bytes to store up to 32 digits of precision. If you specify a precision of 32 and an *odd* scale, however, you lose 1 digit of precision. Consider, for example, the data type DECIMAL(32,31). This decimal is defined as 1 digit to the left of the decimal and 31 digits to the right. The 1 digit to the left of the decimal requires 1 byte of storage. This leaves only 15 bytes of storage for the digits to the right of the decimal. The 15 bytes can accommodate only 30 digits, so 1 digit of precision is lost.

## DISTINCT data types

A DISTINCT type is a data type that is derived from a source type (called the base type).

A source type can be:

- A built-in type
- An existing DISTINCT type
- An existing named ROW type
- An existing opaque type

A DISTINCT type inherits from its source type the length and alignment on the disk. A DISTINCT type thus makes efficient use of the preexisting functionality of the database server.

When you create a DISTINCT data type, the database server automatically creates two explicit casts: one cast from the DISTINCT type to its source type and one cast from the source type to the DISTINCT type. A DISTINCT type based on a built-in source type does not inherit the built-in casts that are provided for the built-in type. A DISTINCT type does inherit, however, any user-defined casts that have been defined on the source type.

A DISTINCT type cannot be compared directly to its source type. To compare the two types, you must first explicitly cast one type to the other.

You must define a DISTINCT type in the database. Definitions of DISTINCT types are stored in the **sysxdtypes** system catalog table. The following SQL statements maintain the definitions of DISTINCT types in the database:

- The CREATE DISTINCT TYPE statement adds a DISTINCT type to the database.
- The DROP TYPE statement removes a previously defined DISTINCT type from the database.

For more information about the SQL statements mentioned above, see the *Informix® Guide to SQL: Syntax*. For information about casting DISTINCT data types, see [Casts for distinct types on page 1675](#). For examples that show how to create and register cast functions for a DISTINCT type, see the *Informix® Database Design and Implementation Guide*.

Size specifications in declarations of DISTINCT types whose base types are built-in character types can be affected by the SQL\_LOGICAL\_CHAR feature that is described in the section [Logical Character Semantics in Character Type Declarations on page 1658](#).

## DOUBLE PRECISION data types

The DOUBLE PRECISION keywords are a synonym for the FLOAT keyword.

---

### Related reference

[FLOAT\(n\) on page 1639](#)

## FLOAT(*n*)

The FLOAT data type stores double-precision floating-point numbers with up to 17 significant digits. FLOAT corresponds to IEEE 4-byte floating-point, and to the **double** data type in C. The range of values for the FLOAT data type is the same as the range of the C **double** data type on your computer.

You can use *n* to specify the precision of a FLOAT data type, but SQL ignores the precision. The value *n* must be a whole number between 1 and 14.

A column with the FLOAT data type typically stores scientific numbers that can be calculated only approximately. Because floating-point numbers retain only their most significant digits, the number that you enter in this type of column and the number the database server displays can differ slightly.

The difference between the two values depends on how your computer stores floating-point numbers internally. For example, you might enter a value of 1.1000001 into a FLOAT field and, after processing the SQL statement, the database server might display this value as 1.1. This situation occurs when a value has more digits than the floating-point number can store. In this case, the value is stored in its approximate form with the least significant digits treated as zeros.

FLOAT data types usually require 8 bytes of storage per value. Conversion of a FLOAT value to a DECIMAL value results in 17 digits of precision.

---

### Related reference

[DOUBLE PRECISION data types on page 1639](#)

## IDSSECURITYLABEL data type

The IDSSECURITYLABEL type stores a security label in a table that is protected by a label-based access control (LBAC) security policy.

Only a user who holds the **DBSECADM** role can create, alter, or drop a column of this data type. IDSSECURITYLABEL is a built-in DISTINCT OF VARCHAR(128) data type, but because its use is restricted to databases that implement label-based access control, it is not classified as a character data type. A table that is protected by a security policy can have only one IDSSECURITYLABEL column. A table that is not associated with any label-based security policy cannot include an IDSSECURITYLABEL column. You cannot encrypt the security label in a column of type IDSSECURITYLABEL.

For a discussion of security policies, security components, security labels, and other concepts of label-based access control (LBAC), see the Informix® Security Guide.

## INT data type

The INT data type is a synonym for INTEGER.

## INT8

The INT8 data type stores whole numbers that can range in value from  $-9,223,372,036,854,775,807$  to  $9,223,372,036,854,775,807$  [or  $-(2^{63}-1)$  to  $2^{63}-1$ ], for 18 or 19 digits of precision.

The number  $-9,223,372,036,854,775,808$  is a reserved value that cannot be used. The INT8 data type is typically used to store large counts, quantities, and so on.

HCL Informix® stores INT8 data in internal format that can require up to 10 bytes of storage.

Arithmetic operations and sort comparisons are performed more efficiently on integer data than on floating-point or fixed-point decimal data, but INT8 cannot store data with absolute values beyond  $|2^{63}-1|$ . If a value exceeds the numeric range of INT8, the database server does not store the value.

## INTEGER data type

The INTEGER data type stores whole numbers that range from  $-2,147,483,647$  to  $2,147,483,647$  for 9 or 10 digits of precision.

The number  $2,147,483,648$  is a reserved value and cannot be used. The INTEGER value is stored as a signed binary integer and is typically used to store counts, quantities, and so on.

Arithmetic operations and sort comparisons are performed more efficiently on integer data than on float or decimal data. INTEGER columns, however, cannot store absolute values beyond  $(2^{31}-1)$ . If a data value lies outside the numeric range of INTEGER, the database server does not store the value.

INTEGER data types require 4 bytes of storage per value.

## LIST(e) data type

The LIST data type is a collection type that can store ordered non-NULL elements of the same SQL data type.

The LIST data type supports, but does not require, duplicate element values. The elements of a LIST data type have ordinal positions. The LIST object must have a first element, which can be followed by a second element, and so on.

For unordered collection data types that do not support ordinal positions, see [MULTISET\(e\) data type on page 1644](#) and [SET\(e\) data type on page 1651](#). For complex data types that can store a set of values that includes different SQL data types, see [ROW Data Types on page 1669](#).

No more than 97 columns of the same table can be declared as LIST data types. (The same restriction applies to SET and MULTISET collection types.)

By default, the database server inserts new elements into a LIST object at the end of the set of elements. To support the ordinal position of a LIST, the INSERT statement provides the AT clause. This clause allows you to specify the position at which you want to insert a LIST element value. For more information, see the INSERT statement in the *Informix® Guide to SQL: Syntax*.

All elements in a LIST object have the same element type. To specify the element type, use the following syntax:

```
LIST(element_type NOT NULL)
```

The *element\_type* of a LIST can be any of the following data types:

- A built-in type, except SERIAL, SERIAL8, BIGSERIAL, BYTE, and TEXT
- A DISTINCT type
- An unnamed or named ROW type
- Another collection type
- An opaque type

You must specify the NOT NULL constraint for LIST elements. No other constraints are valid for LIST columns. For more information about the syntax of the LIST data type, see the *Informix® Guide to SQL: Syntax*.

You can use LIST in most contexts where any other data type is valid. For example:

- After the IN predicate in the WHERE clause of a SELECT statement to search for matching LIST values
- As an argument to the CARDINALITY or **mi\_collection\_card()** function to determine the number of elements in a LIST column

You *cannot* use LIST values as arguments to an aggregate function such as AVG, MAX, MIN, or SUM.

Just as with the other collection data types, you must use parentheses ( ( ) ) in data type declarations to delimit the set of elements of a LIST data type:

```
CREATE FUNCTION update_nums( list1 LIST (ROW (a VARCHAR(10),
                                     b VARCHAR(10),
                                     c INT) NOT NULL ));
```

In SQL expressions that include literal LIST values, however, you must use braces ( { } ) to delimit the set of elements of a LIST object, as in the examples that follow.

Two LIST values are equal if they have the same elements in the same order. The following are both examples of LIST objects, but their values are not equal. :

```
LIST{"blue", "green", "yellow"}
```

```
LIST{"yellow", "blue", "green"}
```

The above expressions are not equal because the values are not in the same order. To be equal, the second statement must be:

```
LIST{"blue", "green", "yellow"}
```

## LVARCHAR(m) data type

Use the LVARCHAR data type to create a column for storing variable-length character strings whose upper limit (*m*) can be up to 32,739 bytes.

This limit is much greater than the VARCHAR data type, which is used for character strings that are no longer than 255 bytes.

The LVARCHAR data type is implemented as a built-in opaque data type. You can access LVARCHAR columns in remote tables by using distributed queries across databases of the same or different HCL Informix® instances.

By default, the database server interprets quoted strings as LVARCHAR types. It also uses LVARCHAR for input and output casts for opaque data types.

The LVARCHAR data type stores opaque data types in the string (external) format. Each opaque type has an input support function and cast, which convert it from LVARCHAR to a form that database servers can manipulate. Each opaque type also has an output support function and cast, which convert it from its internal representation to LVARCHAR.

**Important:** When LVARCHAR is declared (with no size specification) as the data type of a column in a database table, the default maximum size is 2 KB (2048 bytes), but you can specify an explicit maximum length of up to 32,739 bytes. When LVARCHAR is used in I/O operations on an opaque data type, however, the maximum size is limited only by the operating system.

You cannot use the MEDIUM or HIGH options of the UPDATE STATISTICS statement to calculate distribution statistics on LVARCHAR columns.

Size specifications in LVARCHAR data type declarations can be affected by the SQL\_LOGICAL\_CHAR feature that is described in the section [Logical Character Semantics in Character Type Declarations on page 1658](#).

For more information about LVARCHAR, see the *Informix® User-Defined Routines and Data Types Developer's Guide*.

## MONEY(p,s) data type

The MONEY data type stores currency amounts.

Like the DECIMAL(p,s) data type, MONEY can store fixed-point numbers up to a maximum of 32 significant digits, where  $p$  is the total number of significant digits (the precision) and  $s$  is the number of digits to the right of the decimal point (the scale).

Unlike the DECIMAL data type, the MONEY data type is always treated as a fixed-point decimal number. The database server defines the data type MONEY( $p$ ) as DECIMAL( $p,2$ ). If the precision and scale are not specified, the database server defines a MONEY column as DECIMAL(16,2).

You can use the following formula (rounded down to a whole number of bytes) to calculate the byte storage for a MONEY data type:

If the *scale* is odd:  $N = (\textit{precision} + 4) / 2$   
 If the *scale* is even:  $N = (\textit{precision} + 3) / 2$

For example, a MONEY data type with a precision of 16 and a scale of 2 (MONEY(16,2)) requires 10 or  $(16 + 3)/2$ , bytes of storage.

In the default locale, client applications format values from MONEY columns with the following currency notation:

- A currency symbol: a dollar sign ( \$ ) at the front of the value
- A thousands separator: a comma ( , ) that separates every three digits in the integer part of the value
- A decimal point: a period ( . ) between the integer and fractional parts of the value

To change the format for MONEY values, change the **DBMONEY** environment variable. For valid **DBMONEY** settings, see [DBMONEY environment variable on page 1712](#).

The default value that the database server uses for scale is locale-dependent. The default locale specifies a default scale of two. For non-default locales, if the scale is omitted from the declaration, the database server creates MONEY values with a locale-specific scale.

The currency notation that client applications use is locale-dependent. If you specify a nondefault locale, the client uses a culture-specific format for MONEY values that might differ from the default U.S. English format in the leading (or trailing) currency symbol, thousands separator, and decimal separator, depending on what the locale files specify. For more information about locale dependency, see the *Informix® GLS User's Guide*.

## MULTISET(e) data type

The MULTISET data type is a collection type that stores a non-ordered set that can include duplicate element values.

The elements in a MULTISET have no ordinal position. That is, there is no concept of a first, second, or third element in a MULTISET. (For a collection type with ordinal positions for elements, see [LIST\(e\) data type on page 1641](#).)

All elements in a MULTISET have the same element type. To specify the element type, use the following syntax:

```
MULTISET(element_type NOT NULL)
```

The *element\_type* of a collection can be any of the following types:

- Any built-in type, except SERIAL, SERIAL8, BIGSERIAL, BYTE, and TEXT
- An unnamed or a named ROW type
- Another collection type or opaque type

You can use MULTISET anywhere that you use any other data type, unless otherwise indicated. For example:

- After the IN predicate in the WHERE clause of a SELECT statement to search for matching MULTISET values
- As an argument to the CARDINALITY or **mi\_collection\_card()** function to determine the number of elements in a MULTISET column

You *cannot* use MULTISET values as arguments to an aggregate function such as AVG, MAX, MIN, or SUM.

You must specify the NOT NULL constraint for MULTISET elements. No other constraints are valid for MULTISET columns. For more information about the MULTISET collection type, see the *Informix® Guide to SQL: Syntax*.

Two multiset data values are equal if they have the same elements, even if the elements are in different positions within the set. The following examples are both multiset values but are not equal:

```
MULTISET {"blue", "green", "yellow"}
MULTISET {"blue", "green", "yellow", "blue"}
```

The following multiset values are equal:

```
MULTISET {"blue", "green", "blue", "yellow"}
MULTISET {"blue", "green", "yellow", "blue"}
```

No more than 97 columns of the same table can be declared as MULTISSET data types. (The same restriction applies to SET and LIST collection types.)

## Named ROW

See [ROW data type, Named on page 1646](#).

## NCHAR(n) data type

The NCHAR data type stores fixed-length character data. The data can be a string of single-byte or multibyte letters, digits, and other symbols that are supported by the code set of the database locale.

The main difference between CHAR and NCHAR data types is the collating order.

The collation order of the CHAR data type follows the code-set order, but the collating order of the NCHAR data type can be a localized order, if **DB\_LOCALE** (or SET COLLATION) specifies a locale that defines a localized order for collation.

Size specifications in NCHAR data type declarations can be affected by the SQL\_LOGICAL\_CHAR configuration parameter that is described in the section [Logical Character Semantics in Character Type Declarations on page 1658](#).

In databases that are created with the NLSCASE INSENSITIVE property, operations on NCHAR strings ignore letter case, ordering data values without respect to or preference for letter case. For example, the NCHAR string "IDS" might precede or follow "IdS" or "iDs" in the collated list that a query returns, depending on the order in which these data strings are retrieved, because all of the following NCHAR strings are treated as duplicate values:

```
"ids" "IDS" "idS" "IDs" "IdS" "iDs" "iDS" "Ids"
```

## NUMERIC(p,s) data type

The NUMERIC data type is a synonym for fixed-point DECIMAL.

## NVARCHAR(m,r) data type

The NVARCHAR data type stores strings of varying lengths. The string can include digits, symbols, and both single-byte and (in some locales) multibyte characters.

The main difference between VARCHAR and NVARCHAR data types is the collation order. Collation of VARCHAR data follows code-set order, but NVARCHAR collation can be locale specific, if **DB\_LOCALE** (or SET COLLATION) has specified a locale that defines a localized order for collation. (The section [Collating VARCHAR Values on page 1656](#) describes an exception.)

A column declared as NVARCHAR, without parentheses or parameters, has a maximum size of one byte, and a reserved size of zero.

The first parameter in NVARCHAR data type declarations can be affected by the SQL\_LOGICAL\_CHAR configuration parameter that is described in the section [Logical Character Semantics in Character Type Declarations on page 1658](#).

No more than 195 columns of the same table can be NVARCHAR data types.

In databases that are created with the NLSCASE INSENSITIVE property, operations on NVARCHAR strings ignore letter case, ordering data values without respect to or preference for letter case. For example, the NVARCHAR string "IBM" might precede or follow "IbM" or "iBm" in the collated list that a query returns, depending on the order in which these data strings are retrieved, because all of the following NVARCHAR strings are treated as duplicate values:

```
"ibm" "IBM" "iBm" "IBm" "IbM" "iBM" "iBM" "Ibm"
```

## OPAQUE data types

An OPAQUE type is a data type for which you must provide information to the database server.

You must provide this information:

- A data structure for how the data values are stored on disk
- Support functions to determine how to convert between the disk storage format and the user format for data entry and display
- Secondary access methods that determine how the index on this data type is built, used, and manipulated
- User functions that use the data type
- A system catalog entry to register the OPAQUE type in the database

The internal structure of an OPAQUE type is not visible to the database server and can only be accessed through user-defined routines. Definitions for OPAQUE types are stored in the **sysxdtypes** system catalog table. These SQL statements maintain the definitions of OPAQUE types in the database:

- The CREATE OPAQUE TYPE statement registers a new OPAQUE type in the database.
- The DROP TYPE statement removes a previously defined OPAQUE type from the database.

For more information about the above-mentioned SQL statements, see the *Informix® Guide to SQL: Syntax*. For information about how to create OPAQUE types and an example of an OPAQUE type, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

## REAL data type

The REAL data type is a synonym for SMALLFLOAT.

## ROW data type, Named

A named ROW data type must be declared with a name. This SQL identifier must be unique among data type names within the same database.

(An unnamed ROW type is a ROW type that contains fields but has no user-defined name.) Only named ROW types support data type inheritance. For more information, see [ROW Data Types on page 1669](#).

### Defining named ROW types

You must declare and register in the database a new named ROW type by using the CREATE ROW TYPE statement of SQL. Definitions for named ROW types are stored in the **sysxdtypes** system catalog table.

The fields of a ROW data type can be any built-in data type or UDT, but TEXT or BYTE fields of a ROW type are valid in typed tables only. If you want to assign a ROW type to a column in the CREATE TABLE or ALTER TABLE statements, its elements cannot be TEXT or BYTE data types.

In general, the data type of a field of a ROW type can be any of these types:

- A built-in type (except for the TEXT or BYTE data types)
- A collection type (LIST, MULTISET, or SET)
- A distinct type
- Another named or unnamed ROW type
- An opaque type

These SQL statements maintain the definitions of named ROW data types:

- The CREATE ROW TYPE statement adds a named ROW type to the database.
- The DROP ROW TYPE statement removes a previously defined named ROW type from the database.

No more than 195 columns of the same table can be named ROW types.

For details about these SQL syntax statements, see the *Informix® Guide to SQL: Syntax*. For examples of how to create and use named ROW types, see the *Informix® Database Design and Implementation Guide*.

### Equivalence and named ROW types

No two named ROW types can be equal, even if they have identical structures, because they have different names. For example, the following named ROW types have the same structure (the same number of fields and the same order of data types of fields within the row) but they are not equal:

```
name_t (lname CHAR(15), initial CHAR(1), fname CHAR(15))
emp_t (lname CHAR(15), initial CHAR(1), fname CHAR(15))
```

A Boolean equality condition like `name_t = emp_t` always evaluates to FALSE if both of the operands are different named ROW types.

### Named ROW types and inheritance

Named ROW types can be part of a type-inheritance hierarchy. One named ROW type can be the parent (or supertype) of another named ROW type. A subtype in a hierarchy inherits all the properties of its supertype. Type inheritance is explained

in the CREATE ROW TYPE statement in the *Informix® Guide to SQL: Syntax* and in the *Informix® Database Design and Implementation Guide*.

## Typed tables

Tables that are part of an inheritance hierarchy must be typed tables. Typed tables are tables that have been assigned a named ROW type. For the syntax you use to create typed tables, see the CREATE TABLE statement in the *Informix® Guide to SQL: Syntax*. Table inheritance and its relation to type inheritance is also explained in that section. For information about how to create and use typed tables, see the *Informix® Database Design and Implementation Guide*.

## ROW data type, Unnamed

An unnamed ROW type contains fields but has no user-declared name. An unnamed ROW type is defined by its structure.

Two unnamed ROW types are equal if they have the same structure (meaning the ordered list of the data types of the fields). If two unnamed ROW types have the same number of fields, and if the order of the data type of each field in one ROW type matches the order of data types of the corresponding fields in the other ROW data type, then the two unnamed ROW data types are equal.

For example, the following unnamed ROW types are equal:

```
ROW (lname char(15), initial char(1) fname char(15))
ROW (dept char(15), rating char(1) name char(15))
```

The following ROW types have the same number of fields and the same data types, but are not equal, because their fields are not in the same order:

```
ROW (x integer, y varchar(20), z real)
ROW (x integer, z real, y varchar(20))
```

A field of an unnamed ROW type can be any of the following data types:

- A built-in type
- A collection type
- A distinct type
- Another ROW type
- An opaque type

Unnamed ROW types cannot be used in typed tables or in type inheritance hierarchies. For more information about unnamed ROW types, see the *Informix® Guide to SQL: Syntax* and the *Informix® Database Design and Implementation Guide*.

## Creating unnamed ROW types

### About this task

You can create an unnamed ROW type in several ways:

- You can declare an unnamed ROW type using the ROW keyword. Each field in a ROW can have a different field type. To specify the field type, use the following syntax:

```
ROW (field_name field_type, ...)
```

The *field\_name* must conform to the rules for SQL identifiers. (See the Identifier section in the *Informix® Guide to SQL: Syntax*.)

- To generate an unnamed ROW type, use the ROW keyword as a constructor with a series of values. A corresponding unnamed ROW type is created, using the default data types of the specified values.

For example, the following declaration:

```
ROW(1, 'abc', 5.30)
```

defines this unnamed ROW data type:

```
ROW (x INTEGER, y VARCHAR, z DECIMAL)
```

- You can create an unnamed ROW type by an implicit or explicit cast from a named ROW type or from another unnamed ROW type.
- The rows of any table (except a table defined on a named ROW type) are unnamed ROW types.

No more than 195 columns of the same table can be unnamed ROW types.

## Inserting Values into Unnamed ROW Type Columns

### About this task

When you specify field values for an unnamed ROW type, list the field values after the constructor and between parentheses. For example, suppose you have an unnamed ROW-type column. The following INSERT statement adds one group of field values to this ROW column:

```
INSERT INTO table1 VALUES (ROW(4, 'abc'))
```

You can specify a ROW column in the IN predicate in the WHERE clause of a SELECT statement to search for matching ROW values. For more information, see the Condition section in the *Informix® Guide to SQL: Syntax*.

## SERIAL(n) data type

The SERIAL data type stores a sequential integer, of the INT data type, that is automatically assigned by the database server when a new row is inserted.

The default serial starting number is 1, but you can assign an initial value, *n*, when you create or alter the table.

- You must specify a positive number for the starting number.
- If you specify zero (0) for the starting number, the value that is used is the maximum positive value that already exists in the SERIAL column + 1.

The maximum value for SERIAL is 2,147,483,647. If you assign a number greater than 2,147,483,647, you receive a syntax error. Use the SERIAL8 or BIGSERIAL data type, rather than SERIAL, if you need a larger range.

A table can have no more than one SERIAL column, but it can have a SERIAL column and either a SERIAL8 column or a BIGSERIAL column.

SERIAL values in a column are not automatically unique. You must apply a unique index or primary key constraint to this column to prevent duplicate serial numbers. If you use the interactive schema editor in DB-Access to define the table, a unique index is applied automatically to a SERIAL column.

SERIAL numbers might not be consecutive, because of concurrent users, rollbacks, and other factors.

The DEFINE *variable* LIKE *column* syntax of SPL for indirect typing declares a variable of the INTEGER data type if *column* is a SERIAL data type.

After a number is assigned, it cannot be changed. You can insert a value into a SERIAL column (using the INSERT statement) or reset a serial column (using the ALTER TABLE statement), if the new value does not duplicate any existing value in the column. To insert into a SERIAL column, your database server increments by one the previous value (or the reset value, if that is larger) and assigns the result as the entered value. If ALTER TABLE has reset the next value of a SERIAL column to a value smaller than values already in that column, however, the next value follows this formula:

$$(\text{maximum existing value in SERIAL column}) + 1$$

For example, if you reset the serial value of **customer.customer\_num** to 50, when the largest existing value is 128, the next assigned number will be 129. For more details on SERIAL data entry, see the *Informix® Guide to SQL: Syntax*.

A SERIAL column can store unique codes such as order, invoice, or customer numbers. SERIAL data values require four bytes of storage, and have the same precision as the INTEGER data type. For details of another way to assign unique whole numbers to each row of a database table, see the CREATE SEQUENCE statement in *Informix® Guide to SQL: Syntax*.

## SERIAL8(n) data type

The SERIAL8 data type stores a sequential integer, of the INT8 data type, that is assigned automatically by the database server when a new row is inserted.

The SERIAL8 data type behaves like the SERIAL data type, but with a larger range. For more information about how to insert values into SERIAL8 columns, see the *Informix® Guide to SQL: Syntax*.

A SERIAL8 data column is commonly used to store large, unique numeric codes such as order, invoice, or customer numbers. SERIAL8 data values have the same precision and storage requirements as INT8 values (page [INT8 on page 1640](#)).

The default serial starting number is 1, but you can assign an initial value, *n*, when you create or alter the table.

- You must specify a positive number for the starting number.
- If you specify zero (0) for the starting number, the value that is used is the maximum positive value that already exists in the SERIAL8 column + 1.

A table can have no more than one SERIAL column, but it can have a SERIAL column and either a SERIAL8 column or a BIGSERIAL column.

SERIAL8 values in a column are not automatically unique. You must apply a unique index or primary key constraint to this column to prevent duplicate serial numbers. If you use the interactive schema editor in DB-Access to define the table, a unique index is applied automatically to a SERIAL8 column.

SERIAL8 numbers might not be consecutive, because of concurrent users, rollbacks, and other factors.

The DEFINE *variable* LIKE *column* syntax of SPL for indirect typing declares a variable of the INTEGER data type if *column* is a SERIAL8 data type.

For more information, see [Assigning a Starting Value for SERIAL8 on page 1651](#). For information about using the SERIAL8 data type with the INT8 or BIGINT data type, see [Using SERIAL8 and BIGSERIAL with INT8 or BIGINT on page 1632](#)

## Assigning a Starting Value for SERIAL8

The default serial starting number is 1, but you can assign an initial value, *n*, when you create or alter the table. To start the values at *n* in a SERIAL8 column of a table, give the value *n* for the SERIAL8 column when you insert rows into that table.

The database server will assign the value 1 to the SERIAL8 column of the first row of the table. The largest SERIAL8 value that you can assign is  $2^{63}-1$  (9,223,372,036,854,775,807). If you assign a value greater than this, you receive a syntax error.

When the database server generates a SERIAL8 value of this maximum number, it wraps around and starts generating values beginning at 1.

After a nonzero SERIAL8 number is assigned, it cannot be changed. You can, however, insert a value into a SERIAL8 column (using the INSERT statement) or reset the SERIAL8 value *n* (using the ALTER TABLE statement), if that value does not duplicate any existing values in the column.

When you insert a number into a SERIAL8 column or reset the next value of a SERIAL8 column, your database server assigns the next number in sequence to the number entered. If you reset the next value of a SERIAL8 column to a value that is less than the values already in that column, however, the next value is computed using the following formula:

$$\text{maximum existing value in SERIAL8 column} + 1$$

For example, if you reset the SERIAL8 value of the **customer\_num** column in the **customer** table to 50, when the highest-assigned customer number is 128, the next customer number assigned is 129.

For information about using the SERIAL8 data type with the INT8 or BIGINT data type, see [Using SERIAL8 and BIGSERIAL with INT8 or BIGINT on page 1632](#)

## SET(e) data type

The SET data type is an unordered collection type that stores unique elements

Duplicate element values are not valid as explained in *Informix® Guide to SQL: Syntax*. (For a collection type that supports duplicate values, see the description of MULTISET in [MULTISET\(e\) data type on page 1644](#).)

No more than 97 columns of the same table can be declared as SET data types. (The same restriction also applies to MULTISET and LIST collection types.)

The elements in a SET have no ordinal position. That is, no construct of a first, second, or third element in a SET exists. (For a collection type with ordinal positions for elements, see [LIST\(e\) data type on page 1641](#).) All elements in a SET have the same element type. To specify the element type, use this syntax:

```
SET(element_type NOT NULL)
```

The *element\_type* of a collection can be any of the following types:

- A built-in type, except SERIAL, SERIAL8, BIGSERIAL, BYTE, and TEXT
- A named or unnamed ROW type
- Another collection type
- An opaque type

You must specify the NOT NULL constraint for SET elements. No other constraints are valid for SET columns. For more information about the syntax of the SET collection type, see the *Informix® Guide to SQL: Syntax*.

You can use SET anywhere that you use any other data type, unless otherwise indicated. For example:

- After the IN predicate in the WHERE clause of a SELECT statement to search for matching SET values
- As an argument to the CARDINALITY or **mi\_collection\_card()** function to determine the number of elements in a SET column

SET values are not valid as arguments to an aggregate function such as AVG, MAX, MIN, or SUM. For more information, see the Condition and Expression sections in the *Informix® Guide to SQL: Syntax*.

The following examples declare two sets. The first statement declares a set of integers and the second declares a set of character elements.

```
SET(INTEGER NOT NULL)
SET(CHAR(20) NOT NULL)
```

The following examples construct the same sets from value lists:

```
SET{1, 5, 13}
SET{"Oakland", "Menlo Park", "Portland", "Lenexa"}
```

In the following example, a SET constructor function is part of a CREATE TABLE statement:

```
CREATE TABLE tab
(
  c CHAR(5),
  s SET(INTEGER NOT NULL)
);
```

The following set values are equal:

```
SET{"blue", "green", "yellow"}
SET{"yellow", "blue", "green"}
```

## SMALLFLOAT

The SMALLFLOAT data type stores single-precision floating-point numbers with approximately nine significant digits.

SMALLFLOAT corresponds to the **float** data type in C. The range of values for a SMALLFLOAT data type is the same as the range of values for the C **float** data type on your computer.

A SMALLFLOAT data type column typically stores scientific numbers that can be calculated only approximately. Because floating-point numbers retain only their most significant digits, the number that you enter in this type of column and the number the database displays might differ slightly depending on how your computer stores floating-point numbers internally.

For example, you might enter a value of 1.1000001 in a SMALLFLOAT field and, after processing the SQL statement, the application might display this value as 1.1. This difference occurs when a value has more digits than the floating-point number can store. In this case, the value is stored in its approximate form with the least significant digits treated as zeros.

SMALLFLOAT data types usually require four bytes of storage. Conversion of a SMALLFLOAT value to a DECIMAL value results in nine digits of precision.

## SMALLINT data type

The SMALLINT data type stores small whole numbers that range from  $-32,767$  to  $32,767$ . The maximum negative number,  $-32,768$ , is a reserved value and cannot be used.

The SMALLINT value is stored as a signed binary integer.

Integer columns typically store counts, quantities, and so on. Because the SMALLINT data type requires only two bytes per value, arithmetic operations are performed efficiently. SMALLINT, however, stores only a limited range of values, compared to other built-in numeric data types. If a number is outside the range of the minimum and maximum SMALLINT values, the database server does not store the data value, but instead issues an error message.

## TEXT data type

The TEXT data type stores any kind of text data. It can contain both single-byte and multibyte characters that the locale supports. The term *simple large object* refers to an instance of a TEXT or BYTE data type.

A TEXT column has a theoretical limit of  $2^{31}$  bytes (two gigabytes) and a practical limit that your available disk storage determines. No more than 195 columns of the same table can be declared as TEXT data types. The same restriction also applies to BYTE data types.

You can store, retrieve, update, or delete the value in a TEXT column.

You can use TEXT operands in Boolean expressions only when you are testing for NULL values with the IS NULL or IS NOT NULL operators.

You can use the following methods, which can load rows or update fields, to insert TEXT data:

- With the **dbload** or **onload** utilities
- With the LOAD statement (DB-Access)
- From TEXT host variables (ESQL)

A built-in cast exists to convert TEXT objects to CLOB objects. For more information, see the *Informix® Database Design and Implementation Guide*.

Strings of the TEXT data type are collated in code-set order. For more information about collating orders, see the *Informix® GLS User's Guide*.

### Selecting data in a TEXT column

When you select a TEXT column, you can receive all or part of it. To retrieve it all, use the regular syntax for selecting a column. You can also select any part of a TEXT column by using subscripts, as this example shows:

```
SELECT cat_descr [1,75] FROM catalog WHERE catalog_num = 10001
```

The SELECT statement reads the first 75 bytes of the **cat\_descr** column associated with the **catalog\_num** value 10001.

### Loading data into a TEXT column

You can use the LOAD statement to insert data into a table. For example, the `inp.txt` file contains the following information:

```
1|aaaaa|
2|bbbbb|
3|cccccc|
```

To load this data into the `blobtab` table use the following statement:

```
LOAD FROM inp.txt INSERT INTO blobtab;
```

### Limitations

You cannot use TEXT operands in arithmetic or string expressions, nor can you assign literals to TEXT columns in the SET clause of the UPDATE statement.

You also cannot use TEXT values in any of the following ways:

- With aggregate functions
- With the IN clause
- With the MATCHES or LIKE clauses
- With the GROUP BY clause
- With the ORDER BY clause

You cannot use a quoted text string, number, or any other actual value to insert or update TEXT columns.

You cannot use the MEDIUM or HIGH options of the UPDATE STATISTICS statement to calculate distribution statistics on TEXT columns.

**Important:** An error results if you try to return a TEXT column from a subquery, even if no TEXT column is used in a comparison condition or with the IN predicate.

## Nonprintable Characters in TEXT Values

TEXT columns typically store documents, program source files, and so on. In the default U.S. English locale, data objects of type TEXT can contain a combination of printable ASCII characters and the following control characters:

- Tab (CTRL-I)
- New line (CTRL-J)
- New page (CTRL-L)

Both printable and nonprintable characters can be inserted in text columns. HCL Informix® products do not do any checking of data values that are inserted in a column of the TEXT data type. (Applications might have difficulty, however, in displaying TEXT values that include non-printable characters.) For detailed information about entering and displaying nonprintable characters, see [Nonprintable Characters with CHAR](#).

## Unnamed ROW

See [ROW data type, Unnamed on page 1648](#).

## VARCHAR(m,r) data type

The VARCHAR data type stores character strings of varying length that contain single-byte and (if the locale supports them) multibyte characters, where  $m$  is the maximum size (in bytes) of the column and  $r$  is the minimum number of bytes reserved for that column.

A column declared as VARCHAR without parentheses or parameters has a maximum size of one byte, and a reserved size of zero.

The VARCHAR data type is the HCL Informix® implementation of a character varying data type. The ANSI standard data type for varying-length character strings is CHARACTER VARYING.

The size of the maximum size ( $m$ ) parameter of a VARCHAR column can range from 1 to 255 bytes. If you are placing an index on a VARCHAR column, the maximum size is 254 bytes. You can store character strings that are shorter, but not longer, than the  $m$  value that you specify.

Specifying the minimum reserved space ( $r$ ) parameter is optional. This value can range from 0 to 255 bytes but must be less than the maximum size ( $m$ ) of the VARCHAR column. If you do not specify any minimum value, it defaults to 0. You should specify this parameter when you initially intend to insert rows with short or NULL character strings in the column but later expect the data to be updated with longer values.

For variable-length strings longer than 255 bytes, you can use the LVARCHAR data type, whose upper limit is 32,739 bytes, instead of VARCHAR.

In an index based on a VARCHAR column (or on a NVARCHAR column), each index key has a length that is based on the data values that are actually entered, rather than on the declared maximum size of the column. (See, however, [IFX\\_PAD\\_VARCHAR environment variable on page 1730](#) for information about how you can configure the effective size of VARCHAR and NVARCHAR data strings that HCL Informix® sends or receives.)

When you store a string in a VARCHAR column, only the actual data characters are stored. The database server does not strip a VARCHAR string of any user-entered trailing blanks, nor pad a VARCHAR value to the declared length of the column. If you specify a reserved space (*r*), but some data strings are shorter than *r* bytes, some space reserved for rows goes unused.

VARCHAR values are compared to other VARCHAR values (and to other character-string data types) in the same way that CHAR values are compared. The shorter value is padded on the right with blank spaces until the values have equal lengths; then they are compared for the full length.

No more than 195 columns of the same table can be VARCHAR data types.

### Nonprintable Characters with VARCHAR

Nonprintable VARCHAR characters are entered, displayed, and treated in the same way that nonprintable characters in CHAR values are treated. For details, see Nonprintable Characters with CHAR.

### Storing Numeric Values in a VARCHAR Column

When you insert a numeric value in a VARCHAR column, the stored value does not get padded with trailing blanks to the maximum length of the column. The number of digits in a numeric VARCHAR value is the number of characters that are required to store that value. For example, in the next example, the value stored in table **mytab** is **1**.

```
create table mytab (col1 varchar(10));
insert into mytab values (1);
```

**Tip:** VARCHAR treats C *null* (binary 0) and string terminators as termination characters for nonprintable characters.

In some East Asian locales, VARCHAR data types can store multibyte characters if the database locale supports a multibyte code set. If you store multibyte characters, make sure to calculate the number of bytes needed. For more information, see the *Informix® GLS User's Guide*.

### Multibyte Characters with VARCHAR

The first parameter in VARCHAR data type declarations can be affected by the SQL\_LOGICAL\_CHAR feature that is described in the section [Logical Character Semantics in Character Type Declarations on page 1658](#).

### Collating VARCHAR Values

The main difference between the NVARCHAR and the VARCHAR data types (like the difference between CHAR and NCHAR) is the difference in collating order. In general, collation of VARCHAR (like CHAR and LVARCHAR) values is in the order of the characters as they exist in the code set.

An exception is the MATCHES operator, which applies a localized collation to NVARCHAR and VARCHAR values (and to CHAR, LVARCHAR, and NCHAR values) if you use bracket ( [ ] ) symbols to define ranges when **DB\_LOCALE** (or SET COLLATION) has specified a localized collating order. For more information, see the *Informix® GLS User's Guide*.

## Built-In Data Types

HCL Informix® supports the following built-in data types.

| Category              | Data Types   |
|-----------------------|--|
| Character             | CHAR, CHARACTER VARYING, LVARCHAR, NCHAR, NVARCHAR, VARCHAR, IDSSECURITYLABEL                  |
| Large-object          | Simple-large-object types: BYTE, TEXT Smart-large-object types: BLOB, CLOB                     |
| Logical               | BOOLEAN  |
| Multirepresentational | <a href="#">BSON and JSON built-in opaque data types on page</a>                               |
| Numeric               | BIGINT, BIGSERIAL, DECIMAL, FLOAT, INT8, INTEGER, MONEY, SERIAL, SERIAL8, SMALLFLOAT, SMALLINT |
| Time                  | DATE, DATETIME, INTERVAL   |

### Related reference

[Summary of data types on page 1626](#)

## Character Data Types

The character data types store string values.

### Built-in Character Types

**Table 76. Attributes of built-in character data types**

|                       | Size (in bytes) | Default        | Reserved       | Collation | Length   |
|-----------------------|-----------------|----------------|----------------|-----------|----------|
| <b>CHAR(n)</b>        | 1 to 32,767     | 1 byte         | None           | Code set  | Fixed    |
| <b>NCHAR(n)</b>       | 1 to 32,767     | 1 byte         | None           | Localized | Fixed    |
| <b>VARCHAR(m, r)</b>  | 1 to 255        | 0 for <b>r</b> | 0 to 255 bytes | Code set  | Variable |
| <b>NVARCHAR(m, r)</b> | 1 to 255        | 0 for <b>r</b> | 0 to 255 bytes | Localized | Variable |
| <b>LVARCHAR(m)</b>    | 1 to 32,739     | 2048 bytes     | None           | Code set  | Variable |

The database server also uses LVARCHAR to represent the external format of opaque data types. In I/O operations of the database server, LVARCHAR data values have no upper limit on their size, apart from file size restrictions or limits of your operating system or hardware resources.

## Logical Character Semantics in Character Type Declarations

HCL Informix® supports a configuration parameter, `SQL_LOGICAL_CHAR`, whose setting can instruct the SQL parser to interpret the maximum size of character columns in data type declarations of the `CREATE TABLE` or `ALTER TABLE` statements as logical characters, rather than in units of bytes.

When a database is created, the current `SQL_LOGICAL_CHAR` setting for the database server is recorded in the **systables** table of the system catalog. The feature has no effect on tables that are subsequently created or altered in the database if the setting is `OFF` or `1`.

In a database where the `SQL_LOGICAL_CHAR` setting is `ON` or is a digit between 2, 3, or 4, however, the SQL parser interprets explicit and implicit size declarations as logical characters in declarations of SPL variables and declarations of columns in database tables for the following character types:

- `CHAR` and `CHARACTER`
- `CHARACTER VARYING` and `VARCHAR`
- `LVARCHAR`
- `NCHAR`
- `NVARCHAR`
- `DISTINCT` types of the data types listed above
- `DISTINCT` types of those `DISTINCT` types
- `ROW` data type fields of the types listed above .
- `LIST`, `MULTISET`, and `SET` elements of the types listed above.

This feature has no effect on the maximum storage size limits for the character types listed in the previous table. For databases that use a multibyte locale, however, it can reduce the risk of data truncation when a string is inserted into a character column or assigned to a character variable.

For example, if 4 is the `SQL_LOGICAL_CHAR` setting for the database, then a `VARCHAR(10, 5)` specification is interpreted as requesting a maximum of 40 bytes of storage, with 5 of these bytes reserved, creating a `VARCHAR(40, 5)` data type in standard SQL notation, rather than what was specified in the declaration.

The reserve size parameters of `VARCHAR` and `NVARCHAR` data types are not affected by the `SQL_LOGICAL_CHAR` setting, because the minimum size of a multibyte character is 1 byte. In this example, the minimum size of 5 multibyte characters is 5 bytes, a size that remains unchanged.

See the description of the `SQL_LOGICAL_CHAR` configuration parameter in the for more information about the effect of the `SQL_LOGICAL_CHAR` setting in databases whose **DB\_LOCALE** specifies a multibyte locale. For additional information about multibyte locales and logical characters, see the *Informix® GLS User's Guide*.

## IDSSECURITYLABEL

HCL Informix® also supports the `IDSSECURITYLABEL` data type for systems that implement label-based access control (LBAC). This built-in data type can be formally classified as a character type, because it is defined as a `DISTINCT OF VARCHAR(128)` data type, but only users who hold the **DBSECADM** role can declare this data type in DDL operations. It supports the LBAC security feature, rather than functioning as a general-purpose character type.

## Data Type Promotion

For some string-manipulation operations of HCL Informix®, the five built-in character data types listed above support data type promotion, in order to reduce the risk of string operations failing because a returned string is too large to be stored in an NVARCHAR or VARCHAR column or program variable. See the topic "Return Types from CONCAT and String Manipulation Functions" in *Informix® Guide to SQL: Syntax* for details of data type promotion among HCL Informix® character types.

## National Language Support

The NCHAR and NVARCHAR types are sometimes called National Language Support data types because of their support for localized collation. Because columns of type VARCHAR or NVARCHAR have no default size, you must specify a size (no greater than 255) in their declaration. For VARCHAR or NVARCHAR columns on which an index is defined, the maximum size is 254 bytes.

## NLSCASE INSENSITIVE Databases

In databases created with the `NLSCASE INSENSITIVE` keyword option, operations on data strings of the NCHAR or NVARCHAR types makes no distinction between uppercase and lowercase variants of the same letter. Rows are stored in NCHAR or NVARCHAR columns in the letter case in which characters were loaded, but data strings that consist of the same letters in the same sequence are evaluated as duplicates, even if the case of some letters is not identical. For example, the three NCHAR strings `"ABC"` and `"AbC"` and `"abc"` are treated as duplicates. Other built-in character types, including CHAR, LVARCHAR, and VARCHAR, follow the default case-sensitive rules, so that the same three strings in a CHAR column evaluate to distinct values.

Databases with the `NLSCASE INSENSITIVE` property also ignore the letter case of DISTINCT data types whose base types are NCHAR or NVARCHAR, as well as NCHAR or NVARCHAR fields in named or unnamed ROW types, and NCHAR or NVARCHAR elements of COLLECTION data types, including LIST, SET, or MULTISSET.

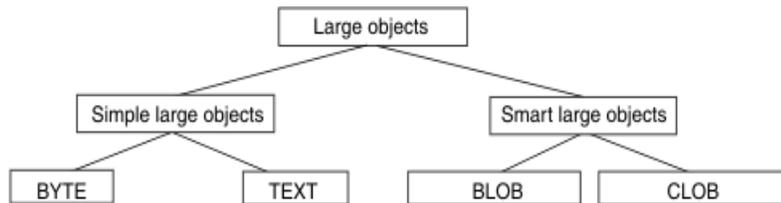

In a database that is insensitive to the letter case of NCHAR or NVARCHAR values, string manipulation operations might produce unexpected results, if they implicitly cast CHAR, LVARCHAR, or VARCHAR operands or arguments to NCHAR or NVARCHAR data types. In some contexts, the operation can return a duplicate string, despite letter case variations that the database server would not have treated as duplicates for the original data types.

## Large-Object Data Types

A large object is a data object that is logically stored in a table column but physically stored independent of the column. Large objects are stored separate from the table because they typically store a large amount of data. Separation of this data from the table can increase performance.

[Figure 17: Large-Object Data Types on page 1660](#) shows the large-object data types.

Figure 17. Large-Object Data Types

Only HCL Informix® supports BLOB and CLOB data types.

For the relative advantages and disadvantages of simple and smart large objects, see the *Informix® Database Design and Implementation Guide*.

## Simple Large Objects

Simple large objects are a category of large objects that have a theoretical size limit of  $2^{31}$  bytes and a practical limit that your disk capacity determines. HCL Informix® supports these simple-large-object data types:

### BYTE

Stores binary data. For more detailed information about this data type, see the description on page [BYTE data type on page 1633](#).

### TEXT

Stores text data. For more detailed information about this data type, see the description on page [TEXT data type on page 1653](#).

No more than 195 columns of the same table can be declared as BYTE or TEXT data types. Unlike smart large objects, simple large objects do not support random access to the data. When you transfer a simple large object between a client application and the database server, you must transfer the entire BYTE or TEXT value. If the data cannot fit into memory, you must store the data value in an operating-system file and then retrieve it from that file.

The database server stores simple large objects in *blobspaces*. A *blobspace* is a logical storage area that contains one or more chunks that only store BYTE and TEXT data. For information about how to define blobspaces, see your *Informix® Administrator's Guide*.

## Smart large objects

Smart large objects are a category of large objects that support random access to the data, and that are generally recoverable.

The random access feature allows you to seek and read through the smart large object as if it were an operating-system file.

Smart large objects are also useful for opaque data types with large storage requirements. (See the description of opaque data types in [Opaque Data Types on page 1670](#).) They have a theoretical size limit of  $2^{42}$  bytes and a practical limit that your disk capacity determines.

HCL Informix® supports the following smart-large-object data types:

### **BLOB**

Stores binary data. For more information about this data type, see the description on page [BLOB data type on page 1632](#).

### **CLOB**

Stores text data. For more information about this data type, see [CLOB data type on page 1635](#).

HCL Informix® stores smart large objects in *sbspaces*. An *sbspace* is a logical storage area that contains one or more chunks that store only BLOB and CLOB data. For information about how to define *sbspaces*, see your *Informix® Performance Guide*.

When you define a BLOB or CLOB column, you can determine the following large-object characteristics:

- LOG and NOLOG: whether the database server should log the smart large object in accordance with the current database logging mode.
- KEEP ACCESS TIME and NO KEEP ACCESS TIME: whether the database server should keep track of the last time the smart large object was accessed.
- HIGH INTEG and MODERATE INTEG: whether the database server should use *sbspace* page headers and page footers to detect data corruption (HIGH INTEG), or only use page headers (MODERATE INTEG).

Use of these characteristics can affect performance. For information, see your *Informix® Performance Guide*.

When an SQL statement accesses a smart-large-object, the database server does not send the actual BLOB or CLOB data. Instead, it establishes a pointer to the data and returns this pointer. The client application can then use this pointer in open, read, or write operations on the smart large object.

To access a BLOB or CLOB column from within a client application, use one of the following application programming interfaces (APIs):

- From within Informix® ESQL/C programs, use the smart-large-object API. (For more information, see the *Informix® ESQL/C Programmer's Manual*.)
- From within a DataBlade® module, use the Client and Server API. (For more information, see the *Informix® DataBlade® API Programmer's Guide*.)

For information about smart large objects, see the *Informix® Guide to SQL: Syntax* and *Informix® Database Design and Implementation Guide*.

## Time Data Types

DATE and DATETIME data values represent zero-dimensional points in time; INTERVAL data values represent 1-dimensional spans of time, with positive or negative values. DATE precision is always an integer count of days, but various field qualifiers can define the DATETIME and INTERVAL precision. You can use DATE, DATETIME, and INTERVAL data in arithmetic and

relational expressions. You can manipulate a DATETIME value with another DATETIME value, an INTERVAL value, the current time (specified by the keyword CURRENT), or some unit of time (using the keyword UNITS).

You can use a DATE value in most contexts where a DATETIME value is valid, and vice versa. You also can use an INTERVAL operand in arithmetic operations where a DATETIME value is valid. In addition, you can add two INTERVAL values and multiply or divide an INTERVAL value by a number.

An INTERVAL column can hold a value that represents the difference between two DATETIME values or the difference between (or sum of) two INTERVAL values. In either case, the result is a span of time, which is an INTERVAL value. Conversely, if you add or subtract an INTERVAL from a DATETIME value, another DATETIME value is produced, because the result is a specific time.

[Table 77: Arithmetic Operations on DATE, DATETIME, and INTERVAL Values on page 1662](#) lists the binary arithmetic operations that you can perform on DATE, DATETIME, and INTERVAL operands, and the data type that is returned by the arithmetic expression.

**Table 77. Arithmetic Operations on DATE, DATETIME, and INTERVAL Values**

| Operand 1 | Operator | Operand 2 | Result   |
|-----------|----------|-----------|----------|
| DATE      | -        | DATETIME  | INTERVAL |
| DATETIME  | -        | DATE      | INTERVAL |
| DATE      | + or -   | INTERVAL  | DATETIME |
| DATETIME  | -        | DATETIME  | INTERVAL |
| DATETIME  | + or -   | INTERVAL  | DATETIME |
| INTERVAL  | +        | DATETIME  | DATETIME |
| INTERVAL  | + or -   | INTERVAL  | INTERVAL |
| DATETIME  | -        | CURRENT   | INTERVAL |
| CURRENT   | -        | DATETIME  | INTERVAL |
| INTERVAL  | +        | CURRENT   | DATETIME |
| CURRENT   | + or -   | INTERVAL  | DATETIME |
| DATETIME  | + or -   | UNITS     | DATETIME |
| INTERVAL  | + or -   | UNITS     | INTERVAL |
| INTERVAL  | * or /   | NUMBER    | INTERVAL |

No other combinations are allowed. You cannot add two DATETIME values because this operation does not produce either a specific time or a span of time. For example, you cannot add December 25 and January 1, but you can subtract one from the other to find the time span between them.

## Manipulating DATETIME Values

You can subtract most DATETIME values from each other.

Dates can be in any order and the result is either a positive or a negative INTERVAL value. The first DATETIME value determines the precision of the result, which includes the same time units as the first operand.

If the second DATETIME value has fewer fields than the first, the precision of the second operand is increased automatically to match the first.

In the following example, subtracting the DATETIME YEAR TO HOUR value from the DATETIME YEAR TO MINUTE value results in a positive interval value of 60 days, 1 hour, and 30 minutes. Because minutes were not included in the second operand, the database server sets the minutes value for the second operand to 0 before performing the subtraction.

```
DATETIME (2003-9-30 12:30) YEAR TO MINUTE
- DATETIME (2003-8-1 11) YEAR TO HOUR

Result: INTERVAL (60 01:30) DAY TO MINUTE
```

If the second DATETIME operand has more fields than the first (regardless of whether the precision of the extra fields is larger or smaller than those in the first operand), the additional time unit fields in the second value are ignored in the calculation.

In the next expression (and its result), the year is not included for the second operand. Therefore, the year is set automatically to the current year (from the system clock-calendar), in this example 2005, and the resulting INTERVAL is negative, which indicates that the second date is later than the first.

```
DATETIME (2005-9-30) YEAR TO DAY
- DATETIME (10-1) MONTH TO DAY

Result: INTERVAL (-1) DAY TO DAY [assuming that the current
                                year is 2005]
```

You can compare two DATETIME values by using the `mi_datetime_compare()` function.

## Manipulating DATETIME with INTERVAL Values

INTERVAL values can be added to or subtracted from DATETIME values. In either case, the result is a DATETIME value. If you are adding an INTERVAL value to a DATETIME value, the order of values is unimportant; however, if you are subtracting, the DATETIME value must come first. Adding or subtracting a positive INTERVAL value moves the DATETIME result forward or backward in time. The expression shown in the following example moves the date ahead by three years and five months:

```
DATETIME (2000-8-1) YEAR TO DAY
+ INTERVAL (3-5) YEAR TO MONTH

Result: DATETIME (2004-01-01) YEAR TO DAY
```

**Important:** Evaluate the logic of your addition or subtraction. Remember that months can have 28, 29, 30, or 31 days and that years can have 365 or 366 days.

In most situations, the database server automatically adjusts the calculation when the operands do not have the same precision. In certain contexts, however, you must explicitly adjust the precision of one value to perform the calculation. If the INTERVAL value you are adding or subtracting has fields that are not included in the DATETIME value, you must use the EXTEND function to increase the precision of the DATETIME value. (For more information about the EXTEND function, see the Expression segment in the *Informix® Guide to SQL: Syntax*.)

For example, you cannot subtract an INTERVAL MINUTE TO MINUTE value from the DATETIME value in the previous example that has a YEAR TO DAY field qualifier. You can, however, use the EXTEND function to perform this calculation, as the following example shows:

```
EXTEND (DATETIME (2008-8-1) YEAR TO DAY, YEAR TO MINUTE)
- INTERVAL (720) MINUTE(3) TO MINUTE

Result: DATETIME (2008-07-31 12:00) YEAR TO MINUTE
```

The EXTEND function allows you to explicitly increase the DATETIME precision from YEAR TO DAY to YEAR TO MINUTE. This allows the database server to perform the calculation, with the resulting extended precision of YEAR TO MINUTE.

## Manipulating DATE with DATETIME and INTERVAL Values

You can use DATE operands in some arithmetic expressions with DATETIME or INTERVAL operands by writing expressions to do the manipulating, as [Table 78: Results of Expressions That Manipulate DATE with DATETIME or INTERVAL Values on page 1664](#) shows.

**Table 78. Results of Expressions That Manipulate DATE with DATETIME or INTERVAL Values**

| Expression           | Result   |
|----------------------|----------|
| DATE - DATETIME      | INTERVAL |
| DATETIME - DATE      | INTERVAL |
| DATE + or - INTERVAL | DATETIME |

In the cases that [Table 78: Results of Expressions That Manipulate DATE with DATETIME or INTERVAL Values on page 1664](#) shows, DATE values are first converted to their corresponding DATETIME equivalents, and then the expression is evaluated by the rules of arithmetic.

Although you can interchange DATE and DATETIME values in many situations, you must indicate whether a value is a DATE or a DATETIME data type. A DATE value can come from the following sources:

- A column or program variable of type DATE
- The TODAY keyword
- The DATE() function

- The MDY function
- A DATE literal

A DATETIME value can come from the following sources:

- A column or program variable of type DATETIME
- The CURRENT keyword
- The EXTEND function
- A DATETIME literal

The database locale defines the default DATE and DATETIME formats. For the default locale, U.S. English, these formats are 'mm/dd/yy' for DATE values and 'yyyy-mm-dd hh:MM:ss' for DATETIME values.

To represent DATE and DATETIME values as character strings, the fields in the strings must be in the required order. In other words, when a DATE value is expected, the string must be in DATE format and when a DATETIME value is expected, the string must be in DATETIME format. For example, you can use the string `10/30/2008` as a DATE string but not as a DATETIME string. Instead, you must use `2008-10-30` or `08-10-30` as the DATETIME string.

In a nondefault locale, literal DATE and DATETIME strings must match the formats that the locale defines. For more information, see the *Informix® GLS User's Guide*.

You can customize the DATE format that the database server expects with the **DBDATE** and **GL\_DATE** environment variables. You can customize the DATETIME format that the database server expects with the **DBTIME** and **GL\_DATETIME** environment variables. For more information, see [DBDATE environment variable on page 1707](#) and [GL\\_DATE environment variable on page 1707](#). For more information about all these environment variables, see the *Informix® GLS User's Guide*.

You can also subtract one DATE value from another DATE value, but the result is a positive or negative INTEGER count of days, rather than an INTERVAL value. If an INTERVAL value is required, you can either use the UNITS DAY operator to convert the INTEGER value into an INTERVAL DAY TO DAY value, or else use EXTEND to convert one of the DATE values into a DATETIME value before subtracting.

For example, the following expression uses the **DATE()** function to convert character string constants to DATE values, calculates their difference, and then uses the UNITS DAY keywords to convert the INTEGER result into an INTERVAL value:

```
(DATE ('5/2/2007') - DATE ('4/6/1968')) UNITS DAY
```

```
Result: INTERVAL (12810) DAY(5) TO DAY
```

**Important:** Because of the high precedence of UNITS relative to other SQL operators, you should generally enclose any arithmetic expression that is the operand of UNITS within parentheses, as in the preceding example.

If you need YEAR TO MONTH precision, you can use the EXTEND function on the first DATE operand, as the following example shows:

```
EXTEND (DATE ('5/2/2007'), YEAR TO MONTH) - DATE ('4/6/1969')
```

```
Result: INTERVAL (39-01) YEAR TO MONTH
```

The resulting INTERVAL precision is YEAR TO MONTH, because the DATETIME value came first. If the DATE value had come first, the resulting INTERVAL precision would have been DAY(5) TO DAY.

---

## Manipulating INTERVAL Values

You can add or subtract INTERVAL values only if both values are from the same class; that is, if both are year-month or both are day-time.

In the following example, a SECOND TO FRACTION value is subtracted from a MINUTE TO FRACTION value:

```
INTERVAL (100:30.0005) MINUTE(3) TO FRACTION(4)
- INTERVAL (120.01) SECOND(3) TO FRACTION
Result: INTERVAL (98:29.9905) MINUTE TO FRACTION(4)
```

The use of numeric qualifiers alerts the database server that the MINUTE and FRACTION in the first value and the SECOND in the second value exceed the default number of digits.

When you add or subtract INTERVAL values, the second value cannot have a field with greater precision than the first. The second INTERVAL, however, can have a field of smaller precision than the first. For example, the second INTERVAL can be HOUR TO SECOND when the first is DAY TO HOUR. The additional fields (in this case MINUTE and SECOND) in the second INTERVAL value are ignored in the calculation.

You can compare two INTERVAL values by using the `mi_interval_compare()` function.

---

## Multiplying or Dividing INTERVAL Values

You can multiply or divide INTERVAL values by numbers. Any remainder from the calculation is ignored, however, and the result is truncated to the precision of the INTERVAL. The following expression multiplies an INTERVAL value by a literal number that has a fractional part:

```
INTERVAL (15:30.0002) MINUTE TO FRACTION(4) * 2.5
Result: INTERVAL (38:45.0005) MINUTE TO FRACTION(4)
```

In this example,  $15 * 2.5 = 37.5$  minutes,  $30 * 2.5 = 75$  seconds, and  $2 * 2.5 = 5$  FRACTION (4). The 0.5 minute is converted into 30 seconds and 60 seconds are converted into 1 minute, which produces the final result of 38 minutes, 45 seconds, and 0.0005 of a second. The result of any calculation has the same precision as the original INTERVAL operand.

## Extended Data Types

HCL Informix® enables you to create *extended data types* to characterize data that cannot easily be represented with the built-in data types. (You cannot, however, use extended data types in distributed transactions that query external tables.) You can create these categories of extended data types:

- Complex data types
- Distinct data types
- Opaque data types

Sections that follow provide an overview of each of these data types.

For more information about extended data types, see the *Informix® Database Design and Implementation Guide* and *Informix® User-Defined Routines and Data Types Developer's Guide*.

#### Related reference

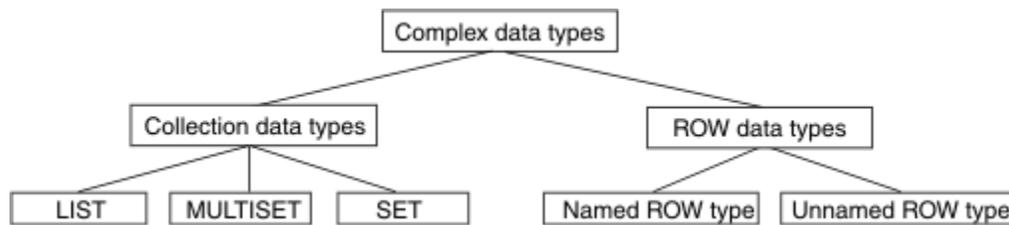

[Summary of data types on page 1626](#)

## Complex data types

A *complex data type* can store one or more values of other built-in or extended data types.

[Figure 18: Complex Data Types of HCL Informix on page 1667](#) shows the complex types that HCL Informix® supports.

Figure 18. Complex Data Types of HCL Informix®

The following table summarizes the structure of the complex data types.

**Table 79. Collection types are complex data types that are made up of elements, each of which is of the same data type.**

| Collection types | Description  |
|------------------|--|
| LIST             | A group of ordered elements, each of which need not be unique within the group.              |
| MULTISET         | A group of elements, each of which need not be unique. The order of the elements is ignored. |
| SET              | A group of elements, each of which is unique. The order of the elements is ignored.          |

**Table 80. ROW types are complex data types that are made up of fields.**

| ROW types        | Description                                       |
|------------------|---|
| Named ROW type   | Row types that are identified by their name.      |
| Unnamed ROW type | Row types that are identified by their structure. |

Complex data types can be nested. For example, you can construct a ROW type whose fields include one or more sets, multisets, ROW types, and lists. Likewise, a collection type can have elements whose data type is a ROW type or a collection type.

Complex types that include opaque types inherit the following support functions.

- **input**
- **output**
- **send**
- **recv**
- **import**
- **export**
- **import\_binary**
- **export\_binary**
- **assign**
- **destroy**
- **LO\_handles**
- **hash**
- **lessthan**
- **equal**
- **lessthan** (for ROW types only)

The topics that follow summarize the complex data types. For more information, see the *Informix® Database Design and Implementation Guide*.

## Collection Data Types

A collection data type is a complex type that is made up of one or more elements, all of the same data type. A collection element can be of any data type (including other complex types) except BYTE, TEXT, SERIAL, SERIAL8, or BIGSERIAL.

**Important:** An element cannot have a *NULL* value. You must specify the *NOT NULL* constraint for collection elements. No other constraints are valid for collections.

HCL Informix® supports three kinds of built-in collection types: LIST, SET, and MULTISSET. The keywords used to declare these collections are the names of the *type constructors* or just *constructors*. For the syntax of collection types, see the *Informix® Guide to SQL: Syntax*. No more than 97 columns of the same table can be declared as collection data types.

When you specify element values for a collection, list the element values after the constructor and between braces ( `{ }` ). For example, suppose you have a collection column with the following MULTISSET data type:

```
CREATE TABLE table1
(
  mset_col MULTISSET(INTEGER NOT NULL)
)
```

The next INSERT statement adds one group of element values to this column. (The word MULTiset in these two examples is the MULTiset constructor.)

```
INSERT INTO table1 VALUES (MULTiset{5, 9, 7, 5})
```

You can leave the braces empty to indicate an empty set:

```
INSERT INTO table1 VALUE (MULTiset{})
```

An empty collection is not equivalent to a NULL value for the column.

## Accessing collection data

### About this task

To access the elements of a collection column, you must fetch the collection into a collection variable and modify the contents of the collection variable. Collection variables can be either of the following types:

- Variables in an SPL routine

For more information, see the *Informix® Guide to SQL: Tutorial*.

- Host variables in Informix® ESQL/C programs

For more information, see the *Informix® ESQL/C Programmer's Manual*.

You can also use nested dot notation to access collection data. For more about accessing elements of a collection, see the *Informix® Guide to SQL: Tutorial*.

**Important:** Collection data types are not valid as arguments to functions that are used for functional indexes.

## ROW Data Types

A ROW data type is an ordered collection of one or more elements, called *fields*. Each field has a name and a data type. The fields of a ROW are comparable to the columns of a table, but with important differences:

- A field has no default clause.
- You cannot define constraints on a field.
- You can only use fields with row types, not with tables.

Two kinds of ROW data types exist:

- *Named ROW data types* are identified by their names.
- *Unnamed ROW data types* are identified by their structure.

The *structure* of an unnamed ROW data type is the number (and the order of data types) of its fields.

No more than 195 columns of the same table can be declared as ROW data types. For more information about ROW data types, see [ROW data type, Named on page 1646](#) and [ROW data type, Unnamed on page 1648](#).

You can cast between named and unnamed ROW data types; this is described in the *Informix® Database Design and Implementation Guide*.

## Distinct Data Types

A distinct data type has the same internal structure as some other source data type in the database. The source type can be a built-in or extended data type. What distinguishes a distinct type from its source type are support functions that are defined on the distinct type.

No more than approximately 97 columns of the same table can be DISTINCT of collection data types (SET, LIST, and MULTISSET). No more than approximately 195 columns of the same table can be DISTINCT types that are based on BYTE, TEXT, ROW, LVARCHAR, NVARCHAR, or VARCHAR source types. (Here 195 columns is an approximate lower limit that applies to platforms with a 2 Kb base page size. For platforms with a base page size of 4 Kb, such as Windows™ and AIX® systems, the upper limit is approximately 450 columns of these data types.) For more information, see the section [DISTINCT data types on page 1638](#). See also *Informix® User-Defined Routines and Data Types Developer's Guide*.

## Opaque Data Types

An opaque data type is a user-defined or built-in data type that is fully encapsulated. The internal structure of an opaque data type is unknown to the database server.

Except for user-defined types (UDTs) that are DISTINCT of built-in non-opaque types, UDTs whose source types are built-in types are opaque data types. Similarly, UDTs that are DISTINCT of built-in opaque types are opaque types.

### Built-in opaque data types

The built-in data types BLOB, BOOLEAN, CLOB, BSON, JSON, and LVARCHAR are implemented as opaque data types. You can access all of these in other databases of the same Informix® instance, but you cannot access the BLOB or CLOB built-in opaque data types in cross-server distributed operations.

UDTs that are DISTINCT of built-in opaque types and that are cast to built-in types are valid in cross-server queries and other DML operations, but all the casts and all the DISTINCT OF definitions for the UDTs must be identical in every participating database.

Several system catalog tables, whose schema are shown in [Structure of the System Catalog on page 1555](#), have columns of built-in opaque data types. For information on how the system catalog encodes columns of built-in opaque data types, see [SYSCOLUMNS on page 1568](#).

### User-defined opaque data types

You must provide the following information to the database server for an opaque data type:

- A data structure for how the data values are stored on disk
- Support functions to determine how to convert between the disk storage format and the user format for data entry and display
- Secondary access methods that determine how the index on this data type is built, used, and manipulated
- User functions that use the data type
- A system catalog entry to register the opaque type in the database

The internal structure of an opaque type is not visible to the database server and can only be accessed through user-defined routines. Definitions for opaque types are stored in the `sysxdtypes` system catalog table. These SQL statements maintain the definitions of opaque types in the database:

- The `CREATE OPAQUE TYPE` statement registers a new opaque type in the database.
- The `DROP TYPE` statement removes a previously defined opaque type from the database.

For more information, see the section [OPAQUE data types on page 1646](#). See also *Informix® User-Defined Routines and Data Types Developer's Guide*.

## Data Type Casting and Conversion

### About this task

Occasionally, the data type that was assigned to a column with the `CREATE TABLE` statement is inappropriate. You can change the data type of a column when you are required to store larger values than the current data type can accommodate. The database server allows you to change the data type of the column or to cast its values to a different data type with either of the following methods:

- Use the `ALTER TABLE` statement to modify the data type of a column.

For example, if you create a `SMALLINT` column and later find that you must store integers larger than 32,767, you must change the data type of that column to store the larger value. You can use `ALTER TABLE` to change the data type to `INTEGER`. The conversion changes the data type of all values that currently exist in the column and any new values that might be added.

- Use the `CAST AS` keywords or the double colon (`::`) cast operator to cast a value to a different data type.

Casting does not permanently alter the data type of a value; it expresses the value in a more convenient form. Casting user-defined data types into built-in types allows client programs to manipulate data types without knowledge of their internal structure.

If you change data types, the new data type must be able to store all of the old value.

Both data-type conversion and casting depend on casts registered in the `syscasts` system catalog table. For information about `syscasts`, see [SYSCASTS on page 1565](#).

A cast is either built-in or user defined. Guidelines exist for casting distinct and extended data types. For more information about casting opaque data types, see *Informix® User-Defined Routines and Data Types Developer's Guide*. For information about casting other extended data types see, the *Informix® Database Design and Implementation Guide*.

## Using Built-in Casts

User **informix** owns built-in casts. They govern conversions from one built-in data type to another. Built-in casts allow the database server to attempt the following data-type conversions:

- A character type to any other character type
- A character type to or from another built-in type
- A numeric type to any other numeric type

The database server automatically invokes appropriate built-in casts when required. For time data types, conversion between DATE and DATETIME data types requires explicit casts with the EXTEND function, and explicit casts with the UNITS operator are required for number-to-INTERVAL conversion. Built-in casts are unavailable for converting large (BYTE, BLOB, CLOB, and TEXT) built-in types to other built-in data types.

When you convert a column from one built-in data type to another, the database server applies the appropriate built-in casts to each value already in the column. If the new data type cannot store any of the resulting values, the ALTER TABLE statement fails.

For example, if you try to convert a column from the INTEGER data type to the SMALLINT data type and the following values exist in the INTEGER column, the database server does not change the data type, because SMALLINT columns cannot accommodate numbers greater than 32,767:

```
100    400    700    50000    700
```

The same situation might occur if you attempt to transfer data from FLOAT or SMALLFLOAT columns to INTEGER, SMALLINT, or DECIMAL columns. Errors of overflow, underflow, or truncation can occur during data type conversion.

Sections that follow describe database server behavior during certain types of casts and conversions.

## Converting from number to number

When you convert data from one number data type to another, you occasionally find rounding errors.

The following table indicates which numeric data type conversions are acceptable and what kinds of errors you can encounter when you convert between certain numeric data types. In the table, the following codes are used:

### OK

No error

### P

An error can occur, depending on the precision of the decimal

**E**

An error can occur, depending on the data value

**D**

No error, but less significant digits might be lost

**Table 81. Acceptable conversions and possible errors**

| Target Type | SMALL INT | INTEGER | INT8 | SMALL<br>FLOAT | FLOAT | DECIMAL |
|-------------|-----------|---------|------|----------------|-------|---------|
| SMALLINT    | OK        | OK      | OK   | OK             | OK    | OK      |
| INTEGER     | E         | OK      | OK   | E              | OK    | P       |
| INT8        | E         | E       | OK   | D              | E     | P       |
| SMALLFLOAT  | E         | E       | E    | OK             | OK    | P       |
| FLOAT       | E         | E       | E    | D              | OK    | P       |
| DECIMAL     | E         | E       | E    | D              | D     | P       |

For example, if you convert a FLOAT value to DECIMAL(4,2), your database server rounds off the floating-point number before storing it as DECIMAL.

This conversion can result in an error depending on the precision assigned to the DECIMAL column.

## Converting Between Number and Character

You can convert a character column (of a data type such as CHAR, NCHAR, NVARCHAR, or VARCHAR) to a numeric column. If a data string, however, contains any characters that are not valid in a number column (for example, the letter *l* instead of the number *1*), the database server returns an error.

You can also convert a numeric column to a character column. If the character column is not large enough to receive the number, however, the database server generates an error. If the database server generates an error, it cannot complete the ALTER TABLE statement or cast, and leaves the column values as characters. You receive an error message and the statement is rolled back automatically (regardless of whether you are in a transaction).

## Converting Between INTEGER and DATE

You can convert an integer column (SMALLINT, INTEGER, or INT8) to a DATE value. The database server interprets the integer as a value in the internal format of the DATE column. You can also convert a DATE column to an integer column. The database server stores the internal format of the DATE column as an integer representing a Julian date.

## Converting Between DATE and DATETIME

You can convert DATE columns to DATETIME columns. If the DATETIME column contains more fields than the DATE column, however, the database server either ignores the fields or fills them with zeros. The illustrations in the following list show how these two data types are converted (assuming that the default date format is *mm/dd/yyyy*):

- If you convert DATE to DATETIME YEAR TO DAY, the database server converts the existing DATE values to DATETIME values. For example, the value 08/15/2002 becomes 2002-08-15.
- If you convert DATETIME YEAR TO DAY to the DATE format, the value 2002-08-15 becomes 08/15/2002.
- If you convert DATE to DATETIME YEAR TO SECOND, the database server converts existing DATE values to DATETIME values and fills in the additional DATETIME fields with zeros. For example, 08/15/2002 becomes 2002-08-15 00:00:00.
- If you convert DATETIME YEAR TO SECOND to DATE, the database server converts existing DATETIME to DATE values but drops fields for time units smaller than DAY. For example, 2002-08-15 12:15:37 becomes 08/15/2002.

## Using User-Defined Casts

Implicit and explicit casts are owned by the users who create them. They govern casts and conversions between user-defined data types and other data types. Developers of user-defined data types must create certain implicit and explicit casts and the functions that are used to implement them. The casts allow user-defined types to be expressed in a form that clients can manipulate.

For information about how to register and use implicit and explicit casts, see the CREATE CAST statement in the *Informix® Guide to SQL: Syntax* and the *Informix® Database Design and Implementation Guide*.

## Implicit Casts

Implicit casts allow you to convert a user-defined data type to a built-in type or vice versa. The database server automatically invokes a single implicit cast when it must evaluate and compare expressions or pass arguments. Operations that require more than one implicit cast fail.

Users can explicitly invoke an implicit cast using the CAST AS keywords or the double colon (::) cast operator.

## Explicit Casts

Explicit casts, unlike implicit casts or built-in casts, are *never* invoked automatically by the database server. Users must invoke them explicitly with the CAST AS keywords or with the double colon (::) cast operator.

## Determining Which Cast to Apply

The database server uses the following rules to determine which cast to apply in a particular situation:

- To compare two built-in types, the database server automatically invokes the appropriate built-in casts.
- The database server applies only one implicit cast per operand. If two or more casts are required to convert the operand to the specified type, the user must explicitly invoke the additional casts.

In the following example, the literal value 5.55 is implicitly cast to DECIMAL, and is then explicitly cast to MONEY, and finally to yen:

```
CREATE DISTINCT TYPE yen AS MONEY
. . .
INSERT INTO currency_tab
VALUES (5.55::MONEY::yen)
```

- To compare a distinct type to its source type, the user must explicitly cast one type to the other.
- To compare a distinct type to a type other than its source, the database server looks for an implicit cast between the source type and the specified type.

If neither cast is registered, the user must invoke an explicit cast between the distinct type and the specified type.

If this cast is not registered, the database server automatically invokes a cast from the source type to the specified type.

If none of these casts is defined, the comparison fails.

- To compare an opaque type to a built-in type, the user must explicitly cast the opaque type to a data type that the database server understands (such as LVARCHAR, SENDRECV, IMPEXP, or IMPEXPBIN). The database server then invokes built-in casts to convert the results to the specified built-in type.
- To compare two opaque types, the user must explicitly cast one opaque type to a form that the database server understands (such as LVARCHAR, SENDRECV, IMPEXP, or IMPEXPBIN) and then explicitly cast this type to the second opaque type.

For information about casting and the BOOLEAN, BSON, JSON, IMPEXP, IMPEXPBIN, LVARCHAR, and SENDRECV built-in opaque data types, see *Informix® User-Defined Routines and Data Types Developer's Guide*.

## Casts for distinct types

You define a distinct type based on a built-in type or an existing opaque type or ROW type. Although data of the distinct type has the same length and alignment and is passed in the same way as data of the source type, the two cannot be compared directly. To compare a distinct type and its source type, you must explicitly cast one type to the other.

When you create a new distinct type, the database server automatically registers two explicit casts:

- A cast from the distinct type to its source type
- A cast from the source type to the distinct type

You can create an implicit cast between a distinct type and its source type. To create an implicit cast, however, you must first drop the default explicit cast between the distinct type and its source type.

You also can use all casts that have been registered for the source type without modification on the distinct type. You can also create and register new casts and support functions that apply only to the distinct type.

For examples that show how to create a cast function for a distinct type and register the function as cast, see the *Informix® Database Design and Implementation Guide*.

**Important:** For releases of HCL Informix® earlier than Version 9.21, distinct data types inherited the built-in casts that are provided for the source type. The built-in casts of the source type are not inherited by distinct data types in this release.

## What Extended Data Types Can Be Cast?

The next table shows the extended data type combinations that you can cast.

**Table 82. Extended data type combinations**

| Target Type             | Opaque Type                       | Distinct Type        | Named ROW Type        | Unnamed ROW Type      | Collection Type       | Built-in Type                     |
|-------------------------|-----------------------------------|----------------------|-----------------------|-----------------------|-----------------------|-----------------------------------|
| <b>Opaque Type</b>      | Explicit or implicit              | Explicit             | Explicit              | Not Valid             | Not Valid             | Explicit or implicit <sup>3</sup> |
| <b>Distinct Type</b>    | Explicit <sup>3</sup>             | Explicit             | Explicit              | Not Valid             | Not Valid             | Explicit or implicit              |
| <b>Named ROW Type</b>   | Explicit <sup>3</sup>             | Explicit             | Explicit <sup>3</sup> | Explicit <sup>1</sup> | Not Valid             | Not Valid                         |
| <b>Unnamed ROW Type</b> | Not Valid                         | Not Valid            | Explicit <sup>1</sup> | Implicit <sup>1</sup> | Not Valid             | Not Valid                         |
| <b>Collection Type</b>  | Not Valid                         | Not Valid            | Not Valid             | Not Valid             | Explicit <sup>2</sup> | Not Valid                         |
| <b>Built-in Type</b>    | Explicit or implicit <sup>3</sup> | Explicit or implicit | Not Valid             | Not Valid             | Not Valid             | System defined (implicit)         |

<sup>1</sup> Applies when two ROW types are structurally equivalent or casts exist to handle data conversions where corresponding field types are not the same.

<sup>2</sup> Applies when a cast exists to convert between the element types of the respective collection types.

<sup>3</sup> Applies when a user-defined cast exists to convert between the two data types.

The table shows only whether a cast between a source type and a target type are possible. In some cases, you must first create a user-defined cast before you can perform a conversion between two data types. In other cases, the database server provides either an implicit cast or a built-in cast that you must explicitly invoke.

## Operator Precedence

An *operator* is a symbol or keyword that can be in an SQL expression. Most SQL operators are restricted in the data types of their operands and returned values. Some operators only support operands of built-in data types; others can support built-in and extended data types as operands.

The following table shows the precedence of the operators that HCL Informix® supports, in descending (highest to lowest) order of precedence. Operators with the same precedence are listed in the same row.

| Operator Precedence                             | Example in Expression  |
|---|--|
| . ( <i>membership</i> ) [] ( <i>substring</i> ) | <b>customer.phone</b> [1, 3]                                     |
| UNITS   | <b>x</b> UNITS DAY   |
| + - ( <i>unary</i> )                            | <b>- y</b>   |
| :: ( <i>cast</i> )                              | NULL::TEXT   |
| * /   | <b>x / y</b>   |
| + - ( <i>binary</i> )                           | <b>x -y</b>  |
| ( <i>concatenation</i> )                        | <b>customer.fname    customer.lname</b>                          |
| ANY ALL SOME                                    | <b>orders.ship_date &gt; SOME (SELECT paid_date FROM orders)</b> |
| NOT   | NOT <b>y</b>   |
| < <= = > >= != <>                               | <b>x &gt;= y</b>   |
| IN BETWEEN ... AND LIKE MATCHES                 | <b>customer.fname MATCHES y</b>                                  |
| AND   | <b>x AND y</b>   |
| OR  | <b>x OR y</b>  |

See the *Informix® Guide to SQL: Syntax* for the syntax and semantics of these SQL operators.

## Environment variables

Various *environment variables* affect the functionality of your HCL Informix® products. You can set environment variables that identify your terminal, specify the location of your software and define other parameters.

Some environment variables are required; others are optional. You must either set or accept the default setting for required environment variables.

These topics describe how to use the environment variables that apply to one or more HCL Informix® products and shows how to set them.

## Types of environment variables

Two types of environment variables are explained in this chapter:

- Environment variables that are specific to HCL Informix®  
Set HCL Informix® environment variables when you want to work with HCL Informix® products. Each HCL Informix® product publication specifies the environment variables that you must set to use that product.
- Environment variables that are used with a specific operating system  
HCL Informix® products rely on the correct setting of certain standard operating system environment variables. For example, you must always set the **PATH** environment variable.

In a UNIX™ environment, you might also be required to set the TERMCAP or TERMINFO environment variable to use some products effectively.

The GLS environment variables that support nondefault locales are described in the *Informix® GLS User's Guide*. The GLS variables are included in the list of environment variables in [Table 83: Uses for environment variables on page 1687](#).

The database server uses the environment variables that were in effect at the time when the database server was initialized.

The `onstat -g env` command lists the active environment settings.

**Tip:** Additional environment variables that are specific to your client application or SQL API might be explained in the publication for that product.

**Important:** Do not set any environment variable in the home directory of user **informix** (or in the file `.informix` in that directory) while initializing the database and creating the **sysmaster** database.

## Limitations on environment variables

## Size of a block of environment variables

At the start of a session, the client groups all the environment variables that the server will use and sends the environment variables to the server as single block. The maximum size of this block is 32K. If the block of environment variables is greater than 32K, the error -1832 is returned to the application. The text of this error is "Environment block is greater than 32K."

To resolve this error, you can either unset one or more environment variables or reduce the size of some of the environment variables.

## Using environment variables on UNIX™

You can set, unset, modify, and view environment variables. If you already use any HCL Informix® products, some or all of the appropriate environment variables might be set.

You can set environment variables on UNIX™ in the following places:

- At the system prompt on the command line

When you set an environment variable at the system prompt, you must reassign it the next time you log in to the system.

- In an environment-configuration file

An environment-configuration file is a common or private file where you can set all the environment variables that HCL Informix® products use. The use of such files reduces the number of environment variables that you must set at the command line or in a shell file.

- In a login file

Values of environment variables set in your `.login`, `.cshrc`, or `.profile` file are assigned automatically every time you log in to the system.

- In the SET ENVIRONMENT statement of SQL

Values of some environment variables can reset by the SET ENVIRONMENT statement. The scope of the new settings is generally the routine that executed the SET ENVIRONMENT statement, but it is the current session for the **OPTCOMPIND** environment variable of Informix®, as described in the section [OPTCOMPIND environment variable on page 1743](#). For more information about these routines and on the SET ENVIRONMENT statement, see the *Informix® Guide to SQL: Syntax*.

In Informix® ESQL/C, you can set supported environment variables within an application with the `putenv()` system call and retrieve values with the `getenv()` system call, if your UNIX™ system supports these functions. For more information about `putenv()` and `getenv()`, see the *Informix® ESQL/C Programmer's Manual* and your C documentation.

## Setting environment variables in a configuration file

### About this task

The common (shared) environment-configuration file that is provided with HCL Informix® products is located in **\$INFORMIXDIR/etc/informix.rc**. Permissions for this shared file must be set to [644](#).

A user can override the system or shared environment variables by setting variables in a private environment-configuration file. This file must have all of the following characteristics:

- Stored in the user's home directory
- Named **.informix**
- Permissions set to readable by the user

An environment-configuration file can contain comment lines (preceded by the `#` comment indicator) and variable definition lines that set values (separated by blank spaces or tabs), as the following example shows:

```
# This is an example of an environment-configuration file
#
DBDATE DMY4-
#
# These are ESQL/C environment variable settings
#
INFORMIX gcc
CPFIRST TRUE
```

You can use the **ENVIGNORE** environment variable, described in [ENVIGNORE environment variable \(UNIX\) on page 1721](#), to override one or more entries in an environment-configuration file. Use the HCL Informix® **chkenv** utility, described in [Checking environment variables with the chkenv utility on page 1682](#), to perform a validity check on the contents of an environment-configuration file. The **chkenv** utility returns an error message if the file contains a bad environment variable or if the file is too large.

The first time you set an environment variable in a shell file or environment-configuration file, you must tell the shell process to read your entry before you work with your HCL Informix® product. If you use a C shell, **source** the file; if you use a Bourne or Korn shell, use a period ( `.` ) to execute the file.

## Setting environment variables at login time

### About this task

Add commands that set your environment variables to the appropriate login file:

#### For C shell

**.login** or **.cshrc**

#### For Bourne shell or Korn shell

**.profile**

## Syntax for setting environment variables

Use standard UNIX™ commands to set environment variables. The examples in the following table show how to set the ABCD environment variable to *value* for the C shell, Bourne shell, and Korn shell. The Korn shell also supports a shortcut, as the last row indicates. Environment variables are case-sensitive.

| Shell  | Command   |
|--------|---|
| C      | <code>setenv ABCD value</code>                      |
| Bourne | <code>ABCD=value</code><br><code>export ABCD</code> |
| Korn   | <code>ABCD=value</code><br><code>export ABCD</code> |
| Korn   | <code>export ABCD=value</code>                      |

The following diagram shows how the syntax for setting an environment variable is represented throughout this chapter. These diagrams indicate the setting for the C shell; for the Bourne or Korn shells, use the syntax illustrated in the preceding table.

**setenv**ABCD*value*

## Unsetting environment variables

### About this task

To unset an environment variable, enter the following command.

| Shell          | Command                    |
|----------------|----------------------------|
| C              | <code>unsetenv ABCD</code> |
| Bourne or Korn | <code>unset ABCD</code>    |

## Modifying an environment-variable setting

### About this task

Sometimes you must add information to an environment variable that is already set. For example, the **PATH** environment variable is always set on UNIX™. When you use HCL Informix® productd, you must add to the **PATH** setting the name of the directory where the executable files for the HCL Informix® products are stored.

In the following example, the **INFORMIXDIR** is **/usr/informix**. (That is, during installation, the HCL Informix® products were installed in the **/usr/informix** directory.) The executable files are in the **bin** subdirectory, **/usr/informix/bin**. To add this directory to the front of the C shell **PATH** environment variable, use the following command:

```
setenv PATH /usr/informix/bin:$PATH
```

Rather than entering an explicit pathname, you can use the value of the **INFORMIXDIR** environment variable (represented as **\$INFORMIXDIR**), as the following example shows:

```
setenv INFORMIXDIR /usr/informix
setenv PATH $INFORMIXDIR/bin:$PATH
```

You might prefer to use this version to ensure that your **PATH** entry does not conflict with the search path that was set in **INFORMIXDIR**, and so that you are not required to reset **PATH** whenever you change **INFORMIXDIR**. If you set the **PATH** environment variable on the C shell command line, you might be required to include braces ( `{ }` ) with the existing **INFORMIXDIR** and **PATH**, as the following command shows:

```
setenv PATH ${INFORMIXDIR}/bin:${PATH}
```

For more information about how to set and modify environment variables, see the publications for your operating system.

## Viewing your environment-variable settings

### About this task

After you install one or more HCL Informix® products, enter the following command at the system prompt to view your current environment settings.

| UNIX™ version  | Command  |
|----------------|----------|
| BSD UNIX™      | env      |
| UNIX™ System V | printenv |

## Checking environment variables with the chkenv utility

### About this task

The **chkenv** utility checks the validity of shared or private environment-configuration files. It validates the names of the environment variables in the file, but not their values. Use **chkenv** to provide debugging information when you define, in an environment-configuration file, all the environment variables that your HCL Informix® products use.

**chkenv***pathname filename*

#### **filename**

is the name of the environment-configuration file to be debugged.

#### **pathname**

is the full directory path in which the environment variable file is located.

File **\$INFORMIXDIR/etc/informix.rc** is the shared environment-configuration file. A private environment-configuration file is stored as **.informix** in the home directory of the user. If you specify no *pathname* for **chkenv**, the utility checks both the shared and private environment configuration files. If you provide a *pathname*, **chkenv** checks only the specified file.

Issue the following command to check the contents of the shared environment-configuration file:

```
chkenv informix.rc
```

The **chkenv** utility returns an error message if it finds a bad environment-variable name in the file or if the file is too large. You can modify the file and rerun the utility to check the modified environment-variable names.

HCL Informix® products ignore all lines in the environment-configuration file, starting at the point of the error, if the **chkenv** utility returns the following message:

```
-33523      filename: Bad environment variable on line number.
```

If you want the product to ignore specified environment-variables in the file, you can also set the **ENVIGNORE** environment variable. For a discussion of the use and format of environment-configuration files and the **ENVIGNORE** environment variable, see page [ENVIGNORE environment variable \(UNIX\) on page 1721](#).

## Rules of precedence for environment variables

When HCL Informix® products accesses an environment variable, normally the following rules of precedence apply:

1. Of highest precedence is the value that is defined in the environment (shell) by explicitly setting the value at the shell prompt.
2. The second highest precedence goes to the value that is defined in the private environment-configuration file in the home directory of the user (`~/.informix`).
3. The next highest precedence goes to the value that is defined in the common environment-configuration file (`$INFORMIXDIR/etc/informix.rc`).
4. The lowest precedence goes to the default value, if one exists.

For precedence information about GLS environment variables, see the *Informix® GLS User's Guide*.

**Important:** If you set one or more environment variables before you start the database server, and you do not explicitly set the same environment variables for your client products, the clients will adopt the original settings.

## Using environment variables on Windows™

The following sections discuss setting, viewing, unsetting, and modifying environment variables for Windows™ applications.

### Where to set environment variables on Windows™

You can set environment variables in several places on Windows™, depending on which HCL Informix® application you use.

Environment variables can be set in several ways, as described in [Setting environment variables on Windows on page 1684](#).

The SET ENVIRONMENT statement of SQL can set certain routine-specific environment options. For more information, see the description of SET ENVIRONMENT in the *Informix® Guide to SQL: Syntax*.

To use client applications such as Informix® ESQL/C or the Schema Tools on Windows™ environment, use the Setnet32 utility to set environment variables. For information about the Setnet32 utility, see the *Informix® Client Products Installation Guide* for your operating system.

In Informix® ESQL/C, you can set supported environment variables within an application with the `ifx_putenv()` function and retrieve values with the `ifx_getenv()` function, if your Windows™ system supports them. For more information about `ifx_putenv()` and `ifx_getenv()`, see the *Informix® ESQL/C Programmer's Manual*.

## Setting environment variables on Windows™

### About this task

You can set environment variables for command-prompt utilities in the following ways:

- With the System applet in the Control Panel
- In a command-line session

## Using the system applet to change environment variables

The System applet provides a graphical interface to create, modify, and delete system-wide and user-specific variables. Environment variables that are set with the System applet are visible to all command-prompt sessions.

### About this task

#### To change environment variables with the System applet in the control panel

1. Double-click the System applet icon from the Control Panel window.
2. Click the Environment tab near the top of the window.

Two list boxes display System Environment Variables and User Environment Variables. System Environment Variables apply to an entire system, and User Environment Variables apply only to the sessions of the individual user.

3. To change the value of an existing variable, select that variable. The name of the variable and its current value are in the boxes at the bottom of the window.
4. To add a new variable, highlight an existing variable and type the new variable name in the box at the bottom of the window.
5. Next, enter the value for the new variable at the bottom of the window and click **Set**.
6. To delete a variable, select the variable and click **Delete**.

### Results

**Important:** In order to use the System applet to change System environment variables, you must belong to the Administrators group. For information about assigning users to groups, see your operating-system documentation.

## Using the command prompt to change environment variables

You can change the setting of an environment variable at a command prompt.

### About this task

The following diagram shows the syntax for setting an environment variable at a command prompt in Windows™.

**set***ABCD=value*

If no *value* is specified, the environment variable is unset, as if it did not exist.

To view your current settings after one or more HCL Informix® products are installed, enter the following command at the command prompt.

**set**

Sometimes you must add information to an environment variable that is already set. For example, the **PATH** environment variable is always set in Windows™ environments. When you use HCL Informix® products, you must add the name of the directory where the executable files for the HCL Informix® products are stored to the **PATH**.

In the following example, **INFORMIXDIR** is `d:\informix` (that is, during installation, HCL Informix® products were installed in the `d:\informix` directory). The executable files are in the `bin` subdirectory, `d:\informix\bin`. To add this directory at the beginning of the **PATH** environment-variable value, use the following command:

```
set PATH=d:\informix\bin;%PATH%
```

Rather than entering an explicit pathname, you can use the value of the **INFORMIXDIR** environment variable (represented as **%INFORMIXDIR%**), as the following example shows:

```
set INFORMIXDIR=d:\informix
set PATH=%PATH%
```

You might prefer to use this version to ensure that your **PATH** entry does not contradict the search path that was set in **INFORMIXDIR** and to avoid the requirement to reset **PATH** whenever you change **INFORMIXDIR**.

For more information about setting and modifying environment variables, see your operating-system publications.

## Using dbservername.cmd to initialize a command-prompt environment

Each time that you open a Windows™ command prompt, it acts as an independent environment. Therefore, environment variables that you set within it are valid only for that particular command-prompt instance.

### About this task

For example, if you open one command window and set the variable, **INFORMIXDIR**, and then open another command window and type `set` to check your environment, you will find that **INFORMIXDIR** is not set in the new command-prompt session.

The database server installation program creates a batch file that you can use to configure command-prompt utilities, ensuring that your command-prompt environment is initialized correctly each time that you run a command-prompt session. The batch file, `dbservername.cmd`, is located in **%INFORMIXDIR%**, and is a plain text file that you can modify with any text

editor. If you have more than one database server installed in %INFORMIXDIR%, there will be more than one batch file with the .cmd extension, each bearing the name of the database server with which it is associated.

To run dbservername.cmd from a command prompt, type dbservername or configure a command prompt so that it runs dbservername.cmd automatically at start.

## Rules of precedence for Windows™ environment variables

When HCL Informix® products access an environment variable, normally the following rules of precedence apply:

1. The setting in Setnet32 with the **Use my settings** box selected.
2. The setting in Setnet32 with the **Use my settings** box cleared.
3. The setting on the command line before running the application.
4. The setting in Windows™ as a user variable.
5. The setting in Windows™ as a system variable.
6. The lowest precedence goes to the default value.

An application examines the first five values as it starts. Unless otherwise stated, changing an environment variable after the application is running does not have any effect.

## Environment variables in Informix® products

The topics that follow discuss (in alphabetic order) environment variables that HCL Informix® database server products and their utilities use.

**Important:** The descriptions of the following environment variables include the syntax for setting the environment variable on UNIX™. For a general description of how to set these environment variables on Windows™, see [Setting environment variables on Windows on page 1684](#).

---

## Environment variable portal

This portal is an index of usage categories for HCL Informix® and UNIX™ environment variables. The portal contains links to the topics that describe the environment variables.

Because the following table contains a comprehensive list of categories with links to applicable topics. Some environment variables are applicable for more than one category.

**Table 83. Uses for environment variables**

| Functional category     | Environment variable  |
|-------------------------|---|
| Abbreviated year values | Specify how to expand literal DATE and DATETIME values: <a href="#">DBCENTURY environment variable on page 1704</a>   |
| ANSI/ISO SQL compliance | <p>Set the case of owner names: <a href="#">ANSIOWNER environment variable on page 1698</a></p> <p>Specify if you want to check for HCL Informix® extensions to ANSI-standard SQL syntax: <a href="#">DBANSIWARN environment variable on page 1703</a></p> <p>No default table or routine access privileges for PUBLIC in databases not created WITH LOG MODE ANSI: <a href="#">NODEFDAC environment variable on page 1742</a></p>  |
| archecker utility       | Specify the full path name for the archecker configuration file: <a href="#">AC_CONFIG file environment variable on page</a>  |
| Buffers                 | <p>Manage the fetch buffer size: <a href="#">FET_BUF_SIZE environment variable on page 1721</a></p> <p>Manage the network size: <a href="#">IFX_NETBUF_SIZE environment variable on page 1727</a></p> <p>Manage the network pool size: <a href="#">IFX_NETBUF_PVTPOOL_SIZE environment variable (UNIX) on page 1727</a></p> <p>Manage the BYTE or TEXT data buffer: <a href="#">DBBLOBBUF environment variable on page 1704</a></p>   |
| Cache                   | Control the use of the shared-statement cache on a session: <a href="#">STMT_CACHE environment variable on page 1753</a>  |
| Client/server           | <p>Specify the default database server: <a href="#">INFORMIXSERVER environment variable on page 1736</a></p> <p>Specify where shared-memory segments are attached to the client process: <a href="#">INFORMIXSHMBASE environment variable (UNIX) on page 1737</a></p> <p>Specify the stack size for a client process: <a href="#">INFORMIXSTACKSIZE environment variable on page 1738</a></p> <p>Specify locale information, including for the client and server: <a href="#">GLS-related environment variables on page</a></p> |
| Code-set conversion     | Specify locale and multibyte information: <a href="#">GLS-related environment variables on page</a>   |

**Table 83. Uses for environment variables (continued)**

| Functional category | Environment variable   |
|---------------------|--|
|                     | <p>Specify the location of the <b>concsm.cfg</b> file:<br/> <a href="#">INFORMIXCONCSMCFG environment variable on page 1733</a></p> <p>Specify the filename or pathname of the C compiler:<br/> <a href="#">INFORMIXC environment variable (UNIX) on page 1731</a></p> <p>Specify the pathname of the map file for C++ programs:<br/> <a href="#">INFORMIXCPPMAP environment variable on page 1735</a></p> <p>Specify information for compiling multithreaded Informix® ESQL/C applications: <a href="#">THREADLIB environment variable (UNIX) on page 1754</a></p>  |
| Configuration       | <p>Specify the name of the active that holds configuration parameters: <a href="#">ONCONFIG environment variable on page 1742</a></p> <p>Ignore specified environment variable settings: <a href="#">ENVIGNORE environment variable (UNIX) on page 1721</a></p> <p>Specify the default database server: <a href="#">INFORMIXSERVER environment variable on page 1736</a></p> <p>Specify the dbspaces in which temporary tables are built: <a href="#">DBSPACETEMP environment variable on page 1716</a></p> <p>Manage query optimizer directives: <a href="#">IFX_DIRECTIVES environment variable on page 1723</a> and <a href="#">IFX_EXTDIRECTIVES environment variable on page 1724</a></p> <p>Modify the value of the OPTCOMPIND configuration parameter: <a href="#">OPTCOMPIND environment variable on page 1743</a></p> <p>Specify the query performance goal for the optimizer: <a href="#">OPT_GOAL environment variable (UNIX) on page 1745</a></p> <p>Specify the degree of parallelism that the database server uses: <a href="#">PDQPRIORITY environment variable on page 1746</a></p> <p>Specify the stack size that is applied to all client processes: <a href="#">INFORMIXSTACKSIZE environment variable on page 1738</a></p> |
| Connecting          | <p>Set the maximum number of <i>additional</i> connection attempts: <a href="#">INFORMIXCONRETRY environment variable on page 1733</a></p> <p>Set connect time information: <a href="#">INFORMIXCONTIME environment variable on page 1734</a></p>  |

**Table 83. Uses for environment variables (continued)**

| Functional category | Environment variable  |
|---------------------|---|
|                     | Specify the default database server to for connections: <a href="#">INFORMIXSERVER environment variable on page 1736</a><br>Specify the location of connection information: <a href="#">INFORMIXSQLHOSTS environment variable on page 1737</a>  |
| Connection Manager  | Specify the location of the Connection Manager configuration file: <a href="#">CMCONFIG environment variable on page 1699</a>   |
| Data distributions  | Manage the amount of system disk space that the UPDATE STATISTICS statement can use: <a href="#">DBUPSPACE environment variable on page 1717</a>  |
| Database locale     | Manage locale information: <a href="#">GLS-related environment variables on page</a>  |
| Database server     | Specify servers for connections: <a href="#">INFORMIXSERVER environment variable on page 1736</a><br>Set the locale for file I/O: <a href="#">GLS-related environment variables on page</a><br>Specify the name of the active file that holds configuration parameters: <a href="#">ONCONFIG environment variable on page 1742</a><br>Manage parallel sorting: <a href="#">PSORT_DBTEMP environment variable on page 1749</a> and <a href="#">PSORT_NPROCS environment variable on page 1750</a><br>Manage parallelism: <a href="#">PDQPRIORITY environment variable on page 1746</a><br>Manage role separation: <a href="#">INF_ROLE_SEP environment variable on page 1739</a><br>Manage shared memory: <a href="#">INFORMIXSHMBASE environment variable (UNIX) on page 1737</a><br>Manage stack size: <a href="#">INFORMIXSTACKSIZE environment variable on page 1738</a><br>Manage temporary tables: <a href="#">DBSPACETEMP environment variable on page 1716</a> , <a href="#">DBTEMP environment variable on page 1717</a> , and <a href="#">PSORT_DBTEMP environment variable on page 1749</a> |

**Table 83. Uses for environment variables (continued)**

| Functional category           | Environment variable  |
|-------------------------------|---|
|                               | Manage variable-length packets: <a href="#">IFX_PAD_VARCHAR environment variable on page 1730</a>   |
| Date and time values, formats | Manage date and time information: <a href="#">DBCENTURY environment variable on page 1704</a> , <a href="#">DBDATE environment variable on page 1707</a> , <a href="#">GLS-related environment variables on page (GL_DATE and GL_DATETIME)</a> , <a href="#">The USE_DTENV environment variable on page</a> , and <a href="#">TZ environment variable on page 1755</a>  |
| DB-Access utility             | Manage the database server and DB-Access: <a href="#">DBANSIWARN environment variable on page 1703</a> , <a href="#">DBDELIMITER environment variable on page 1709</a> , <a href="#">DBEDIT environment variable on page 1709</a> . <a href="#">DBFLTMASK environment variable on page 1710</a> , <a href="#">DBPATH environment variable on page 1713</a> , <a href="#">FET_BUF_SIZE environment variable on page 1721</a> , <a href="#">INFORMIXSERVER environment variable on page 1736</a> , <a href="#">INFORMIXTERM environment variable (UNIX) on page 1738</a> , <a href="#">TERM environment variable (UNIX) on page 1753</a> , <a href="#">TERMCAP environment variable (UNIX) on page 1753</a> , and <a href="#">TERMINFO environment variable (UNIX) on page 1754</a> |
| dbexport utility              | Set the field delimiter: <a href="#">DBDELIMITER environment variable on page 1709</a>  |
| dbinfo                        | Specify if <code>dbinfo('dbspace', partnum)</code> raises error -727 or returns NULL for an invalid partnum: <a href="#">DBINFO_DBSPACE_RETURN_NULL_FOR_INVALID_PARTNUM environment variable on page 1710</a>   |
| Delimited identifiers         | Set the field delimiter used with the dbexport utility and with the LOAD and UNLOAD statements: <a href="#">DBDELIMITER environment variable on page 1709</a>   |
| Disk space                    | Manage the amount of system disk space and memory that the UPDATE STATISTICS MEDIUM or HIGH statement can use: <a href="#">DBUPSPACE environment variable on page 1717</a>  |
| Editor                        | Specify the text editor to use with SQL statements and command files in DB-Access: <a href="#">DBEDIT environment variable on page 1709</a>   |

**Table 83. Uses for environment variables (continued)**

| Functional category    | Environment variable  |
|------------------------|---|
| Enterprise Replication | Specify information for Enterprise Replication: <a href="#">Enterprise Replication configuration parameter and environment variable reference on page</a>   |
| ESQL/C                 | <p>Specify ANSI compliance: <a href="#">DBANSIWARN environment variable on page 1703</a></p> <p>Specify the filename or pathname of the C compiler to use with ESQL/C: <a href="#">INFORMIXC environment variable (UNIX) on page 1731</a></p> <p>Set delimited identifiers: <a href="#">DELIMIDENT environment variable on page 1719</a></p> <p>Specify multibyte characters and locale information <a href="#">GLS-related environment variables on page</a> (<b>CLIENT_LOCALE, ESQLMF, and GL_USER</b>)</p> <p>Specify information for multithreaded applications: <a href="#">THREADLIB environment variable (UNIX) on page 1754</a></p> <p>Specify the default compilation order: <a href="#">CPFIRST environment variable on page 1699</a></p> |
| Executable programs    | Specify the directories to search for executable programs: <a href="#">PATH environment variable on page 1746</a>   |
| Fetch buffer size      | Set buffer size information: <a href="#">FET_BUF_SIZE environment variable on page 1721</a>   |
| Filenames: multibyte   | <a href="#">GLS-related environment variables on page</a> ( <b>GLS8BITFSYS</b> )  |
| Files: field delimiter | Set the field delimiter: <a href="#">DBDELIMITER environment variable on page 1709</a>  |
| Files: installation    | Specify the directory that contains the subdirectories in which your product files are installed: <a href="#">INFORMIXDIR environment variable on page 1736</a>   |
| Files: locale          | Specify locale information: <a href="#">GLS-related environment variables on page</a> ( <b>CLIENT_LOCALE, DB_LOCALE, and SERVER_LOCALE</b> )  |
| Files: map for C++     | Specify the pathname of the map file for C++ programs: <a href="#">INFORMIXCPPMAP environment variable on page 1735</a>   |

**Table 83. Uses for environment variables (continued)**

| Functional category            | Environment variable  |
|--------------------------------|---|
| Files: message                 | Specify the subdirectory of <b>\$INFORMIXDIR</b> or the pathname of the directory that contains the compiled message files that the database server uses: <a href="#">DBLANG environment variable on page 1711</a>  |
| Files: temporary               | <a href="#">DBSPACETEMP environment variable on page 1716</a>   |

| Virtual memory segments on large pages | Specify whether the database server can use large pages on platforms where the hardware and the operating system support large pages of shared memory: <a href="#">IFX_LARGE_PAGES environment variable on page 1725</a>   |
| Year values (abbreviated)              | Specify how to expand DATE and DATETIME values that are entered as abbreviated year values: <a href="#">DBCENTURY environment variable on page 1704</a>  |

## ANSIOWNER environment variable

In an ANSI-compliant database, you can prevent the default behavior of upshifting lowercase letters in owner names that are not delimited by quotation marks by setting the **ANSIOWNER** environment variable to 1.

```
setenvANSIOWNER 1
```

To prevent upshifting of lowercase letters in owner names in an ANSI-compliant database, you must set **ANSIOWNER** before you initialize HCL Informix®.

The following table shows how an ANSI-compliant database of HCL Informix® stores or reads the specified name of a database object called **oblong** if you were the owner of **oblong** and your **userid** (in all lowercase letters) were **owen**:

**Table 84. Lettercase of implicit, unquoted, and quoted owner names, with and without ANSIOWNER**

| Owner Format     | Specification | ANSIOWNER = 1 | ANSIOWNER Not Set |
|------------------|---------------|---------------|-------------------|
| <b>Implicit:</b> | oblong        | owen.oblong   | OWEN.oblong       |

**Table 84. Lettercase of implicit, unquoted, and quoted owner names, with and without ANSIOWNER (continued)**

| Owner Format     | Specification | ANSIOWNER = 1 | ANSIOWNER Not Set |
|------------------|---------------|---------------|-------------------|
| <b>Unquoted:</b> | owen.oblong   | owen.oblong   | OWEN.oblong       |
| <b>Quoted:</b>   | 'owen'.oblong | owen.oblong   | owen.oblong       |

Because they do not match the lettercase of your **userid**, any SQL statements that specified the formats that are stored as **OWEN.oblong** would fail with errors.

## CPFIRST environment variable

Use the **CPFIRST** environment variable to specify the default compilation order for all Informix® ESQL/C source files in your programming environment.

### **setenv**CPFIRST

**TRUE FALSE**

When you compile Informix® ESQL/C programs with **CPFIRST** not set, the Informix® ESQL/C preprocessor runs first, by default, on the program source file and then passes the resulting file to the C language preprocessor and compiler. You can, however, compile the Informix® ESQL/C program source file in the following order:

1. Run the C preprocessor
2. Run the Informix® ESQL/C preprocessor
3. Run the C compiler and linker

To use a nondefault compilation order for a specific program, you can either give the program source file a `.ecp` extension, run the `-cp` option with the **esql** command on a program source file with a `.ec` extension, or set **CPFIRST**.

Set **CPFIRST** to `TRUE` (uppercase only) to run the C preprocessor before the Informix® ESQL/C preprocessor on all Informix® ESQL/C source files in your environment, irrespective of whether the `-cp` option is passed to the **esql** command or the source files have the `.ec` or the `.ecp` extension.

To restore the default order on a system where the **CPFIRST** environment variable has been set to `TRUE`, you can set **CPFIRST** to `FALSE`. On UNIX™ systems that support the C shell, the following command has the same effect:

```
unsetenv CPFIRST
```

## CMCONFIG environment variable

Set the **CMCONFIG** environment variable to specify the location of the Connection Manager configuration file. You use the configuration file to specify service level agreements and other Connection Manager configuration options.

**setenv**CMCONFIG*path/file\_name*

***path/file\_name***

is the full path and file name of a Connection Manager configuration file.

If the CMCONFIG environment variable is not set and the configuration file name is not specified on the oncmsm utility command line, the Connection Manager attempts to load the file from the following path and file name:

```
$INFORMIXDIR/etc/cmsm.cfg
```

**Example****Examples**

Suppose the CMCONFIG environment variable points to a valid path and file name of a Connection Manager configuration file. To reload a Connection Manager instance using the configuration file specified in the shell environment enter the following command:

```
./oncmsm -r
```

To shut down a Connection Manager instance using the configuration file specified in the shell environment:

```
./oncmsm -k
```

**CLIENT\_LABEL environment variable**

Set the **CLIENT\_LABEL** environment variable in CSDK 4.10.xC10 or JDBC 4.10.JC10 client to assign a character string to CSDK or JDBC client session and identify that character string on the database server. You use this for environments where same userid runs multiple instances of the same application, and there is a need to distinguish one session from the other.

```
onstat -g env ses/D
```

```
select * from sysenvses where envses_name = CLIENT_LABEL
```

**Example****CSDK Example**

Suppose the CLIENT\_LABEL is set to two different strings and the same esqlc program is executed with the session ids being 43 and 201:

```
bash-3.2$ export CLIENT_LABEL='csdk_client1'
bash-3.2$ ./myesqlc
```

```
bash-3.2$ export CLIENT_LABEL='csdk_client2'
bash-3.2$ ./myesqlc
```

**onstat**

```
onstat -g env 43
```

```
HCL Informix Dynamic Server Version 14.10
210712 Kbytes
```

```
-- On-Line -- Up 5 days 23:01:39 --
```

```

Environment for session 43:

Variable          Value [values-list]
CLIENT_LABEL      cdsk_client2
CLIENT_LOCALE     en_US.8859-1
CLNT_PAM_CAPABLE  1
↓σνιπδ

onstat -g env 201

HCL Informix Dynamic Server Version 14.10          -- On-Line -- Up 5 days 23:02:41 --
210712 Kbytes

Environment for session 201:

Variable          Value [values-list]
CLIENT_LABEL      cdsk_client1
CLIENT_LOCALE     en_US.8859-1
CLNT_PAM_CAPABLE  1

sysmaster

select * from sysenvses where envses_name = 'CLIENT_LABEL'

envses_sid      201
envses_id       9
envses_name     CLIENT_LABEL
envses_value    cdsk_client1

envses_sid      43
envses_id       9
envses_name     CLIENT_LABEL
envses_value    cdsk_client2

2 row(s) retrieved.

Database closed.

```

**Example****JDBC Example**

Suppose the CLIENT\_LABEL is set to two different strings in the JDBC connection URL and the same JDBC program is executed with the session ids being 232 and 234:

```

java myjdbc "jdbc:informix-sqli://myhost:52220:user=myuser;password=mypasswd;CLIENT_LABEL=jdbc_client1"

java myjdbc "jdbc:informix-sqli://myhost:52220:user=myuser;password=mypasswd;CLIENT_LABEL=jdbc_client2"

```

**onstat**

```

onstat -g env 232

## DBACCNOIGN environment variable

Use the **DBACCNOIGN** environment variable to specify the behavior of the DB-Access utility when specified errors occurs.

The **DBACCNOIGN** environment variable affects the behavior of the DB-Access utility if an error occurs under one of the following circumstances:

- You run DB-Access in non-menu mode.
- In HCL Informix® only, you execute the LOAD command with DB-Access in menu mode.

Set the **DBACCNOIGN** environment variable to `1` to roll back an incomplete transaction if an error occurs while you run the DB-Access utility under either of the preceding conditions.

### **setenvDBACCNOIGN1**

For example, assume DB-Access runs the following SQL commands:

```

DATABASE mystore
BEGIN WORK

INSERT INTO receipts VALUES (cust1, 10)
INSERT INTO receipt VALUES (cust1, 20)
INSERT INTO receipts VALUES (cust1, 30)

UPDATE customer
  SET balance =
    (SELECT (balance-60)
     FROM customer WHERE custid = 'cust1')
  WHERE custid = 'cust1'
COMMIT WORK

```

Here, one statement has a misspelled table name: the **receipt** table does not exist. If **DBACCNOIGN** is not set in your environment, DB-Access inserts two records into the **receipts** table and updates the **customer** table. Now, the decrease in the **customer** balance exceeds the sum of the inserted receipts.

But if **DBACCNOIGN** is set to `1`, messages open that indicate that DB-Access rolled back all the INSERT and UPDATE statements. The messages also identify the cause of the error so that you can resolve the problem.

## LOAD statement example when DBACCNOIGN is set

You can set the **DBACCNOIGN** environment variable to protect data integrity during a LOAD statement, even if DB-Access runs the LOAD statement in menu mode.

Assume you execute the LOAD statement from the DB-Access SQL menu. Forty-nine rows of data load correctly, but the 50th row contains an invalid value that causes an error. If you set **DBACCNOIGN** to `1`, the database server does not insert the forty-nine previous rows into the database. If **DBACCNOIGN** is not set, the database server inserts the first 49 rows.

## DBANSIWARN environment variable

Use the **DBANSIWARN** environment variable to indicate that you want to check for HCL Informix® extensions to ANSI-standard SQL syntax.

Unlike most environment variables, you are not required to set

```
DBANSIWARN
```

to a value. You can set it to any value or to no value.

### setenvDBANSIWARN

Running DB-Access with **DBANSIWARN** set is functionally equivalent to including the **-ansi** flag when you invoke DB-Access (or any HCL Informix® product that recognizes the **-ansi** flag) from the command line. If you set **DBANSIWARN** before you run DB-Access, any syntax-extension warnings are displayed on the screen within the SQL menu.

At runtime, the **DBANSIWARN** environment variable causes the sixth character of the **sqlwarn** array in the SQL Communication Area (SQLCA) to be set to **w** when a statement is executed that is recognized as including any HCL Informix® extension to the ANSI/ISO standard for SQL syntax.

For details on SQLCA, see the *Informix® ESQL/C Programmer's Manual*.

After you set **DBANSIWARN**, HCL Informix® extension checking is automatic until you log out or unset **DBANSIWARN**. To turn off HCL Informix® extension checking, you can disable **DBANSIWARN** with this command:

```
unsetenv DBANSIWARN
```

## DBBLOBBUF environment variable

Use the **DBBLOBBUF** environment variable to control whether TEXT or BYTE values are stored temporarily in memory or in a file while being processed by the UNLOAD statement. **DBBLOBBUF** affects only the UNLOAD statement.

**setenvDBBLOBBUFsize**

**size**

represents the maximum size of TEXT or BYTE data in KB.

If the TEXT or BYTE data size is smaller than the default of 10 KB (or the setting of **DBBLOBBUF**), the TEXT or BYTE value is temporarily stored in memory. If the data size is larger than the default or the **DBBLOBBUF** setting, the data value is written to a temporary file. For instance, to set a buffer size of 15 KB, set **DBBLOBBUF** as in the following example:

```
setenv DBBLOBBUF 15
```

Here any TEXT or BYTE value smaller than 15 KB is stored temporarily in memory. Values larger than 15 KB are stored temporarily in a file.

## DBCENTURY environment variable

Use the **DBCENTURY** environment variable to specify how to expand literal DATE and DATETIME values that are entered with abbreviated year values. To avoid problems in expanding abbreviated years, applications should require entry of 4-digit years, and should always display years as four digits.

**setenvDBCENTURY**

**R F**

**C P**

When **DBCENTURY** is not set (or is set to **R**), the first two digits of the current year are used to expand 2-digit year values. For example, if today's date is 09/30/2003, then the abbreviated date 12/31/99 expands to 12/31/2099, and the abbreviated date 12/31/00 expands to 12/31/2000.

The R, P, F, and C settings determine algorithms for expanding two-digit years.

| Setting      | Algorithm   |
|--------------|---|
| R = Current® | Use the first two digits of the current year to expand the year value.  |
| P = Past     | Expanded dates are created by prefixing the abbreviated year value with 19 and 20. Both dates are compared to the current date, and the most recent date that is earlier than the current date is used. |
| F = Future   | Expanded dates are created by prefixing the abbreviated year value with 20 and 21. Both dates are compared to the current date, and the earliest date that is later than the current date is used.      |
| C = Closest  | Expanded dates are created by prefixing the abbreviated year value with 19, 20, and 21. These three dates are compared to the current date, and the date that is closest to the current date is used.   |

Settings are case sensitive, and no error is issued for invalid settings. If you enter `f` (for example), then the default (`R`) setting takes effect. The `P` and `F` settings cannot return the current date, which is not in the past or future.

Years entered as a single digit are prefixed with 0 and then expanded. Three-digit years are not expanded. Pad years earlier than 100 with leading zeros.

## Examples of expanding year values

The examples in this topic illustrate how various settings of **DBCENTURY** cause abbreviated years to be expanded in DATE and DATETIME values.

### DBCENTURY = P

```
Example data type: DATE
Current date: 4/6/2003
User enters: 1/1/1
Prefix with "19" expansion : 1/1/1901
Prefix with "20" expansion: 1/1/2001
Analysis: Both are prior to current date, but 1/1/2001 is closer to
current date.
```

**Important:** The effect of **DBCENTURY** depends on the current date from the system clock-calendar. Thus, 1/1/1, the abbreviated date in this example, would instead be expanded to 1/1/1901 if the current date were 1/1/2001 and **DBCENTURY = P**.

### DBCENTURY = F

```
Example data type: DATETIME year to month
Current date: 5/7/2005
User enters: 1-1
Prefix with "20" expansion: 2001-1
Prefix with "21" expansion: 2101-1
Analysis: Only date 2101-1 is after the current date, so it is chosen.
```

**DBCENTURY = C**

```

Example data type: DATE
Current date: 4/6/2000
User enters: 1/1/1
Prefix with "19" expansion : 1/1/1901
Prefix with "20" expansion: 1/1/2001
Prefix with "21" expansion: 1/1/2101
Analysis: Here 1/1/2001 is closest to the current date, so it is chosen.

```

**DBCENTURY = R or DBCENTURY Not Set**

```

Example data type: DATETIME year to month
Current date: 4/6/2000
User enters: 1-1
Prefix with "20" expansion: 2001-1

Example data type: DATE
Current date: 4/6/2003
User enters: 0/1/1
Prefix with "20" expansion: 2000/1
Analysis: In both examples, the Prefix with "20" algorithm is used.

```

Setting **DBCENTURY** does not affect HCL Informix® products when the locale specifies a non-Gregorian calendar. The leading digits of the current year are used for alternative calendar systems when the year is abbreviated.

**Abbreviated years and expressions in database objects**

When an expression in a database object (including a check constraint, fragmentation expression, SPL routine, trigger, or UDR) contains a literal date or DATETIME value in which the year has one or two digits, the database server evaluates the expression using the setting that **DBCENTURY** (and other relevant environment variables) had when the database object was created (or was last modified).

If **DBCENTURY** has been reset to a new value, the new value is ignored when the abbreviated year is expanded.

For example, suppose a user creates a table and defines the following check constraint on a column named **birthdate**:

```
birthdate < '09/25/50'
```

The expression is interpreted according to the value of **DBCENTURY** when the constraint was defined. If the table that contains the **birthdate** column is created on 09/23/2000 and **DBCENTURY =C**, the check constraint expression is consistently interpreted as `birthdate < '09/25/1950'` when inserts or updates are performed on the **birthdate** column. Even if different values of **DBCENTURY** are set when users perform inserts or updates on the **birthdate** column, the constraint expression is interpreted according to the setting at the time when the check constraint was defined (or was last modified).

Database objects created on some earlier versions of HCL Informix® do not support the priority of creation-time settings.

**For legacy objects to acquire this feature**

1. Drop the objects.
2. Recreate them (or for fragmentation expressions, detach them and then reattach them).

After the objects are redefined, date literals within expressions of the objects will be interpreted according to the environment at the time when the object was created or was last modified. Otherwise, their behavior will depend on the runtime environment and might become inconsistent if this changes.

Administration of a database that includes a mix of legacy objects and new objects might become difficult because of differences between the new and the old behavior for evaluating date expressions. To avoid this, it is recommended that you redefine any legacy objects.

The value of **DBCENTURY** and the current date are not the only factors that determine how the database server interprets date and DATETIME values. The **DBDATE**, **DBTIME**, **GL\_DATE**, and **GL\_DATETIME** environment variables can also influence how dates are interpreted. For information about **GL\_DATE** and **GL\_DATETIME**, see the *Informix® GLS User's Guide*.

**Important:** The behavior of **DBCENTURY** for HCL Informix® is not compatible with earlier versions.

## DBDATE environment variable

Use the **DBDATE** environment variable to specify the end-user formats of DATE values.

On UNIX™ systems that use the C shell, set **DBDATE** with this syntax.

**setenvDBDATE**

**MD DM Y4 Y2**

**Y4 Y2 MD DM**

**/ - . . 0**

The following formatting symbols are valid in the **DBDATE** setting:

**- . /**

are characters that can exist as separators in a date format.

**0**

indicates that no separator is displayed between time units.

**D, M**

are characters that represent the day and the month.

**Y2, Y4**

are characters that represent the year and the precision of the year.

**DBDATE** can specify the following attributes of the display format:

- The order of time units (the month, day, and year) in a date
- Whether the year is shown as two digits (Y2) or four digits (Y4)
- The separator between the month, day, and year time units

For the U.S. English locale, the default for **DBDATE** is **MDY4/**, where **M** represents the month, **D** represents the day, **Y4** represents a four-digit year, and slash (**/**) is the time-units separator (for example, **01/08/2011**). Other valid characters for the separator

are a hyphen ( - ), a period ( . ), or a zero (0). To indicate no separator, use the zero. The slash ( / ) is used by default if you attempt to specify a character other than a hyphen, period, or zero as a separator, or if you do not include any separator in the **DBDATE** specification.

If **DBDATE** is not set on the client, any **DBDATE** setting on the database server overrides the `MDY4/` default on the client. If **DBDATE** is set on the client, that value (rather than the setting on the database server) is used by the client.

The following table shows some examples of valid **DBDATE** settings and their corresponding displays for the date 8 January, 2011:

| <b>DBDATE Setting</b> | <b>Representation of January 8, 2011:</b> |  | <b>DBDATE Setting</b> | <b>Representation of January 8, 2011:</b> |
|-----------------------|---|--|-----------------------|---|
| MDY4/                 | 01/08/2011                                |  | Y2DM.                 | 11.08.01                                  |
| DMY2-                 | 08-01-11                                  |  | MDY20                 | 010811                                    |
| MDY4                  | 01/08/2011                                |  | Y4MD*                 | 2011/01/08                                |

Formats `Y4MD*` (because asterisk is not a valid separator) and `MDY4` (with no separator defined) both display the default symbol (slash) as the separator.

**Important:** If you use the Y2 format, the setting of the **DBCENTURY** environment variable can also affect how literal DATE values are evaluated in data entry.

Also, certain routines that *Informix® ESQL/C* calls can use the **DBTIME** variable, rather than **DBDATE**, to set DATETIME formats to international specifications. For more information, see the discussion of the **DBTIME** environment variable in and in the *Informix® ESQL/C Programmer's Manual*.

The setting of the **DBDATE** variable takes precedence over that of the **GL\_DATE** environment variable, and over any default DATE format that **CLIENT\_LOCALE** specifies. For information about **GL\_DATE** and **CLIENT\_LOCALE**, see the *Informix® GLS User's Guide*.

End-user formats affect the following contexts:

- When you display DATE values, HCL Informix® products use the **DBDATE** environment variable to format the output.
- During data entry of DATE values, HCL Informix® products use the **DBDATE** environment variable to interpret the input.

For example, if you specify a literal DATE value in an INSERT statement, the database server expects this literal value to be compatible with the format that **DBDATE** specifies. Similarly, the database server interprets the date that you specify as the argument to the **DATE()** function to be in **DBDATE** format.

## DATE expressions in database objects

When an expression in a database object (including a check constraint, fragmentation expression, SPL routine, trigger, or UDR) contains a literal date value, the database server evaluates the expression using the setting that **DBDATE** (or other relevant environment variables) had when the database object was created (or was last modified). If **DBDATE** has been reset to a new value, the new value is ignored when the literal DATE is evaluated.

For example, suppose **DBDATE** is set to `MDY2/` and a user creates a table with the following check constraint on the column **orderdate**:

```
orderdate < '06/25/98'
```

The date of the preceding expression is formatted according to the value of **DBDATE** when the constraint is defined. The check constraint expression is interpreted as `orderdate < '06/25/98'` regardless of the value of **DBDATE** during inserts or updates on the **orderdate** column. Suppose **DBDATE** is reset to `DMY2/` when a user inserts the value `'30/01/98'` into the **orderdate** column. The date value inserted uses the date format `DMY2/`, whereas the check constraint expression uses the date format `MDY2/`.

See [Abbreviated years and expressions in database objects on page 1706](#) for a discussion of legacy objects from earlier versions of HCL Informix® that are always evaluated according to the runtime environment. That section describes how to redefine objects so that dates are interpreted according to environment variable settings that were in effect when the object was defined (or when the object was last modified).

**Important:** The behavior of **DBDATE** for HCL Informix® is not compatible with earlier versions.

## DBDELIMITER environment variable

Set the **DBDELIMITER** environment variable to specify the field delimiter used with the **dbexport** utility and with the LOAD and UNLOAD statements.

```
setenvDBDELIMITER'delimiter'
```

### *delimiter*

is the field delimiter for unloaded data files.

The *delimiter* can be any single character, except those in the following list:

- Hexadecimal digits (0 through 9, a through f, A through F)
- Newline or `CTRL-J`
- The backslash (`\`) symbol

The vertical bar (`|` = ASCII 124) is the default. To change the field delimiter to a plus (`+`) symbol, for example, you can set **DBDELIMITER** as follows:

```
setenv DBDELIMITER '+'
```

## DBEDIT environment variable

Use the **DBEDIT** environment variable to specify the text editor to use with SQL statements and command files in DB-Access.

If **DBEDIT** is set, the specified text editor is invoked automatically. If **DBEDIT** is not, set you are prompted to specify a text editor as the default for the rest of the session.

**setenv**DBEDIT*editor*

**editor**

is the name of the text editor you want to use.

For most UNIX™ systems, the default text editor is **vi**. If you use another text editor, be sure that it creates flat ASCII files. Some word processors in *document mode* introduce printer control characters that can interfere with the operation of your HCL Informix® product.

To specify the EMACS text editor, set **DBEDIT** with the following command:

```
setenv DBEDIT emacs
```

## DBFLTMASK environment variable

The DB-Access utility displays the floating-point values of data types FLOAT, SMALLFLOAT, and DECIMAL(*p*) within a 14-character buffer. By default, DB-Access displays as many digits to the right of the decimal point as will fit into this character buffer. Therefore, the actual number of decimal digits that DB-Access displays depends on the size of the floating-point value.

To reduce the number of digits displayed to the right of the decimal point in floating-point values, set **DBFLTMASK** to the specified number of digits.

**setenv**DBFLTMASK*scale*

**scale**

is the number of decimal digits that you want the HCL Informix® client application to display in the floating-point values. Here *scale* must be smaller than 16, the default number of digits displayed.

If the floating-point value contains more digits to the right of the decimal than **DBFLTMASK** specifies, DB-Access rounds the value to the specified number of digits. If the floating-point value contains fewer digits to the right of the decimal, DB-Access pads the value with zeros. If you set **DBFLTMASK** to a value greater than can fit into the 14-character buffer, however, DB-Access rounds the value to the number of digits that can fit.

## DBINFO\_DBSPACE\_RETURN\_NULL\_FOR\_INVALID\_PARTNUM environment variable

Use the **DBINFO\_DBSPACE\_RETURN\_NULL\_FOR\_INVALID\_PARTNUM** environment variable to specify if `dbinfo('dbspace', partnum)` raises an error -727 or returns NULL when an invalid partition number (`partnum`) is provided.

```
+-DBINFO_DBSPACE_RETURN_NULL_FOR_INVALID_PARTNUM--+ '0'-----+
                                     '- '1'-'
```

A partition number is considered invalid if it resolves to a dbspace number which is not a valid dbspace in the instance. This includes the pseudo tables which are having partition numbers that would be associated with dbspace 0 which is not a (real) dbspace in an Informix instance. This reflects that pseudo tables do not directly have an on-disk representation but rather are state information from (shared) memory which are exposed via SQL.

In case of an invalid partnum the **dbinfo('dbspace', partnum)** function would result in an error '727: Invalid or NULL TBLspace number given to dbinfo(dbspace)'. When the environment variable **DBINFO\_DBSPACE\_RETURN\_NULL\_FOR\_INVALID\_PARTNUM** is set to 1, dbinfo() will not result in an error in this case, but rather does return NULL as dbspace name. When setting a value of '0' or not setting the environment variable, the default behavior returns an error -727 for an invalid partnum. In any case a NULL provided as partnum will result in error -727 being raised.

With SET ENVIRONMENT DBINFO\_DBSPACE\_RETURN\_NULL\_FOR\_INVALID\_PARTNUM the variable can be set dynamically at runtime. This overrides the current DBINFO\_DBSPACE\_RETURN\_NULL\_FOR\_INVALID\_PARTNUM value for the current user session only. For more information about the SET ENVIRONMENT DBINFO\_DBSPACE\_RETURN\_NULL\_FOR\_INVALID\_PARTNUM statement of SQL, see the [Guide to SQL: Syntax](#).

## DBLANG environment variable

Use the **DBLANG** environment variable to specify the subdirectory of **\$INFORMIXDIR** or the full pathname of the directory that contains the compiled message files that HCL Informix® products use.

### setenvDBLANG

*relative\_path full\_path*

#### ***relative\_path***

is a subdirectory of **\$INFORMIXDIR**.

#### ***full\_path***

is the pathname to the compiled message files.

By default, HCL Informix® products put compiled messages in a locale-specific subdirectory of the **\$INFORMIXDIR/msg** directory. These compiled message files have the file extension **.iem**. If you want to use a message directory other than **\$INFORMIXDIR/msg**, where, for example, you can store message files that you create, you must perform the following steps:

### To use a message directory other than \$INFORMIXDIR/msg

1. Use the **mkdir** command to create the appropriate directory for the message files.

You can make this directory under the directory **\$INFORMIXDIR** or **\$INFORMIXDIR/msg**, or you can make it under any other directory.

2. Set the owner and group of the new directory to **informix** and the access permission for this directory to [755](#).
3. Set the **DBLANG** environment variable to the new directory. If this is a subdirectory of **\$INFORMIXDIR** or **\$INFORMIXDIR/msg**, then you need only list the relative path to the new directory. Otherwise, you must specify the full pathname of the directory.

4. Copy the **.iem** files or the message files that you created to the new message directory that **\$DBLANG** specifies.

All the files in the message directory should have the owner and group **informix** and access permission `644`.

HCL Informix® products that use the default U.S. English locale search for message files in the following order:

1. In **\$DBLANG**, if **DBLANG** is set to a full pathname
2. In **\$INFORMIXDIR/msg/\$DBLANG**, if **DBLANG** is set to a relative pathname
3. In **\$INFORMIXDIR/\$DBLANG**, if **DBLANG** is set to a relative pathname
4. In **\$INFORMIXDIR/msg/en\_us/0333**
5. In **\$INFORMIXDIR/msg/en\_us.8859-1**
6. In **\$INFORMIXDIR/msg**
7. In **\$INFORMIXDIR/msg/english**

For more information about search paths for messages, see the description of **DBLANG** in the *Informix® GLS User's Guide*.

## DBMONEY environment variable

Use the **DBMONEY** environment variable to specify the display format of values in columns of **smallfloat**, **FLOAT**, **DECIMAL**, or **MONEY** data types, and of complex data types derived from any of these data types.

### setenvDBMONEY

`'$' front 'front '`

`,'`

`back 'back'`

**\$**

is a currency symbol that precedes MONEY values in the default locale if no other *front* symbol is specified, or if **DBMONEY** is not set.

**, or .**

is a comma or period (the default) that separates the integral part from the fractional part of the **FLOAT**, **DECIMAL**, or **MONEY** value. Whichever symbol you do not specify becomes the thousands separator.

**back**

is a currency symbol that follows the MONEY value.

**front**

is a currency symbol that precedes the MONEY value.

The *back* symbol can be up to seven characters and can contain any character that the locale supports, except a digit, a comma ( , ), or a period ( . ) symbol. The *front* symbol can be up to seven characters and can contain any character that the locale supports except a digit, a comma ( , ), or a period ( . ) symbol. If you specify any character that is not a letter of the alphabet for *front* or *back*, you must enclose the *front* or *back* setting between single quotation ( ' ) marks.

When you display MONEY values, HCL Informix® products use the **DBMONEY** setting to format the output. **DBMONEY** has no effect, however, on the internal format of data values that are stored in columns of the database.

If you do not set **DBMONEY**, then MONEY values for the default locale, U.S. English, are formatted with a dollar sign ( \$ ) that precedes the MONEY value, a period ( . ) that separates the integral from the fractional part of the MONEY value, and no *back* symbol. For example, 100.50 is formatted as \$100.50.

For more information about how **DBMONEY** formats MONEY values in nondefault locales, see the *Informix® GLS User's Guide*.

## DBPATH environment variable

Use the **DBPATH** environment variable to identify the database servers that contain databases. **DBPATH** can also specify a list of directories (in addition to the current directory) in which DB-Access looks for command scripts (.sql files).

The CONNECT DATABASE, START DATABASE, and DROP DATABASE statements use **DBPATH** to locate the database under two conditions:

- If the location of a database is not explicitly stated
- If the database cannot be located in the default server

The CREATE DATABASE statement does not use **DBPATH**.

To add a new **DBPATH** entry to existing entries, see [Modifying an environment-variable setting on page 1681](#).

### setenvDBPATH

```
: [16] pathname
/ /servername/full_pathname
/ /servername
```

#### **full\_pathname**

is the full path, from **root**, of a directory where .sql files are stored.

#### **pathname**

is the valid relative path of a directory where .sql files are stored.

#### **servername**

is the name of a database server where databases are stored. You cannot reference database files with a *servername*.

**DBPATH** can contain up to 16 entries. Each entry must be less than 128 characters. In addition, the maximum length of **DBPATH** depends on the hardware platform on which you set **DBPATH**.

When you access a database with the CONNECT, DATABASE, START DATABASE, or DROP DATABASE statement, the search for the database is done first in the directory or database server specified in the statement. If no database server is specified, the default database server that was specified by the **INFORMIXSERVER** environment variable is used.

If the database is not located during the initial search, and if **DBPATH** is set, the database servers and directories in **DBPATH** are searched for in the specified database. These entries are searched in the same order in which they are listed in the **DBPATH** setting.

## Using DBPATH with DB-Access

If you use DB-Access and select the **Choose** option from the **SQL** menu without having already selected a database, you see a list of all the **.sql** files in the directories listed in your **DBPATH**. After you select a database, the **DBPATH** is not used to find the **.sql** files. Only the **.sql** files in the current working directory are displayed.

## Searching local directories

### About this task

Use a pathname without a database server name to search for **.sql** scripts on your local computer. In the following example, the **DBPATH** setting causes DB-Access to search for the database files in your current directory and then in the Joachim and Sonja directories on the local computer:

```
setenv DBPATH /usr/joachim:/usr/sonja
```

As the previous example shows, if the pathname specifies a directory name but not a database server name, the directory is sought on the computer that runs the default database server that the **INFORMIXSERVER** specifies; see [INFORMIXSERVER environment variable on page 1736](#). For instance, with the previous example, if **INFORMIXSERVER** is set to **quality**, the **DBPATH** value is *interpreted*, as the following example shows, where the double slash precedes the database server name:

```
setenv DBPATH //quality/usr/joachim://quality/usr/sonja
```

## Searching networked computers for databases

### About this task

If you use more than one database server, you can set **DBPATH** explicitly to contain the database server and directory names that you want to search for databases. For example, if **INFORMIXSERVER** is set to **quality**, but you also want to search the **marketing** database server for **/usr/joachim**, set **DBPATH** as the following example shows:

```
setenv DBPATH //marketing/usr/joachim:/usr/sonja
```

## Specifying a servername

### About this task

You can set **DBPATH** to contain only database server names. This feature allows you to locate only databases; you cannot use it to locate command files.

The database administrator must include each database server mentioned by **DBPATH** in the **\$INFORMIXDIR/etc/sqlhosts** file. For information about communication-configuration files and dbservernames, see your *Informix® Administrator's Guide* and the .

For example, if **INFORMIXSERVER** is set to **quality**, you can search for a database first on the **quality** database server and then on the **marketing** database server by setting **DBPATH**, as the following example shows:

```
setenv DBPATH //marketing
```

If you use DB-Access in this example, the names of all the databases on the **quality** and **marketing** database servers are displayed with the **Select** option of the DATABASE menu.

## DBPRINT environment variable

Use the **DBPRINT** environment variable to specify the default printing program.

**setenvDBPRINT***program*

### **program**

Any command, shell script, or UNIX™ utility that produces standard ASCII output.

If you do not set **DBPRINT**, the default *program* is found in one of two places:

- For most BSD UNIX™ systems, the default program is **lpr**.
- For UNIX™ System V, the default program is usually **lp**.

Enter the following command to set the **DBPRINT** environment variable to specify **myprint** as the print program:

```
setenv DBPRINT myprint
```

## DBREMOTECMD environment variable (UNIX™)

Use the **DBREMOTECMD** environment variable to override the default remote shell to perform remote tape operations with the database server.

You can set **DBREMOTECMD** to a simple command or to a full path name.

**setenvDBREMOTECMD**

*commandpathname*

### **command**

A command to override the default remote shell.

### **pathname**

A path name to override the default remote shell.

If you do not specify the full path name, the database server searches your **PATH** for the specified *command*. You should use the full path name syntax on interactive UNIX™ platforms to avoid problems with similarly named programs in other directories and possible confusion with the *restricted shell* (*/usr/bin/rsh*).

The following command sets **DBREMOTECMD** for a simple command name:

```
setenv DBREMOTECMD rcmd
```

The next command to set **DBREMOTECMD** specifies a full path name:

```
setenv DBREMOTECMD /usr/bin/remsh
```

For more information about using remote tape devices for backups, see [Specify a remote device on page](#) .

## DBSPACETEMP environment variable

The **DBSPACETEMP** environment variable specifies the dbspaces in which temporary tables are built. The list can include standard dbspaces, temporary dbspaces, or both.

### setenvDBSPACETEMP

, *dbspace*

#### ***dbspace***

is the name of an existing standard or temporary dbspace.

You can list dbspaces, separated by colon (:) or comma (,) symbols, to designate space for temporary tables across physical storage devices. For example, the following command to set the **DBSPACETEMP** environment variable specifies three dbspaces for temporary tables:

```
setenv DBSPACETEMP sorttmp1:sorttmp2:sorttmp3
```

**DBSPACETEMP** overrides any default dbspaces that the DBSPACETEMP parameter specifies in the configuration file of the database server. For UPDATE STATISTICS operations, DBSPACETEMP is used only when you specify the HIGH keyword option.

On UNIX™ platforms, you might have better performance if the list of dbspaces in **DBSPACETEMP** is composed of chunks that are allocated as raw devices.

The number of dbspaces is limited by the maximum size of the environment variable, as defined by your operating system. Your database server does not create a dbspace specified by the environment variable if the dbspace does not exist.

The two classes of temporary tables are *explicit* temporary tables that the user creates and *implicit* temporary tables that the database server creates. Use **DBSPACETEMP** to specify the dbspaces for both types of temporary tables.

If you create an explicit temporary table with the CREATE TEMP TABLE statement and do not specify a dbspace for the table either in the IN *dbspace* clause or in the FRAGMENT BY clause, the database server uses the settings in **DBSPACETEMP** to determine where to create the table.

If you create an explicit temporary table with the SELECT INTO TEMP statement, the database server uses the settings in **DBSPACETEMP** to determine where to create the table.

If **DBSPACETEMP** is set, and the dbspaces that it lists include both logging and non-logging dbspaces, the database server stores temporary tables that implicitly or explicitly support transaction logging in a logged dbspace, and non-logging temporary tables in a non-logging dbspace.

The database server creates implicit temporary tables for its own use while executing join operations, SELECT statements with the GROUP BY clause, SELECT statements with the ORDER BY clause, and index builds.

When it creates explicit or implicit temporary tables, the database server uses disk space for writing the temporary data. If there are conflicts among settings or statement specifications for the location of a temporary table, these conflicts are resolved in this descending (highest to lowest) order of precedence:

1. On UNIX™ platforms, the operating-system directory or directories that the environment variable **PSORT\_DBTEMP** specifies, if this is set
2. The dbspace or dbspaces that the environment variable **DBSPACETEMP** specifies, if this is set
3. The dbspace or dbspaces that the ONCONFIG parameter DBSPACETEMP specifies.
4. The operating-system file space specified by the DUMPPDIR configuration parameter
5. The directory \$INFORMIXDIR/tmp (UNIX™) or \$INFORMIXDIR\tmp (Windows™).

**Important:** If the **DBSPACETEMP** environment variable is set to an invalid value, the database server defaults to the root dbspace for explicit temporary tables and to **/tmp** for implicit temporary tables, rather than to the setting of the DBSPACETEMP configuration parameter. In this situation, the database server might fill **/tmp** to the limit and eventually bring down the database server or kill the file system.

## DBTEMP environment variable

The **DBTEMP** environment variable is used by DB-Access. **DBTEMP** resembles **DBSPACETEMP**, specifying the directory in which to place temporary files and temporary tables.

**setenv DBTEMP *pathname***

***pathname***

The full path name of the directory for temporary files and tables.

For DB-Access to work correctly on Windows™ platforms, **DBTEMP** should be set to \$INFORMIXDIR/infxtmp.

The following example sets **DBTEMP** to the path name `usr/magda/mytemp` for UNIX™ systems that use the C shell:

```
setenv DBTEMP usr/magda/mytemp
```

**Important:** **DBTEMP** can point to an NFS-mounted directory only if the vendor of that NFS device is certified by .

If **DBTEMP** is not set, the database server creates temporary files in the `/tmp` directory and temporary tables in the **DBSPACETEMP** directory. See [DBSPACETEMP environment variable on page 1716](#) for the default if **DBSPACETEMP** is not set. Similarly, if you do not set **DBTEMP** on the client system, temporary files (such as those created for scroll cursors) are created in the `/tmp` directory.

You might experience unexpected behavior or failure in operations on values of large or complex data types, such as BYTE or ROW, if DBTEMP is not set.

## DBUPSPACE environment variable

Use the **DBUPSPACE** environment variable to specify the amount of system disk space and the amount of memory that the UPDATE STATISTICS MEDIUM and UPDATE STATISTICS HIGH statement can use when it reads and sorts column values to construct column distributions. The **DBUPSPACE** setting can also request SET EXPLAIN output to describe the execution path for calculating the statistical distributions.

### setenvDBUPSPACE

**1024**

*disk*

**: 15**

*: memory*

*: directive*

#### **disk**

is an unsigned integer, specifying the disk space (in KiB) to allocate for sorting in UPDATE STATISTICS MEDIUM and HIGH operations.

#### **memory**

is an unsigned integer, specifying the maximum amount of sorting memory (in MiB, in the range from 4 to 50 megabytes) to allocate without using PDQ.

#### **directive**

is an unsigned integer, encoding one of the following directives for the UPDATE STATISTICS execution plan:

- 1: Do not use any indexes for sorting. Print the entire plan for update statistics in the `sqexplain.out` file.
- 2: Do not use any indexes for sorting. Do not print the plan for update statistics.
- 3 or greater: Use available indexes for sorting. Print the entire plan for update statistics in explain output file.

For example, to set **DBUPSPACE** to 2,500 KiB of disk space and 1 megabyte of memory, enter this command:

```
setenv DBUPSPACE 2500:1
```

After you set this value, the database server will attempt to use no more than 2,500 KiB of disk space during the execution of an UPDATE STATISTICS MEDIUM or HIGH statement. If a table requires 5 megabytes of disk space for sorting, then UPDATE STATISTICS accomplishes the task in two passes; the distributions for one half of the columns are constructed with each pass. For a table of a given storage size, this parameter determines the number of passes, but no pass can write less than a full column.

If you do not set **DBUPSPACE**, the default setting is 1 megabyte (1,024 KiB) for *disk*, and 15 megabytes for *memory*. If you attempt to set the first **DBUPSPACE** parameter to any value less than 1,024 KiB, it is automatically set to 1,024 KiB, but no error message is returned. If this *disk* value is not large enough to allow more than one distribution to be constructed at a time, at least one distribution is done, even if the amount of disk space required to do this is more than what **DBUPSPACE** specifies. That is, regardless of the *disk* parameter setting for **DBUPSPACE**, the largest individual column

storage requirement of a table determines the actual upper limit on disk space for a single pass in any UPDATE STATISTICS HIGH or MEDIUM operation.

---

## DEFAULT\_ATTACH environment variable

The **DEFAULT\_ATTACH** environment variable supports the legacy behavior of Version 7.x of HCL Informix®, in which the pages of nonfragmented B-tree indexes on nonfragmented tables were stored, by default, in the same dbspace partition as the data pages. (The name "**DEFAULT\_ATTACH**" derives from an obsolete definition of an *attached index*, a term that now refers to an index whose fragmentation strategy is the same as the fragmentation strategy of its table. Do not confuse the obsolete Version 7.x definition with this current definition.)

### setenvDEFAULT\_ATTACH1

If the **DEFAULT\_ATTACH** environment variable is set to 1, then by default, the pages of nonfragmented B-tree indexes on nonfragmented tables are stored in the same partition (and in the same dbspace) that stores data pages of the table. The IN TABLE keywords of the CREATE INDEX statement are not required (but do not return an error).

Setting **DEFAULT\_ATTACH** to 1 has no effect, however, on any other types of indexes, whose pages are always stored in separate partitions from the data pages of the indexed table. These index types whose storage distribution is always different from that of their table include

- R-tree indexes,
- functional indexes,
- forest of trees indexes,
- fragmented indexes,
- and indexes on fragmented tables.

Index storage in the same partition as the data pages is supported only for nonfragmented B-tree indexes on nonfragmented tables.

If **DEFAULT\_ATTACH** is not set, then by default, any CREATE INDEX statement that does not specify IN TABLE as its Storage Options clause creates an index whose pages are stored in partitions separate from the data pages. This release of HCL Informix® can support existing indexes that were created by Version 7.x of HCL Informix®.

**Important:** Future releases of HCL Informix® might not continue to support **DEFAULT\_ATTACH**. Developing new applications that depend on this deprecated feature is not recommended.

## DELIMIDENT environment variable

The **DELIMIDENT** environment variable specifies that strings enclosed between double quotation ( " ) marks are delimited database identifiers.

The **DELIMIDENT** environment variable is also supported on client systems, where it can be set to y, to n, or to no setting.

- **y** specifies that client applications must use single quotation ( ' ) symbols to delimit character strings, and must use double quotation ( " ) symbols only around delimited SQL identifiers, which can support a larger character set than is valid in undelimited identifiers. Letters within delimited strings or delimited identifiers are case-sensitive. This is the default value for OLE DB and .NET.
- **n** specifies that client applications can use double quotation ( " ) or single quotation ( ' ) symbols to delimit character strings, but not to delimit SQL identifiers. If the database server encounters a string delimited by double or single quotation symbols in a context where an SQL identifier is required, it issues an error. An owner name that qualifies an SQL identifier can be delimited by single quotation ( ' ) symbols. You must use a pair of the same quotation symbols to delimit a character string.

This is the default value for ESQL/C, JDBC, and ODBC. APIs that have ESQL/C as an underlying layer, such as the DataBlade® API (LIBDMI), and the C++ API, behave as ESQL/C, and use 'n' as the default if no value for DELIMIDENT is specified on the client system.

- Specifying the DELIMIDENT environment variable with no value on the client system requires client applications to use the DELIMIDENT setting that is the default for their application programming interface (API).

#### setenvDELIMIDENT

No value is required; **DELIMIDENT** takes effect if it exists, and it remains in effect while it is on the list of environment variables. Removing DELIMIDENT when it is set at the server level requires restarting the server.

Delimited identifiers can include white space (such as the phrase "**Vitamin E**") or can be identical to SQL keywords, (such as "**TABLE**" or "**USAGE**"). You can also use them to declare database identifiers that contain characters outside the default character set for SQL identifiers (such as "**Column #6**"). In the default locale, this set consists of letters, digits, and the underscore ( \_ ) symbol.

Even if DELIMIDENT is set, you can use single quotation ( ' ) symbols to delimit authorization identifiers as the owner name component of a database object name, as in the following example:

```
RENAME COLUMN 'Owner'.table2.colllum3 TO column3;
```

This example is an exception to the general rule that when **DELIMIDENT** is set, the SQL parser interprets character strings delimited by single quotation symbols as string literals, and interprets character strings delimited by double quotation symbols ( " ) as SQL identifiers.

*Database identifiers* (also called *SQL identifiers*) are names for database objects, such as tables and columns. *Storage identifiers* are names for storage objects, such as dbspaces, blobspaces, and sbspaces. You cannot use **DELIMIDENT** to declare storage identifiers that contain characters outside the default SQL character set.

Delimited identifiers are case sensitive. To use delimited identifiers, applications in Informix® ESQL/C must set **DELIMIDENT** at compile time and at run time.

**Important:** If **DELIMIDENT** is not already set, you should be aware that setting it can cause the failure of existing .sql scripts or client applications that use double ( " ) quotation marks in contexts other than delimiting SQL

identifiers, such as delimiters of string literals. You must use single ( ' ) rather than double quotation marks for delimited constructs that are not SQL identifiers if **DELIMIDENT** is set.

On UNIX™ systems that use the C shell and on which **DELIMIDENT** has been set, you can disable this feature (which causes anything between double quotation symbols to be interpreted as an SQL identifier) by the command:

```
unsetenv DELIMIDENT
```

## ENVIGNORE environment variable (UNIX™)

The **ENVIGNORE** environment variable can deactivate specified environment variable settings in the common (shared) configuration file, `informix.rc`, and private environment-configuration file, `.informix`.

### **setenvENVIGNORE**

*: variable*

#### **variable**

The name of an environment variable to be deactivated.

Use colon ( : ) symbols between consecutive *variable* names. For example, to ignore the **DBPATH** and **DBMONEY** entries in the environment-configuration files, enter the following command:

```
setenv ENVIGNORE DBPATH:DBMONEY
```

The common environment-configuration file is stored in `$INFORMIXDIR/etc/informix.rc`.

The private environment-configuration file is stored in the home directory of the user as `.informix`.

For information about creating or modifying an environment-configuration file, see [Setting environment variables in a configuration file on page 1679](#).

**ENVIGNORE** itself cannot be set in an environment-configuration file.

## FET\_BUF\_SIZE environment variable

The **FET\_BUF\_SIZE** environment variable can override the default setting for the size of the fetch buffer for all data types except BYTE and TEXT values. For ANSI databases, you must set transactions to READ ONLY for the **FET\_BUF\_SIZE** environment variable to improve performance, otherwise rows are returned one by one.

### **setenvFET\_BUF\_SIZEsize**

#### **size**

is a positive integer that is larger than the default buffer size, but no greater than 2147483648 (2GB), specifying the size (in bytes) of the fetch buffer that holds data retrieved by a query.

For example, to set a buffer size to 5,000 bytes on a UNIX™ system that uses the C shell, set **FET\_BUF\_SIZE** by entering the following command:

```
setenv FET_BUF_SIZE 5000
```

When **FET\_BUF\_SIZE** is set to a valid value, the new value overrides the default value (or any previously set value of **FET\_BUF\_SIZE**). The default setting for the fetch buffer is dependent on row size.

The processing of **BYTE** and **TEXT** values is not affected by **FET\_BUF\_SIZE**.

No error is raised if **FET\_BUF\_SIZE** is set to a value that is less than the default size or is larger than 2147483648 (2GB). In these cases, however, the invalid fetch buffer size is ignored, and the default size is in effect.

A valid **FET\_BUF\_SIZE** setting is in effect for the local database server and for any remote database server from which you retrieve rows through a distributed query in which the local server is the coordinator and the remote database is subordinate. The greater the size of the buffer, the more rows can be returned, and the less frequently the client application must wait while the database server returns rows. A large buffer can improve performance by reducing the overhead of filling the client-side buffer.

## IFMXMONGOAUTH environment variable

Set the **IFMXMONGOAUTH** environment variable to enable PAM authentication for MongoDB clients through the wire listener.

You can set the **IFMXMONGOAUTH** environment variable to any value or to no value.

```
setenv IFMXMONGOAUTH 1
```

Setting the **IFMXMONGOAUTH** environment variable is a prerequisite to configuring PAM authentication for MongoDB clients.

You can disable the **IFMXMONGOAUTH** environment variable with this command:

```
unsetenv IFMXMONGOAUTH
```

## IFX\_DEF\_TABLE\_LOCKMODE environment variable

The **IFX\_DEF\_TABLE\_LOCKMODE** environment variable can specify the default lock mode for database tables that are subsequently created without explicitly specifying the **LOCKMODE PAGE** or **LOCKMODE ROW** keywords. This feature is convenient if you must create several tables of the same lock mode. UNIX™ systems that use the C shell support the following syntax:

```
setenv IFX_DEF_TABLE_LOCKMODE
```

**PAGE ROW**

**PAGE**

The default lock mode is page-level granularity. This value disables the **LAST COMMITTED** feature of **COMMITTED READ**.

## ROW

The default lock mode is row-level granularity.

Similar functionality is available by setting the `DEF_TABLE_LOCKMODE` parameter of the `ONCONFIG` file to `PAGE` or `ROW`. When a table is created or modified, any conflicting lock mode specifications are resolved according to the following descending (highest to lowest) order of precedence:

1. Explicit `LOCKMODE` specification of `CREATE TABLE` or `ALTER TABLE`
2. **`IFX_DEF_TABLE_LOCKMODE`** environment variable setting
3. `DEF_TABLE_LOCKMODE` parameter setting in the `ONCONFIG` file
4. The system default lock mode (= page mode)

To make the `DEF_TABLE_LOCKMODE` setting the default mode (or to restore the system default if `DEF_TABLE_LOCKMODE` is not set) use the command:

```
unsetenv IFX_DEF_TABLE_LOCKMODE
```

If **`IFX_DEF_TABLE_LOCKMODE`** is set in the environment of the database server before running `oninit`, then its scope is all sessions of the database server (just as if `DEF_TABLE_LOCKMODE` were set in the `ONCONFIG` file). If **`IFX_DEF_TABLE_LOCKMODE`** is set in the shell, or in the `$HOME/.informix` or `$INFORMIXDIR/etc/informix.rc` files, then the scope is restricted to the current session (if you set it in the shell) or to the individual user.

**Important:** This has no effect on existing tables. If you specify `ROW` as the lock mode, the database will use this to restore, recover, or copy data. For tables that were created in `PAGE` mode, this might cause lock-table overflow or performance degradation.

## IFX\_DIRECTIVES environment variable

The **`IFX_DIRECTIVES`** environment variable setting determines whether the optimizer allows query optimization directives from within a query. The **`IFX_DIRECTIVES`** environment variable is set on the client.

You can specify either `ON` and `OFF` or `1` and `0` to set the environment variable.

```
setenvIFX_DIRECTIVES
```

```
1 0
```

```
1
```

Optimizer directives accepted

```
0
```

Optimizer directives not accepted

The setting of the **`IFX_DIRECTIVES`** environment variable overrides the value of the `DIRECTIVES` configuration parameter that is set for the database server. If the **`IFX_DIRECTIVES`** environment variable is not set, however, then all client sessions will

inherit the database server configuration for directives that the ONCONFIG parameter DIRECTIVES determines. The default setting for the **IFX\_DIRECTIVES** environment variable is **ON**.

For more information about the DIRECTIVES parameter, see the . For more information about the performance impact of directives, see your *Informix® Performance Guide*.

## IFX\_EXTDIRECTIVES environment variable

The **IFX\_EXTDIRECTIVES** environment variable specifies whether the query optimizer allows external query optimization directives from the **sysdirectives** system catalog table to be applied to queries in existing applications.

You have two options for setting the **IFX\_EXTDIRECTIVES** environment variable:

- Global, for all users:
  - On the server, set **IFX\_EXTDIRECTIVES** in the environment as user informix and then run the oninit command.
- Client specific:
  - On the client, set **IFX\_EXTDIRECTIVES** in the environment. When **IFX\_EXTDIRECTIVES** is set in the client environment, the client setting are used regardless of the server (global) setting.

You can determine the server setting using the onstat -g env command.

You can specify either **ON** and **OFF** or **1** and **0** to set the environment variable.

### setenvIFX\_DIRECTIVES

#### 1 0

#### 1

External optimizer directives accepted

#### 0

External optimizer directives not accepted

Queries within a given client application can use external directives if both the EXT\_DIRECTIVES parameter in the configuration file of the database server and the **IFX\_EXTDIRECTIVES** environment variable setting on the client system are both set to 1 or ON. If **IFX\_EXTDIRECTIVES** is not set, external directives are supported only if the ONCONFIG parameter EXT\_DIRECTIVES is set to 2. The following table summarizes the effect of valid IFX\_EXTDIRECTIVES and EXT\_DIRECTIVES settings on support for external optimizer directives.

**Table 85. Effect of IFX\_EXTDIRECTIVES and EXT\_DIRECTIVES settings on external directives**

|                                     | EXT_DIRECTIVES = 0 | EXT_DIRECTIVES = 1 | EXT_DIRECTIVES = 2 |
|-------------------------------------|--------------------|--------------------|--------------------|
| <b>IFX_EXTDIRECTIVES No setting</b> | OFF                | OFF                | ON                 |
| <b>IFX_EXTDIRECTIVES0 = OFF</b>     | OFF                | OFF                | OFF                |

**Table 85. Effect of IFX\_EXTDIRECTIVES and EXT\_DIRECTIVES settings on external directives (continued)**

|                         | EXT_DIRECTIVES = 0 | EXT_DIRECTIVES = 1 | EXT_DIRECTIVES = 2 |
|-------------------------|--------------------|--------------------|--------------------|
| IFX_EXTDIRECTIVES1 = ON | OFF                | ON                 | ON                 |

The database server interprets any EXT\_DIRECTIVES setting besides 1 or 2 (or no setting) as equivalent to OFF, disabling support for external directives. Any value of IFX\_EXTDIRECTIVES other than 1 has the same effect for the client.

For information about how to define external optimizer directives, see the description of the SAVE EXTERNAL DIRECTIVES statement of SQL in the *Informix® Guide to SQL: Syntax*. For more information about the EXT\_DIRECTIVES configuration parameter, see the . For more information about the performance impact of directives, see your *Informix® Performance Guide*.

## IFX\_LARGE\_PAGES environment variable

The **IFX\_LARGE\_PAGES** environment variable specifies whether the database server can use large pages on platforms where the hardware and the operating system support large pages of shared memory. If this is enabled in the server environment, HCL Informix® can use the large pages for non-message shared memory segments that are located in physical memory.

The **IFX\_LARGE\_PAGES** environment variable is supported only on AIX®, Solaris, and Linux™ operating systems. The setting of **IFX\_LARGE\_PAGES** has no effect on Informix® if the operating system does not support large pages, or if large pages are not configured on the system.

You can specify either `1` or `0` to set this environment variable.

### setenvIFX\_LARGE\_PAGES

**1 0**

**0**

The use of large pages is disabled. This is the default on AIX® systems.

**1**

The use of large pages is enabled. This is the default on Solaris and Linux™ systems.

The DBSA must use operating system commands to configure the large pages. See the operating system documentation for the configuration procedures.

Informix® can use large pages for non-message shared memory segments that are locked in physical memory, if sufficient large pages are configured and available. The RESIDENT configuration parameter controls whether a shared memory segment is locked in physical memory, so that the segment cannot be swapped. If there are insufficient large pages to hold a segment, the segment might contain a mixture of large pages and regular pages.

On AIX® the large pages used by Informix® are 16 MB in size.

On Linux™ x86\_64 the large pages used by Informix® are defined by the `Hugepagesize` entry in the `/proc/meminfo` file.

Informix® aligns the segment address and rounds up to the segment size automatically. In addition to messages regarding rounding, the server prints an informational message to the server log file whenever it attempts to use large pages to store a segment.

When **IFX\_LARGE\_PAGES** is enabled, the use of large pages can offer significant performance benefits in large memory configurations.

---

## IFX\_LOB\_XFERSIZE environment variable

Use the **IFX\_LOB\_XFERSIZE** environment variable to specify the number of bytes in a CLOB or BLOB data type to transfer from a client application to the database server before checking whether an error has occurred.

The error check occurs each time the specified number of bytes is transferred. If an error occurs, the remaining data is not sent and an error is reported. If no error occurs, the file transfer will continue until it finishes.

For example, if the value of **IFX\_LOB\_XFERSIZE** is set to 10485760 (10 MB), then error checking will occur after every 10485760 bytes of the CLOB or BLOB data is sent. If **IFX\_LOB\_XFERSIZE** is not set, the error check occurs after the entire BLOB or CLOB data is transferred.

The valid range for **IFX\_LOB\_XFERSIZE** is from 1 to 9223372036854775808 bytes. The **IFX\_LOB\_XFERSIZE** environment variable is set on the client.

**setenv**IFX\_LOB\_XFERSIZE*value*

### **value**

the number of bytes in a CLOB or BLOB to transfer from a client application to the database server before checking whether an error has occurred

You should adjust the value of **IFX\_LOB\_XFERSIZE** to suit your environment. Set **IFX\_LOB\_XFERSIZE** low enough so that transmission errors of large BLOB or CLOB data types are detected early, but not so low that excessive network resources are used.

## IFX\_LONGID environment variable

The **IFX\_LONGID** environment variable setting and the version number of the client application determine whether a given client application is capable of handling long identifiers. (Older versions of HCL Informix® restricted SQL identifiers to 18 or fewer bytes; *long identifiers* can have up to 128 bytes when **IFX\_LONGID** is set.) Valid **IFX\_LONGID** values are **1** and **0**.

**setenv**IFX\_LONGID

**1 0**

**1**

Client supports long identifiers.

**0**

Client cannot support long identifiers.

When **IFX\_LONGID** is set to zero, applications display only the first 18 bytes of long identifiers, without indicating (by `+`) that truncation has occurred.

If **IFX\_LONGID** is unset or is set to a value other than `1` or `0`, the determination is based on the internal version of the client application. If the (server-based) version is not less than 9.0304, or is in the (CSDK-based) range  $2.90 \leq \text{version} < 4.0$ , the client is considered capable of handling long identifiers. Otherwise, the client application is considered incapable.

The **IFX\_LONGID** setting overrides the internal version of the client application. If the client cannot handle long identifiers despite a newer version number, set **IFX\_LONGID** to `0`. If the client version can handle long identifiers despite an older version number, set **IFX\_LONGID** to `1`.

If you set **IFX\_LONGID** on the client, the setting affects only that client. If you start the database server with **IFX\_LONGID** set, all client applications use that setting by default. If **IFX\_LONGID** is set to different values on the client and on the database server, however, the client setting takes precedence.

**Important:** ESQL executables that have been built with the `-static` option using the `libos.a` library version that does not support long identifiers cannot use the **IFX\_LONGID** environment variable. You must recompile such applications with the new `libos.a` library that includes support for long identifiers. Executables that use shared libraries (no `-static` option) can use **IFX\_LONGID** without recompilation provided that they use the new `libifos.so` that provides support for long identifiers. For details, see your ESQL product publication.

## IFX\_NETBUF\_PVTPOOL\_SIZE environment variable (UNIX™)

Use the **IFX\_NETBUF\_PVTPOOL\_SIZE** environment variable to specify the maximum size of the free (unused) private network buffer pool for each database server session.

**setenv****IFX\_NETBUF\_PVTPOOL\_SIZE***count*

**count**

an integer specifying the number of units (buffers) in the pool.

The default size is 1 buffer. If **IFX\_NETBUF\_PVTPOOL\_SIZE** is set to 0, then each session obtains buffers from the free global network buffer pool. You must specify the value in decimal form.

## IFX\_NETBUF\_SIZE environment variable

Use the **IFX\_NETBUF\_SIZE** environment variable to configure the network buffers to the optimum size. This environment variable specifies the size of all network buffers in the free (unused) global pool and the private network buffer pool for each database server session.

**setenv**IFX\_NETBUF\_SIZE*size***size**

is the integer size (in bytes) for one network buffer.

The default size is 4 KB (4,096 bytes). The maximum size is 64 KB (65,536 bytes) and the minimum size is 512 bytes. You can specify the value in hexadecimal or decimal form.

**Tip:** You cannot set a different size for each session.

**IFX\_NO\_SECURITY\_CHECK** environment variable (UNIX™)

The **IFX\_NO\_SECURITY\_CHECK** environment variable allows user **informix** or **root** to complete operations with a database server instance even when the HCL Informix® utilities detect that the `$INFORMIXDIR` path is not secure. Do not use this environment variable unless your system setup makes it absolutely necessary to do so.

The purpose of **IFX\_NO\_SECURITY\_CHECK** is for environments where the database server started but while running it detects that the runtime path is not secure anymore. In this case, a superuser might be required to stop the database server in order to remedy the security flaw. With this environment variable, either user **informix** or **root** can use the onmode utility to shut down a nonsecure Informix® instance, which would otherwise not be possible because key programs do not run when the `$INFORMIXDIR` path is not secure.

There is some risk in using this environment variable, but in some circumstances it might be necessary to remedy a bigger security problem. The requirement that only user **informix** or **root** can invoke **IFX\_NO\_SECURITY\_CHECK** makes it unlikely that an illegitimate user would be able to run it.

To use this environment variable, set it to any non-empty string.

**setenv**IFX\_NO\_SECURITY\_CHECK*1***1**

Any value entered here when running this environment variable disables the onsecurity utility.

**Important:** Turn off this environment variable after you have finished troubleshooting the security problem.

**IFX\_NO\_TIMELIMIT\_WARNING** environment variable

Trial or evaluation versions of HCL Informix® software products, which cease to function when some time limit has elapsed since the software was installed, by default issue warning messages that tell users when the license will expire. If you set the **IFX\_NO\_TIMELIMIT\_WARNING** environment variable, however, the time-limited software does not issue these warning messages.

**setenv**IFX\_NO\_TIMELIMIT\_WARNING

For users who dislike viewing warning messages, this feature is an alternative to redirecting the error output. Setting **IFX\_NO\_TIMELIMIT\_WARNING** has no effect, however, on when a time-limited license expires; the software ceases to function at the same point in time when it would if this environment variable had not been set. If you do set **IFX\_NO\_TIMELIMIT\_WARNING**, users will not see potentially annoying warnings about the impending license expiration, but some users might be annoyed at you when the database server (or whatever software has a time-limited license) ceases to function without any warning.

## IFX\_NODBPROC environment variable

The **IFX\_NODBPROC** environment variable lets you prevent the database server from running the `sysdbopen()` or `sysdbclose()` procedure. These procedures cannot be run if this environment variable is set to any value.

**setenv****IFX\_NODBPROC***string*

*string*

Any value prevents the database server from running `sysdbopen()` or `sysdbclose()`.

## IFX\_NOT\_STRICT\_THOUS\_SEP environment variable

HCL Informix® requires the thousands separator to have 3 digits following it. For example, 1,000 is considered correct, and 1,00 is considered wrong. In previous releases, both formats were considered correct.

**setenv****IFX\_NOT\_STRICT\_THOUS\_SEP***n*

*n*

Set *n* to 1 for the behavior in previous releases, which is that the thousands separator can have fewer than three digits following it.

## IFX\_ONTAPE\_FILE\_PREFIX environment variable

When `TAPEDEV` and `LTAPEDEV` specify directories, use the **IFX\_ONTAPE\_FILE\_PREFIX** environment variable to specify a prefix for backup file names that replaces the `hostname_servernum` format. If no value is set, file names are `hostname_servernum_Ln` for levels and `hostname_servernum_Lognnnnnnnnnn` for log files.

If you set the value of `IFX_ONTAPE_FILE_PREFIX` to `My_Backup`, the backup file names have the following names:

- `My_Backup_L0`
- `My_Backup_L1`
- `My_Backup_L2`
- `My_Backup_Log0000000001`
- `My_Backup_Log0000000002`

**setenv**IFX\_ONTAPE\_FILE\_PREFIX*string*

**string**

The prefix to use for the names of backup files.

## IFX\_PAD\_VARCHAR environment variable

The **IFX\_PAD\_VARCHAR** environment variable setting controls how the database server sends and receives VARCHAR and NVARCHAR data values. Valid **IFX\_PAD\_VARCHAR** values are **1** and **0**.

**setenv**IFX\_PAD\_VARCHAR

**1 0**

**1**

Transmit the entire structure, up to the declared *max* size.

**0**

Transmit only the portion of the structure containing data.

For example, to send the string "ABC" from a column declared as NVARCHAR(255) when **IFX\_PAD\_VARCHAR** is set to 0 would send 3 bytes.

If the setting were 1 in the previous example, however, the number of bytes sent would be 255 bytes.

The effect **IFX\_PAD\_VARCHAR** is context-sensitive. In a low-bandwidth network, a setting of 0 might improve performance by reducing the total volume of transmitted data. But in a high-bandwidth network, a setting of 1 might improve performance, if the CPU time required to process variable-length packets were greater than the time required to send the entire character stream. In cross-server distributed operations, this setting has no effect, and padding characters are dropped from VARCHAR or NVARCHAR values that are passed between database servers.

## IFX\_UPDDESC environment variable

You must set the **IFX\_UPDDESC** environment variable at execution time before you can do a DESCRIBE of an UPDATE statement.

**setenv**IFX\_UPDDESC*value*

**value**

is any non-NULL value.

A NULL value (here meaning that **IFX\_UPDDESC** is not set) disables the describe-for-update feature. Any non-NULL value enables the feature.

## IFX\_XASTDCOMPLIANCE\_XAEND environment variable

In earlier releases of HCL Informix®, an internal rollback of a global transaction freed the transaction. In releases later than Version 9.40, however, the default behavior after an internal rollback is not to free the global transaction until an explicit rollback, as required by the X/Open XA standard. By setting the `DISABLE_B162428_XA_FIX` configuration parameter to 1, you can restore the legacy behavior as the default for all sessions.

The **IFX\_XASTDCOMPLIANCE\_XAEND** environment variable can override the configuration parameter for the current session, using the following syntax. Valid **IFX\_XASTDCOMPLIANCE\_XAEND** values are 1 and 0.

**setenvIFX\_XASTDCOMPLIANCE\_XAEND**

**1 0**

**0**

Frees global transactions only after an explicit rollback

**1**

Frees global transactions after any rollback

This environment variable can be particularly useful when the server instance is disabled for new behavior by the `DISABLE_B162428_XA_FIX` configuration parameter, but one client requires the new behavior. Setting this environment variable to zero supports the new behavior in the current session.

## IFX\_XFER\_SHMBASE environment variable

An alternative base address for a utility to attach the server shared memory segments.

**setenvIFX\_XFER\_SHMBASE**

**address**

**address**

Valid address in hexadecimal

After the database server allocates shared memory, the database server might allocate multiple contiguous OS shared memory segments. The client utility that connects to shared memory must attach all those OS segments contiguously also. The utility might have some other shared objects (for example, the `xbsa` library in `onbar`) loaded at the address where the server has shared memory segment attached. To workaround this situation, you can specify a different base address in the environment variable `IFX_XFER_SHMBASE` for the utility to attach the shared memory segments. The `onstat`, `onmode`, and `oncheck` utilities must attach to exact same shared memory base as `oninit`. Setting `IFX_XFER_SHMBASE` is not an option for these utilities.

## INFORMIXC environment variable (UNIX™)

The **INFORMIXC** environment variable specifies the filename or pathname of the C compiler to be used to compile files that Informix® ESQL/C generates. The setting takes effect only during the C compilation stage.

If **INFORMIXC** is not set, the default compiler on most systems is **cc**.

 **Tip:** On Windows™, you pass either `-mcc` or `-bcc` options to the `esql` preprocessor to use either the Microsoft™ or Borland C compilers.

### **setenvINFORMIXC**

*compiler pathname*

#### ***compiler***

The file name of the C compiler.

#### ***pathname***

The full path name of the C compiler.

For example, to specify the GNU C compiler, enter the following command:

```
setenv INFORMIXC gcc
```

 **Important:** If you use **gcc**, be aware that the database server assumes that strings are writable, so you must compile by using the `-fwritable-strings` option. Failure to do so can produce unpredictable results, possibly including core dumps.

## INFORMIXCMNAME environment variable

If the Connection Manager raises an event alarm, the **INFORMIXCMNAME** environment variable is used to store the name of the Connection Manager instance that raised the alarm. The environment variable is set automatically by the Connection Manager.

The **INFORMIXCMNAME** environment variable corresponds to the **NAME** parameter in the Connection Manager configuration file. The environment variable is used by the **CMALARMPROGRAM** program to determine the Connection Manager instance responsible for the event alarm. You can also use the environment variable in your own Connection Manager event alarm handler.

The environment variable is set automatically by the Connection Manager and should not be modified.

---

#### **Related reference**

[INFORMIXCMCONUNITNAME environment variable on page 1732](#)

## INFORMIXCMCONUNITNAME environment variable

If the Connection Manager raises an event alarm, the `INFORMIXCMCONUNITNAME` environment variable is used to store the name of the Connection Manager connection unit that raised the alarm. The environment variable is set automatically by the Connection Manager.

The `INFORMIXCMCONUNITNAME` environment variable corresponds to the connection unit name parameter in the Connection Manager configuration file. The environment variable is used by the `CMALARMPROGRAM` program to determine the Connection Manager instance responsible for the event alarm. You can also use the environment variable in your own Connection Manager event alarm handler.

The environment variable is set automatically by the Connection Manager and should not be modified.

---

[INFORMIXCMNAME environment variable on page 1732](#)

## INFORMIXCONCSMCFG environment variable

Use the `INFORMIXCONCSMCFG` environment variable to specify the location of the `concsm.cfg` file that describes communications support modules.

`setenv INFORMIXCONCSMCFG pathname`

### *pathname*

specifies the full pathname of the `concsm.cfg` file.

The following command specifies that the `concsm.cfg` file is in `/usr/myfiles`:

```
setenv INFORMIXCONCSMCFG /usr/myfiles
```

You can also specify a different name for the file. The following example specifies a filename of `csmconfig` in the same directory:

```
setenv INFORMIXCONCSMCFG /usr/myfiles/csmconfig
```

The default location of the `concsm.cfg` file is in `$INFORMIXDIR/etc`. For more information about communications support modules and the contents of the `concsm.cfg` file, see the .

## INFORMIXCONRETRY environment variable

The `INFORMIXCONRETRY` environment variable sets a limit on the maximum number of connection attempts that can be made to each database server by the client after the initial connection attempt fails. These attempts are made within the time limit that the `INFORMIXCONTIME` setting specifies.

`setenv INFORMIXCONRETRY count`

**count**

The number of additional attempts to connect to each database server after the initial connection attempt fails.

For example, the following command sets **INFORMIXCONRETRY** to specify three connection attempts after the initial attempt:

```
setenv INFORMIXCONRETRY 3
```

The default value for **INFORMIXCONRETRY** is one attempt after the initial connection attempt.

**Order of precedence among INFORMIXCONRETRY settings**

When you specify a setting for the **INFORMIXCONRETRY** client environment variable, it overrides any **INFORMIXCONRETRY** configuration parameter setting in the `onconfig` file.

If the SET ENVIRONMENT statement specifies a setting for the **INFORMIXCONRETRY** session environment option, however, the SQL statement setting overrides the **INFORMIXCONRETRY** client environment variable setting for subsequent connection attempts during the current session. The SET ENVIRONMENT **INFORMIXCONRETRY** setting has no effect on other sessions.

In summary, this is the ascending order (lowest to highest) of the methods for setting a limit on attempts for a connection to a database server:

- **INFORMIXCONRETRY** configuration parameter
- **INFORMIXCONRETRY** client environment variable
- SET ENVIRONMENT **INFORMIXCONRETRY** statement of SQL

The **INFORMIXCONTIME** setting takes precedence over the **INFORMIXCONRETRY** setting. Connection attempts can end after the **INFORMIXCONTIME** value is exceeded, but before the **INFORMIXCONRETRY** value is reached. For more information about restricting the time available to establish a connection to a database server, see [INFORMIXCONTIME environment variable on page 1734](#)

---

**INFORMIXCONTIME environment variable**

The **INFORMIXCONTIME** environment variable specifies the number of seconds the CONNECT statement attempts to establish a connection to a database server before returning an error. If you set no value, the default of 60 seconds can typically support a few hundred concurrent client connections. However, some systems might encounter few connection errors with a value as low as 15. The total distance between nodes, hardware speed, the volume of traffic, and the concurrency level of the network can all affect what value you should set to optimize **INFORMIXCONTIME**.

The **INFORMIXCONTIME** and **INFORMIXCONRETRY** environment variables let you configure your client-side connection capability to retry the connection instead of returning a **-908** error.

**setenv****INFORMIXCONTIME***seconds*

**seconds**

Represents the minimum number of seconds spent in attempts to establish a connection to a database server.

For example, enter this command to set **INFORMIXCONTIME** to 60 seconds:

```
setenv INFORMIXCONTIME 60
```

If **INFORMIXCONTIME** is set to 60 and **INFORMIXCONRETRY** is set to 3, attempts to connect to the database server (after the initial attempt at 0 seconds) are made at 20, 40, and 60 seconds, if necessary, before aborting. This 20-second interval is the result of **INFORMIXCONTIME** divided by **INFORMIXCONRETRY**. If you set the **INFORMIXCONTIME** value to zero, the database server automatically uses the default value of 60 seconds.

If the **CONNECT** statement must search **DBPATH**, the **INFORMIXCONRETRY** setting specifies the number of additional connection attempts that can be made for each database server entry in **DBPATH**.

- All appropriate servers in the **DBPATH** setting are accessed at least once, even if the **INFORMIXCONTIME** value is exceeded. Thus, the **CONNECT** statement might take longer than the **INFORMIXCONTIME** time limit to return an error that indicates connection failure or that the database was not found.
- The **INFORMIXCONTIME** value is divided among the number of database server entries that are specified in **DBPATH**. Thus, if **DBPATH** contains numerous servers, increase the **INFORMIXCONTIME** value accordingly. For example, if **DBPATH** contains three entries, to spend at least 30 seconds attempting each connection, set **INFORMIXCONTIME** to 90.

The **INFORMIXCONTIME** and **INFORMIXCONRETRY** environment variables can be modified with the **onutil** SET command, as in the following example:

```
% onutil
1> SET INFORMIXCONTIME 120;
Dynamic Configuration completed successfully
2> SET INFORMIXCONRETRY 10;
Dynamic Configuration completed successfully
```

### Order of precedence among **INFORMIXCONTIME** settings

When you specify a setting for the **INFORMIXCONTIME** client environment variable, it overrides the **INFORMIXCONTIME** configuration parameter settings in the **onconfig** file for the current session.

If the **SET ENVIRONMENT** statement specifies a setting for the **INFORMIXCONRETRY** session environment option, however, the SQL statement setting overrides the **INFORMIXCONRETRY** client environment variable setting for subsequent connection attempts during the current session. The **SET ENVIRONMENT INFORMIXCONRETRY** setting has no effect on other sessions.

In summary, this is the ascending order (lowest to highest) of the methods for setting an upper limit on the amount of time that a **CONNECT** statement can spend attempting to connect to a database server:

- **INFORMIXCONTIME** configuration parameter
- **INFORMIXCONTIME** client environment variable
- **SET ENVIRONMENT INFORMIXCONTIME** statement of SQL.

**INFORMIXCONTIME** takes precedence over the **INFORMIXCONRETRY** setting. Connection attempts can end after the **INFORMIXCONTIME** value is exceeded, but before the **INFORMIXCONRETRY** value is reached.

## INFORMIXCPPMAP environment variable
